Diagnosis.- This and the following nine species form a more or less distinct group within the genus that is exceedingly difficult to classify. In general, characters that distinguish species are found only in the male; the females differ from one another, but by such minute characters their use in a key is impractical.
This species may be distinguished from the closely allied minulus Wood by characters summarized in the above key.

Male.- Length 0.8-1.2 mm, 2.3 (female 2.7) times as long as wide; color very dark brown.

Frons convex, weakly impressed just above epistoma; surface somewhat rugose-reticulate, minute punctures and granules obscure; vestiture of sparse, coarse setae. Antennal scape elongate, slender; club small, oval, devoid of sutures.

Pronotum 0.96 times as long as wide; subcircular in outline; anterior margin armed by four teeth; summit high, at middle, anterior slope coarsely, sparsely asperate; posterior area almost smooth, with a few minute,
obscure punctures. Vestiture of sparse, stout setae.

Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, punctures minute; interstriae almost smooth, punctures uniseriate, fine on anterior half, becoming granulate posteriorly. Declivity convex, rather steep, as on posterior part of disc. Vestiture of rows of minute strial hair and rows of erect interstrial scales, each scale about six times as long as wide, as long as distance between rows, spaced within a row by a slightly greater distance.

Female.- Similar to male except more slender; frons somewhat flattened; anterior margin of pronotum unarmed; strial punctures virtually obsolete; interstrial punctures small, obscure, not granulate except minutely on declivity; elytral scales slightly longer, more slender, at least eight times as long as wide.
Distribution.- Puebla.
MEXICO: Puebla: Tecamachalco, 2-VII-53, 2100 m , Yucca, S. L. Wood; 3 km E Tehuacán, 8-VII-67, 2000 m , No. 176, Yucca leaves, S. L. Wood.

Host.- Yucca sp.
Biology.- Recently dead or dying leaves on a healthy, living plant were selected for attack. Entrance tunnels usually were found on the lower side of the leaf. The irregular larval and adult tunnels mined the tissues between the upper and lower epidermis.

Notes.- The above treatment was based on 3 paratypes and on 69 other specimens.

## 56. Pseudothysanoes minulus (Wood)

Cryptocleptes minulus Wood, 1956, Canadian Ent. 88:238 (Holotype, 10 km W Zanatepec, Oaxaca, Mexico: Snow Ent. Mus., Univ. Kansas)
Diagnosis.- This species may be distinguished from the closely allied yuccae Wood by characters summarized in the above key and in the following description.

Male.-Length $0.7-1.0 \mathrm{~mm}, 2.3$ (female 2.8) times as long as wide; color very dark brown.

Frons as in yuccae except more shining and with a small, narrow, median impression. Pronotum also as in yuccae except more brightly shining, vestiture finer.

Elytra as in yuccae except interstrial granules very slightly larger and extending to anterior fourth, larger on declivity. Declivital scales three to four times as long as wide, slightly more slender on disc.

Female.- Similar to female of yuccae except median fourth of frons sharply, rather shallowly impressed from epistomal area to upper level of eyes, shining; strial punctures minute, as in male; interstrial scales about six times as long as wide.

Distribution.- Oaxaca.
MEXICO: Oaxaca: 11 km NE Tapanatepec, 9-VIl-53, S. L. Wood; 10 km W Zanatepec, 9-V11-53, S. L. Wood.

Biology.- Specimens were taken from phloem tissues of unthrifty twigs of a small, living Malvaceous tree.

Notes.- The above treatment was based on 10 paratypes.

## 57. Pseudothysanoes acaciae (Blackman)

 Fig. 144Cryptocleptes acaciae Blackman, 1943, Proc. U.S. Nat. Mus. 93:362 (Holotype, female; Brownsville, Texas; U.S. Nat. Mus., 56413)
Diagnosis.- This species is distinguished from subpilosus (Wood) by characters summarized in the above key.

Male.-Length 0.9-1.1 mm, 2.5 (female 2.7) times as long as wide; color dark reddish brown.

Frons as in yuccae (Wood) except more strongly, transversely impressed on lower half; more coarsely granulate above. Antenna and pronotum as in yuccae except asperities slightly smaller and more numerous; disc more nearly reticulate-granulate.

Elytra 1.6 times as long as wide; outline as in yuccae; striae not impressed, punctures very large, deep; interstriae half as wide as striae, smooth, punctures uniseriate, minute. Declivity rather steep, convex; strial punctures greatly reduced, obsolete on lower third; interstriae wider than striae, punctures minute, uniseriate. Vestiture of rows of minute strial hair and rows of erect interstrial scales; each scale about three to four times as long as wide, spaced within and between rows by distances greater than length of a scale.

Female.- Similar to male except more slender; frons broadly, very shallowly concave to vertex, smooth and shining, a few
minute punctures on upper half, almost glabrous; anterior margin of pronotum unarmed; strial punctures very small, distinct on disc, obsolete on declivity; interstrial scales very slightly more slender.

Distribution.-S Texas and Tamaulipas.
USA: Texas: Brownsville, Acacia beriandieri, H. S. Barber; Southmost, Cameron Co., 13-VI-53, Mimosa, S. L. Wood. MEXICO: Tamaulipas: Antiguo Morelos, 20-VI-53, 500 m , Mimosa, S. L. Wood; Llera, 15-VI-53, Mimosa, S. L. Wood.

Host.- Mimosa sp.
Biology.- Specimens were taken from phloem tissues of small branches.

Notes.- The above treatment was based on 29 specimens.

## 58. Pseudothysanoes subpilosus (Wood)

Cryptocleptes subpilosus Wood, 1956, Canadian Ent. 88:238 (Holotype, female; 32 km E Tehuantepec, Oaxaca, Mexico; Snow Ent. Mus., Univ, Kansas)
Diagnosis.- This species is distinguished from acaciae Wood by characters summarized in the above key.

Male.- Length $0.8-1.0 \mathrm{~mm}, 2.2$ (female 2.5) times as long as wide; color dark reddish brown.

Frons as in yuccae Wood except very slightly more nearly flattened, finely reti-culate-granulate, with a very shallow, narrow, median groove on lower half. Antenna and pronotum as in acaciae except anterior margin of pronotum armed by 8 to 10 teeth.

Elytra 1.3 times as long as wide; striae weakly impressed near declivity, punctures rather coarse, very deep; interstriae slightly narrower than striae, shining, fine punctures vulcanate on disc, granules as wide as interstriae, granules normal near declivity. Declivity steep, convex; striae not impressed on lower half, punctures decreasing in size and depth, very small near apex; interstrial granules decreasing in size, obsolete by middle of declivity, distinctly impressed punctures continue to apex. Vestiture of rows of minute strial hair and rows of interstrial scales; each scale about one and one-half times as long as wide, each slightly more than half as long as distance between scales within a row or between rows.

Female.- Similar to male except more slender; frons broadly, shallowly concave to vertex, smooth and shining below, a dense
patch of subpilose, coarse, short setae on upper half; anterior margin of pronotum unarmed; striae not impressed, punctures minute, rather shallow; interstriae almost smooth, subreticulate, punctures minute; declivital striae and interstriae as on dise; interstrial scales almost twice as long as wide.

Distribution.- Oaxaca.
MEXICO: Oaxaca: 32 km E Tehuantepec, 8-Vll-53, S. L. Wood.

Biology.- Specimens were taken from phloem tissues of cut branches of what presumably was Celtis iguanae.

Notes.- The above treatment was based on four paratypes.

## 59. Pseudothysanoes acares (Wood)

Cryptulocleptus acares Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):32 (Holotype, male: 30 km SE El Cameron, Oaxaca. Mexico: Wood Coll.)
Diagnosis.- This species is allied to mirus (Wood), but it may be distinguished by characters summarized in the above key.

Male. - Length $1.1-1.2 \mathrm{~mm}$ (female $1.3-1.4 \mathrm{~mm}$ ), 2.2 (female 2.7) times as long as wide; color yellowish brown, elytra darker.

Frons and pronotum as in mendicus, except posterior area of pronotum almost smooth and shining.

Elytra 1.3 times as long as wide, 1.5 times as long as pronotum; outline about as in mendicus; striae not impressed, punctures rather coarse; interstriae as wide as striae, punctures rather large, uniseriate. Declivity steep, convex; sculpture about as on disc except interstrial punctures closer. Vestiture consisting of minute strial hair and rows of erect interstrial scales; each scale two-thirds as long as distance between rows, similarly spaced within rows; each scale twice as long as wide.

Female.- Similar to female of mendicus except 2.7 times as long as wide; frons somewhat more deeply impressed, with a few minute granules in upper third of impression; strial and interstrial punctures closer and more distinct, general surface more irregular; declivity much more coarsely, deeply punctured; interstrial scales much closer, each four to six times as long as wide, very slightly longer.

Distribution.- Oaxaca.
MEXICO: Oaxaca: 30 km SE El Cameron, 21-VI-67. 1000 m, No. 80, S. L. Wood.

Brology. - Specimens were taken from phloem tissues of small branches of what appeared to be a leguminous tree.

Notes.- The above treatment was based on the type series of 27 specimens.

## 60. Pseudothysanoes mirus (Wood)

Cryptulocleptus mirus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. $10(2): 32$ (Holotype, male; 38 km S Matías Romero, Oaxaca, Mexico; wood Coll.)
Diagnosis.- This species is distinguished from acares Wood by the more deeply impressed upper areas of the female frons, by the more coarsely sculptured posterior areas of the pronotum, and by the much finer declivital punctures.

Male.- Length $1.0-1.1 \mathrm{~mm}$ (female $1.2-1.4 \mathrm{~mm}$ ), 2.2 (female 2.8) times as long as wide; color yellowish brown.

Frons similar to acares but more strongly convex. Pronotum as in acares except reticulation in posterior areas tending to be very slightly more rugose.

Elytra 1.3 times as long as wide, 1.4 times as long as pronotum; outline as in acares; striae not impressed, punctures rather coarse, more sharply impressed than in acares; interstriae irregular but much smoother than in acares, as wide as striae, punctures rather small and more widely spaced than in acares. Declivity steep, convex; surface smoother, punctures very slightly smaller than on disc. Vestiture as in acares except interstrial scales very slightly more widely spaced.

Female.- Similar to female of acares except 2.8 times as long as wide; frons more abruptly impressed at upper limits of concavity; posterior areas of pronotum more strongly reticulate; elytral surface less rugose; declivital punctures reduced to very fine strial and interstrial punctures; elytral scales similar, but less abundant.

Distribution.- Oaxaca.
MEXICO: Oaxaca: 38 km S Matías Romero, 24-VI-67, $250 \mathrm{~m}, \mathrm{No} .92$, S. L. Wood.

Brology.- Specimens were removed from phloem tissues of a shrub having a Mimosalike yellow flower.

Notes. - The above treatment was based on the type series of 42 specimens.

## 61. Pseudothysanoes aquilus (Wood)

Cryptulocleptus aquilus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. $10(2): 32$ (Holotype, male; 26 km E Morehia, Michoacán, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from mendicus (Wood) by the slightly larger size, by the darker color, by the much more broadly rounded anterior margin of the pronotum, by the much coarser male strial punctures, by the much more coarsely punctured female elytral declivity, and by the more extensive female frontal impression.

Male.- Length 1.1 mm (female 1.2-1.4 mm ), 2.3 (female 2.7) times as long as wide; color dark brown.

Frons and pronotum as in mendicus except anterior margin of pronotum much more broadly rounded, bearing eight teeth, and posterior area more clearly punctured.

Elytra 1.4 times as long as wide, 2.1 times as long as pronotum; outline as in mendicus; striae not impressed, punctures rather coarse, round, deep, interstriae as wide as striae, almost smooth, punctures minute, uniseriate. Declivity rather steep, convex; strial punctures decreasing rapidly in size, almost obsolete at apex; interstrial punctures minute. Vestiture consisting of fine, minute, strial hair and rows of erect interstrial scales; each scale almost as long as distance between rows, each about four times as long as wide.

Female.- Similar to male except 2.7 times as long as wide; frons shallowly concave from epistoma to vertex, smooth and shining on median half below, not specially ornamented by setae; anterior margin of pronotum unarmed; elytral surface more irregular, strial punctures smaller, but distinct; interstrial punctures minute, mostly obscure; declivity more irregular, more coarsely punctured much as acares (Wood); interstrial scales more closely placed.

Distribution.- Michoacán.
MEXICO: Michoacán: 26 km E Morelia, 14-VI-65, 2500 m , No. 56 , Acacia, S. L. Wood.

Biology.- Specimens were taken from phloem tissues of a recently broken branch of a small tree.

Notes.- The above treatment was based on the type series of 23 specimens.
62. Pseudothysanoes dislocatus (Blackman) Fig. 143

Cryptocleptes disloeatus Blackman. 1920, Mississippi Agric. Expt. Sta. Tech. Bull. 9:5l (Lectotype, female; Agricultural College, Mississippi: U.S. Nat. Mus., 24742, present designation)
Diagnosis. - This species may be distimguished from aquilus (Wood) by characters summarized in the above key.

Male.- Length $1.0-1.3 \mathrm{~mm}, 2.4$ (female 2.6) times as long as wide; color very dark reddish brown.

Frons convex, somewhat flattened on lower half, with an irregular median impression extending from upper level of eyes to level of antennal insertion, epistomal margin elevated; surface shining, finely reticulategranulate, a few rather coarse, shallow punctures; vestiture inconspicuous, sparse. Antennal scape elongate, slender; club small, oval. devoid of sutures.

Pronotum 0.91 times as long as wide; widest on basal third, sides rather evenly, convergently arcuate to rather broadly rounded anterior margin; anterior margin armed by four teeth; summit at middle, high; anterior slope coarsely, closely asperate; posterior area shining, subreticulate, a few minute punctures. Vestiture of sparse, short scales and hair.

Elytra 1.5 times as long as wide; sides almost straight and parallel on basal two-thirds, narrowly rounded behind; striae not impressed, punctures rather small, deep; interstriae almost smooth, as wide as striae, punctures very fine, uniseriate. Declivity convex, steep; strial punctures smaller than on disc; interstrial punctures very finely granulate. Vestiture of rows of minute, fine, short strial hair and rows of erect, interstrial scales; each scale about three to four times as long as wide, each slightly shorter than distance between scales within a row or between rows.

Female.-Similar to male except more slender; frons concave on median third to above upper level of eyes; scape ornamented by long hair; anterior margin of pronotum unarmed; strial punctures slightly smaller; interstrial scales slightly shorter.

Distribution. - West Virginia to Florida and Louisiana.

USA: Florida: Sebring, 20-VI-51, Hickory, S. L. Wood. Georgia: Brunswick, I2-V11-51, Hickory, S. L. Wood. Louisiana: Covington, 12-VI-51, Hickory, S. L. Wood.

Mississippi: Agricultural College. 10-1V, 6-22-V1-22; Electric Mills, 12-13-XI-19; Durant, 1-1II-20; Maxie, 24-X11-19, 23-V-20. Fort Adams, 30-X1I-19; Natchez, 16-11120, M. W. Blackman. North Carolina: Tryon. South Carolina: Charleston, 20-XI-04, W. F. Fiske. West Virginia: Morgantown, 6-X1-1898.

Host.- Carya spp.
Biology. - This bigamous species constructs longitudinal, biramous parental galleries in the cambium region of small, recently cut, or dying twigs or branches. Egg galleries are packed with frass as the female progresses; the male usually dies at the entrance hole or in the nuptial chamber. According to Blackman (1922:74) the eggs are not placed in niches, but are packed in frass along the edge of the tunnel. Each female produces 12 to 53 eggs, or an average of 29.6. Larval mines are long and irregular.

Notes.- The above treatment was based on 159 specimens, including the type series. Blackman neglected to designate a type, although he labeled a female holotype. That female is here designated as the lectotype of dislocatus Blackman.

## 63. Pseudothysanoes perseae Wood

Pseudothysanoes perseae Wood, 1981, Great Basin Nat. 41:125 (Holotype, male; Cerro Chipinque. Monterrey, Nuevo León, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from dislocatus (Blackman) by the more slender body, by the more distinct strial punctures on the disc, by the longer more slender elytral scales, and by other characters described below.

Male.- Length 1.0 mm (female 1.2 mm ), 2.4 (female 2.7) times as long as wide; color brown.

Frons more broadly, evenly convex than in dislocatus, fovea similar. Antenna as in dislocatus.

Pronotum as in dislocatus except more slender and scales stouter.

Elytra more slender than in dislocatus, discal punctures more clearly impressed, declivity steeper, declivital punctures not deeper but more clearly formed, interstrial scales distinctly longer, each six to eight times as long as wide.
Female.- Similar to male except much more slender; frons moderately, concavely impressed to upper level of eyes (stronger and more extensive than in dislocatus) and
foveate at center, without setal ornamentation; scape with a tuft of long hair; anterior margin of pronotum unarmed; interstrial setae more slender, each at least eight times as long as wide.

Distribution.- Nuevo León.
MEXICO: Nuevo León: Cerro Chipinque, Monterrey, $31-\mathrm{I}-80,1350 \mathrm{~m}, \mathrm{No}$. S-021, Persea, T. H. Atkinson.

Notes.- The above treatment was based on the type series of five specimens.

## 64. Pseudothysanoes huachucae Blackman Fig. 144

Pseudothysanoes huachucae Blackman, 1943, Proc. U.S. Nat. Mus. 93:355 (Holotype, male; Huachuca Mts., Arizona; U.S. Nat. Mus., 56407, presumably lost)
Diagnosis.- This species appears to fit this species group rather well, near dislocatus Blackman, except that the antennal club has two well-defined sutures. Refer to the key for other characters that distinguish these species.

Male.- Length $1.0-1.4 \mathrm{~mm}, 2.3$ (female 2.7) times as long as wide; color very dark brown.

Frons as in dislocatus except slightly more extensively impressed. Antennal club elon-gate-oval, sutures 1 and 2 clearly indicated both by grooves and rows of setae. Pronotum as in dislocatus except anterior margin armed by six teeth.

Elytra as in dislocatus except declivity not quite as steep or as narrowly convex; declivital striae almost obsolete, strial and interstrial punctures not clearly evident; interstrial scales slightly longer and wider, about four times as long as wide, not present on central part of declivity.

Female- Similar to male except more slender; frons about as in male but more strongly impressed; anterior margin of pronotum unarmed; strial punctures slightly smaller, not as deep, reduced but present on declivity; interstrial scales slightly shorter and narrower, not absent on central part of declivity.

Distribution.- Arizona.
USA: Arizona: Miller Canyon, Huachuca Mts., 25-VI07, H. A. Kaeber; "Palmerlee," $15-\mathrm{V} 11$, H. A. Wenzel.

Notes. - The above treatment was based on seven paratypes and on my male homotype and a female, both labeled Palmerlee, Arizona. At some time between 1952 and

1961 the holotype was dislodged from its pin and was remounted; between 1961 and 1971 it was again dislodged from its pin and lost. Seven paratypes bearing data identical to that of the type remain in the U.S. National Museum.

## 65. Pseudothysanoes mendicus (Wood)

Cryptulocleptus mendicus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. $10(2): 31$ (Holotype, male; II km S Colima, Colima, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from pumilus Wood by the smoother elytral surface, by the much more slender elytral scales, and, in the female, by the less strongly concave frons that is devoid of special setal ornamentation.

Male.- Length $0.9-1.0 \mathrm{~mm}$ (female 1.1-1.3 mm), 2.4 (female 2.9) times as long as wide; color yellowish brown, some specimens darker.

Frons as in pumilus; pronotum also as in pumilus except six teeth on anterior margin larger, posterior area more finely reticulate.

Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, narrowly rounded behind; striae not impressed, fine punctures spaced by two diameters of a puncture; interstriae shining, marked by irregular lines, twice as wide as striae, punctures distinctly smaller than those of striae. Declivity rather steep, convex; essentially as on disc except punctures much smaller. Vestiture consisting of very minute strial hair and rows of erect interstrial scales; each scale three times as long as strial hair, slightly shorter than distance between rows of scales, each about three times as long as wide.

Female.- Similar to male except 2.9 times as long as wide; frons concave on median two-thirds to upper level of eyes, not especially ornamented by setae; scape bearing a small tuft of long hair; anterior margin of pronotum unarmed; elytral punctures much more obscure; elytral scales more slender, each about six times as long as wide.

Distribution.-Colima.
MEXICO: Colima: 53 km S Colima, 27-VI-65, 700 m , No. 122, S. L. Wood.

Biology.- Specimens were taken from phloem tissues of a broken branch of a shrubby, leguminous desert tree.

Notes.- The above treatment was based on the type series of 58 specimens.

## 66. Pseudothysanoes pumilus (Wood)

Cryptulocleptus pumilus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. $10(2): 31$ (Holotype, male; 53 km S Colima, Colima, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from mendicus (Wood) by characters summarized in the above key.

Male. - Length $0.8-0.9 \mathrm{~mm}$ (females $1.0-1.1 \mathrm{~mm}$ ), 2.3 (female 2.5) times as long as wide; color yellowish brown.

Frons convex, narrowly, transversely impressed just above epistomal margin, more strongly in median area; surface shining, rather coarsely reticulate; vestiture confined to epistomal margin. Antennal club rather narrowly ovate; devoid of sutures.

Pronotum 0.90 times as long as wide; widest a third pronotum length from base, sides evenly arcuate to rather broadly rounded anterior margin; anterior margin armed by four small teeth; summit just behind middle, rather well developed asperities on anterior slope coarse; posterior area shining, minutely rugulose-reticulate, fine punctures obscure; vestiture largely scalelike.

Elytra 1.4 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, punctures very small but distinct; interstriae somewhat irregular, shining, twice as wide as striae, squamiferous punctures equal in size to those of striae but more widely spaced. Declivity rather steep, convex; sculpture as on dise but all punctures very slightly smaller. Vestiture consisting of minute, fine strial hair and rows of erect interstrial scales; each scale twice as long as strial hair, almost as long as distance between rows, about twice as long as wide, strongly tapered toward their bases.

Female.- Similar to male except 2.5 times as long as wide; frons rather deeply concave on median two-thirds to well above eyes, with a row of stout, subplumose setae on upper margin; scape bearing a small tuft of long hair; anterior margin of pronotum unarmed; strial punctures equal in size but less distinct; elytral scales three times as long as wide.

Distribution.- Colima.
MEXICO: Colima: 53 km S Colima, 27-V1-65, 700 m , No. 122, S. L. Wood.

Biology.- Specimens were taken from phloem tissues of an unidentified desert shrub.

Notes.- The above treatment was based on the type series of 58 specimens.

## Genus Stenocleptus Blackman

Stenocleptus Blackman, 1943, Proc. U.S. Nat. Mus. 94(3165):356 (Type-species: Stenocleptus rhois Blackman $=$ Pseudothysanoes suleatus Bruck, original designation)
Diagnosis.- This genus is closely related to Pseudothysanoes Blackman, subgenus Aphanocleptus Wood, and eventually may have to be united with that group. It shares many of the Pseudothysanoes characters and has the short, somewhat flattened antennal scape and similar antennal club of Aphanocleptus, but the elytral declivity is subvertical on the lower two-thirds and rather strongly bisulcate with a rather strong, irregular impression on the lower half.

Description.- Length $1.0-1.5 \mathrm{~mm}, 2.5$ times as long as wide; color brown to black, vestiture pale.

Frons sexually dimorphic, flattened to shallowly concave, impression strongest in female. Antennal scape short, flattened or not, little if any longer than pedicel; funicle 6 segmented; club small, widest near base, with two straight sutures clearly indicated. Pronotum as wide as long; asperate on anterior half; anterior margin unarmed, occasional submarginal serrations present. Elytra usually covered by an incrustation, sculpture on disc conservative; declivity subvertical, bisulcate, not sexually dimorphic.

Distribution.-California and Puebla.
Biology.- The one species taken in the field by me, ruficollis Wood, was bigamous and constructed transverse, biramose parental galleries in the cambium region of small branches.

Notes.- This genus is doubtfully distinct from the subgenus Aphanocleptus of Pseudothysanoes. In the absence of any intermediacy between these groups in the species presently available for study, Stenocleptus is retained as a distinct genus.

## Key to the Species of Stenocleptus

1. Elytral vestiture consisting of rather coarse, pointed bristles; antennal scape longer than wide, feebly if at all flattened; female frons flat; mature color of pronotum black; S California; Ceanothus and Rhus; 1.2-1.5 mm
2. sulcatus (Bruck)

- Elytral vestiture of flattened, subtruncate scales; antennal scape flattened in both sexes, very broad in female; female frons moderately concave; mature color of pronotum reddish brown; Puebla; $1.0-1.3 \mathrm{~mm}$

2. ruficollis Wood

## 1. Stenocleptus sulcatus (Bruck) Fig. 147

Pseudothysanoes sulcatus Bruck, 1936, Bull. S. California Acad. Sci. 35:33 (Holotype, male; Mt. Wilson, Los Angeles Co., California; Ohio State Univ. Coll.)
Stenocleptus sulcatus; Wood, 1956, Canadian Ent. 88:240
Stenocleptus ceanothi Blackman, 1943, Proc. U.S. Nat. Mus. 93:358 (Holotype, female; Yosemite N.P., California; U.S. Nat. Mus.); Bright, 1966, Pan Pacific Ent. 42:305. Synonymy
Stenocleptus rhois Blackinan, 1943, Proc. U.S. Nat. Mus. 93:357 (Holotype, female; Orange, Orange Co., California; U.S. Nat. Mus.): Wood, 1973, Great Basin Nat. 33:186. Synonymy
Diagnosis.- This species is much more likely to be confused with species of Pseudothysanoes or with females of some species of Cactopinus than it is with ruficollis Wood, the only other representative of the genus recognized here. The confusion results from the similar size and color and elytral incrustations rather than from true relationship. The very short, antennal scape, together with the subvertical, sulcate elytral declivity, serve to distinguish it.

Male.- Length $1.2-1.5 \mathrm{~mm}, 2.5$ times as long as wide; color black, usually covered by an incrustation.

Frons transversely impressed above epistoma, flattened to weakly convex above; surface finely sculptured, largely obscured by abundant, coarse, subplumose, moderately long setae. Antennal scape short, slender, slightly longer than pedicel; club small, more than one and one-half times as long as wide, two straight sutures conspicuously marked.

Pronotum 0.90 times as long as wide; subcircular in outline; summit at center, rather high, asperities comparatively few in number except at summit; anterior margin usually armed medially by two submarginal teeth; surface of disc (usually encrusted), when
visible, shining and obscurely subreticulate, punctures rather small, sparse.

Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on more than basal two-thirds, very broadly, irregularly rounded behind; surface usually encrusted; striae not impressed, punctures small, shallow, distinct; interstriae shining, almost twice as wide as striae, punctures not visible in specimens examined. Declivity confined to less than posterior fourth, vertical on more than lower half; narrowly, rather deeply bisulcate; surface irregular, strial punctures indistinctly impressed. Vestiture of sparse, short, stout interstrial bristles.

Female.- Similar to male except antennal scape ornamented by about twice as many hairlike setae.

Distribution. - S California.
USA: California: Big Pine Park, 13-IV-35, Cecrocarpus ledifolius; 1 mile S Pinyon Flats, San Bernardino N.F., 6-V1-59, Rhus laurina, R. W. Stark; La Crescenta, 1-I-35, Ceanothus divaricatus C. R. Bruck; Mt. Wilson, Los Angeles Co., 13-I-34, Ceanothus integerrimus, C. R. Bruck; San Diego Co., 17-XII-90; 4 miles NW Jacumba, San Diego Co., 25-VIII-68, D. E. Bright; Orange, 24-X-34, Rhus integrifolia, W. Ebling; Yosemite, 28-II-34, $3800-4000 \mathrm{ft}$, C. integerrimus, D. DeLeon.

Hosts.- Ceanothus integerrimus, Rhus laurina.

Biology.- This species was taken from phloem tissues of small branches.

Notes. - The above treatment was based on the holotype, allotype, and 55 paratypes of sulcatus, on the type series of ceanothi and rhois, and on 180 other specimens.

## 2. Stenocleptus ruficollis Wood

Stenocleptus ruficollis Wood. 1956, Canadian Ent. 88:239 (Holotype, female; 20 km SE Matamoros. Puebla, Mexico; Snow Ent. Mus., Univ. Kansas)
Diagnosis. - This species may be distinguished from sulcatus (Bruck) by characters summarized in the above key.

Male.- Length $1.0-1.3 \mathrm{~mm}, 2.4$ times as long as wide; color of pronotum reddish brown, elytra black.

Frons transversely impressed above epistoma, subconcave at center, convex above; surface rather coarsely granulate-punctate; vestiture rather sparse, coarse, short. Antennal scape short, as wide as long, club moderately small, less than one and one-half times as long as wide, with two conspicuously marked sutures.

Pronotum 0.97 times as long as wide; essentially as in sulcatus except some setae on dise scalelike.

Elytra 1.4 times as long as wide; general features as in sulcatus except strial punctures larger, equal in width to interstriae, declivity more broadly impressed on lower half; interstrial bristles much stouter, slightly flattened.

Female.- Similar to male except frons shallowly, broadly concave, with more abundant frontal vestiture; antennal scape ornamented by a much larger tuft of hair.

Distribution.- Puebla.
MESICO: Puebla: 20 km SE Matamoros, 3-VII-53, $1200 \mathrm{~m}, \mathrm{~S}$. L. Wood.

Biology.- Specimens were taken from phloem tissues of unthrifty twigs of a large, living tree.

Notes.- The above treatment was based on 65 paratypes.

## Genus Thy'sanoes LeConte

Thysanoes LeConte, 1876, Proc. American Philos. Soc. 15:369 (Type-species: Thysanoes fimbricomis LeConte, monobasic)
Diagnosis.- This genus is allied to Pseudothysanoes Blackman, but it is distinguished by the pronotum being longer than wide, by the presence of antennal sutures in all
species, by the much broader protibiae, and by the xylophagous habit.

Description.- Length $1.2-2.3 \mathrm{~mm}$, females 2.6-3.0 and males 2.3-2.7 times as long as wide; color pale yellowish brown to almost black.

Frons sexually dimorphic, convex to weakly impressed on lower half in males, flattened to deeply, extensively, concavely impressed in females, rarely ornamented by hair. Antennal scape elongate, ornamented by sparse to abundant long hair; funicle six-segmented; club moderately large, distinctly constricted at suture 1 , often also at 2 , both sutures procurved, 2 much more strongly arched. Pronotum asperate on anterior half, anterior margin armed in male. Elytra conservatively sculptured, striate with strial hair and uniseriate rows of erect interstrial scales. Protibiae rectangularly flattened, rather broad, much as in Micracis.

Distribution.- E Canada to Costa Rica; 13 species are known.

Biology.-All species apparently are bigamous, xylophagous, and construct a parental gallery system essentially as in Micracis and Hylocurus, having a central nuptial chamber with two extensions extending in opposite directions with the grain of the wood for a few millimeters, then each branching into two egg galleries. Larval mines usually are rather long and tend to follow the grain of the wood. They normally infest material about 2 to 6 cm in diameter; light colored, dense woods evidently are preferred.

Notes.- Species in this genus exhibit very minor variations from one another and, consequently, are very difficult to classify either anatomically or biologically.

## Key to the Species of Thysanoes

1. Female frons rather weakly impressed, upper limits of impressed or excavated area ending well below upper level of eyes, convex above impressed area; interstrial granules on disc absent in both sexes (weakly developed in some females)

- Female frons more strongly, extensively impressed, excavation or flattened continuation of it extending well above upper level of eyes; interstrial granules on disc well developed except in epicaris and female fimbricormis 5

2(1). Female frontal excavation flattened or feebly concave on lower half, a strong median fovea invading convex area at middle of frons; male frons mostly convex; pronotal disc almost smooth, shining; body color rather light yellowish brown; Louisiana and Florida to Veracruz; Quercus, Carya; 1.3-1.5 mm

- Female frons convex on lower two-thirds, fovea at fundus of excavation; male frontal excavation less well developed, occupying lower half of frons; pronotal disc strongly reticulate, subshining; body color dark brown; larger species
3(2). Scales on elytral declivity spaced within a row and between rows by distances about one and one-half times length of a scale; strial and interstrial punctures rather shallow, interstrial granules on declivity fine; female frons almost glabrous; Aguascalientes to Jalisco; Canavelia, etc.; $1.4-1.7 \mathrm{~mm}$

2. inornatus Wood

- Scales on elytral declivity spaced within a row or between rows by distances equal to or less than length of a scale; strial and interstrial punctures very slightly deeper, interstrial granules on declivity moderately coarse .4

4(3). Female frons smooth and polished almost to upper level of eyes, vertex ornamented by only a few scattered setae; declivital granules fine, strial punctures reduced, almost obsolete in male; New Mexico; Berberus; 1.6-2.0 mm
3. berbericolens Wood

- Female frons reticulate on upper two-thirds, vertex ornamented by rather abundant short setae; declivital granules rather coarse, strial punctures rather coarse, distinctly impressed; Hidalgo to Oaxaca; shrubs; $1.5-1.8 \mathrm{~mm}$

4. mexicanus Wood

5(1). Female frontal concave area entirely devoid of a median carina or tubercle on $\quad$ upper half ................................................................................................................. 6

- Female frons with a median carina or tubercle at upper level of eyes (very weakly developed in texanus); striae about as wide as interstriae

6(5). Strial punctures reduced but visible on declivity, interstrial granules either
present or absent in female, always present on male interstriae 1 ..... 7

- Strial punctures obsolete on declivity, interstrial granules always present except obsolete on lower half of 1 in male
7(6). Interstrial scales on declivity four to eight times as long as wide in both sexes; interstrial granules on disc extend to base in both sexes; female frontal excavation not extending above upper level of eyes
- Interstrial scales on declivity not more than four times as long as wide (except some specimens of fimbricornis); interstrial granules on disc absent in female, rarely attain base in male; female frontal excavation more extensive above
8(7). Smaller; discal interstrial granules moderately large, little if any larger on declivity of male; male interstrial scales about as long as distance between rows; Virginia to Florida and Texas; $1.5-1.7 \mathrm{~mm}$
- Larger; discal interstrial granules minute, those on declivity very coarse, their diameters as great as that of strial punctures, each as high as wide; interstrial scales on declivity one to one and one-half times as long as distance between rows; Chiapas; 2.3 mm (see also 7. tuberculatus Wood)

6. granulifer Wood
$9(7)$. Female frons conspicuously reticulate, dull from epistomal margin to vertex; strial punctures on disc coarser, deeper; interstriae on male disc devoid of granules; Jalisco; 1.8-2.2 mm
7. epicaris Wood

- Female frons smooth, polished from epistomal margin to level of antennal insertion, reticulate above; strial punctures on disc small, shallow, interstriae on male disc with fine, uniseriate granules
10(9). Body color dark reddish brown; strial punctures and interstrial granules on disc slightly larger and deeper; declivital scales broader toward base; tuft of hair on female scape large; Costa Rica; Calliandra confusa; 1.5-2.2 mm

9. neotropicalis Wood

- Body color pale yellowish brown (Florida and Mexican specimens darker); strial punctures and interstrial granules on disc finer; declivital scales averaging much more slender; tuft of hair on female scape larger; Illinois, Pennsylvania, and Florida to Hidalgo and Durango; $1.4-2.1 \mathrm{~mm}$

## 10. fimbricornis LeConte

11(6). Interstrial granules on male declivity rather small, close except decreasing in size on 1 , becoming obsolete on lower half, strial punctures replaced by minute granules on upper half of declivity, becoming obsolete below; scales on male declivity six to eight times as long as wide; Michoacán; Quercus; 1.4-2.0 mm ... 11. adonis Wood

- Interstrial granules on male declivity rather coarse except absent on 1, striae unmarked by granules; subsulcate between male interstriae 2 and suture on declivity; scales on male declivity large, about six times as long as wide; Hidalgo; Quercus; 1.9-2.3 mm

12. subsucatus Wood

12(5). Smaller; female frons subglabrous, median carina very weakly developed; strial punctures on declivity moderately coarse, deeply impressed; Texas to Colima and Veracruz; Prosopis, etc.; $1.2-1.5 \mathrm{~mm}$ 13. texanus Blackman

- Larger; female frons with median carina well developed at upper level of eyes; strial punctures reduced in size, shallow, obscure, almost obsolete 13
13(12). Interstrial scales rather small, slender, each scale about four times as long as wide; female frontal carina long, gradually elevated, rather low; color reddish brown; Georgia and Florida to Louisiana (and Oaxaca?); Quercus, etc.; 1.4-1.7 mm .

14. lobdelli Blackman

Interstrial scales short, broad, each scale about twice as long as wide or less; female frontal carina short, rather high, abrupt; color almost black; Arizona and New Mexico to Durango; Quercus; 1.8-2.2 mm
15. xylophagus Blackman

## 1. Thysanoes pallens Wood

Thysanoes pallens Wood, 1956, Canadian Ent. 88:234 (Holotype, female; Sanford, Florida; Snow Ent. Mus., Univ. Kansas)
Diagnosis.- This is the most distinctive species in the genus, although both sexes superficially resemble males of fimbricornis LeConte. It is distinguished by the pale yellowish brown color, by the shallowly, less extensively impressed female frons, with a conspicuous central fovea, and by the simple sculpture and vestiture.

Female.- Length $1.3-1.5 \mathrm{~mm}, 2.9$ (male 2.7) times as long as wide; color pale yellowish brown to light brown.

Frons rather strongly convex on upper half, rather weakly impressed below, not concave, with a large, impressed, central fovea; upper area minutely granulate with a few larger granules intermixed, becoming almost reticulate below except smooth and shining on median line from fovea to epistoma; vestiture sparse, inconspicuous. Antennal scape ornamented by a few long hairlike setae.

Pronotum 1.06 times as long as wide; somewhat subquadrate, all margins moderately arcuate, widest just behind middle; anterior margin unarmed; summit slightly in front of middle; anterior slope moderately asperate; posterior area shining, subreticulate,
a few small punctures, those behind summit very feebly granulate. Vestiture sparse, of stout, delicate setae.

Elytra 1.8 times as long as wide, 1.8 times as long as pronotum; sides almost straight and parallel on basal three-fourths, rather broadly rounded behind; striae not impressed, punctures rather small, shallow; interstriae almost smooth to subreticulate, about as wide as striae; punctures fine, uniseriate, becoming finely granulate toward declivity. Declivity very steep, convex; striae very weakly impressed; interstrial granules slightly larger. Vestiture of rows of minute, very fine strial hair, and rows of erect interstrial scales; each scale about four to six times as long as wide, spaced within and between rows by distances about equal to length of a scale.

Male. - Similar to female except very slightly stouter; frons more coarsely sculptured, impression slightly less extensive; anterior margin of pronotum more strongly arcuate, armed by six small teeth; interstrial granules extend to basal fourth; interstrial scales three to five times as long as wide.

Distribution.- Louisiana and Florida to Veracruz.

USA: Florida: Dade City, 18-VI-51, Rhizophora mangle, S. L. Wood. Sanford, 11-VII-51, Quereus, S. L. Wood; Suanee Springs, 15-VI-51, Pecan, S. L. Wood; Oleno St. Pk., 16-VI-51, Carya, S. L. Wood. Louisiana: Madisonville, I1-VI-51, Qucreus. S. L. Wood. MESICO: San Luis Potosí: Pujal, 20-VI-53, S. L. Wood. Veraeruz: Lago Catemaco, 5-V-69, D. E. Bright.

Hosts.- Carya spp., Quercus spp., Rhizophora mangle.

Bıology.- As described for the genus.
Notes. - The above treatment was based on 22 paratypes.

## 2. Thysanoes inornatus Wood

Thysanoes inornatus Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):24 (Holotype, female; Volcán Colima, Jalisco, Mexico)
Diagnosis.- This species is distinguished from the closely allied mexicanus Wood by the greatly reduced strial punctures on the declivity, by the shorter, more widely spaced interstrial scales, by the finer interstrial granules on the declivity, and by the almost glabrous female frons.

Female.- Length $1.4-1.7 \mathrm{~mm}, 2.7$ (male 2.3) times as long as wide; color very dark brown.

Frons moderately, rather broadly concave from epistoma to upper level of eyes; surface above concavity reticulate-granulate, becoming reticulate on upper part of concavity, smooth and shining over lower areas; a fovea at center; almost glabrous except near lateral margins of epistoma. Antennal scape bearing numerous long setae.

Pronotum 1.04 times as long as wide; widest one-third length from base, sides arcuate, not converging on basal half, rather strongly constricted in front of middle, moderately rounded in front; anterior margin armed by six teeth; summit at middle; posterior area reticulate to obscurely rugose-reticulate, a few minute, obscure punctures. Vestiture sparse, consisting of a few short, stout setae.

Elytra 1.6 times as long as wide; sides almost straight and parallel on basal threefourths, rather narrowly rounded behind; striae not impressed, punctures small, shallow; interstriae almost smooth, with obscure lines, almost three times as wide as striae, punctures sparse, uniseriate, very finely granulate. Declivity steep, convex; strial punctures reduced, minute to obsolete; interstrial granules regularly spaced, fine. Vestiture of rows of very minute, fine, strial hair, and rows of erect interstrial scales; each scale three to four times as long as wide, spaced within a row by one and one-half to three times length of a scale, between rows by about one and one-half to three times length of a scale.

Male.-Similar to female except stouter, 2.3 times as long as wide; frontal impression smaller, about two-thirds as large, reticulation extending almost to epistomal area; scape sparsely pubescent; teeth on anterior margin of pronotum larger; interstrial scales wider, each two to three times as long as wide.

Distribution. - Aguascalientes to Jalisco.
MEXICO: Aguascalientes: Aguascalientes, 12-V1-65, 2100 m , Mimosa, S. L. Wood. Jahisco: Volcán Colima, 23-VI-65, 2500 m , No. 103, unknown shrub, and No. 106, Rhus, S. L. Wood.

Hosts.-Mimosa sp., Rhus sp.
Biology. - As described for the genus.
Notes. - The above treatment was based on the type series of 25 specimens. The series of males from Aguascalientes was somewhat
more variable than those from Jalisco; in some the interstrial scales were as slender as in the females from Jalisco.

## 3. Thysanoes berbericolens Wood

Thysanoes berbericolens Wood, 1971. Great Basin Nat. 31:73 (Holotype, female: Nogal Lake, Lincoln Co., New Mexico: Wood Coll.)
Diagnosis.- This species is distinguished from the closely related inornatus Wood by the more extensively impressed female frons that is smooth and polished to above the upper level of the eyes, by the unarmed anterior margin of the female pronotum, by the absence of interstrial granules on the disc, and by the more closely spaced interstrial scales.

Female.- Length 1.6-2.0 mm, 2.6 times as long as wide; color dark brown.

Frons shallowly concave from epistoma to slightly above eyes, upper fourth minutely punctured, smooth and shining, obscurely foveate at center. Scape as in inornatus.

Pronotum 0.96 times as long as wide; as in inornatus except very broadly rounded in front; and posterior area obscurely, finely reticulate.

Elytra 1.7 times as long as wide, 1.9 times as long as pronotum; outline as in ornatus; striae not impressed, punctures rather small, impressed; interstriae twice as wide as striae, punctures fine, uniseriate, not at all granulate except at base of declivity. Declivity steep, convex; strial punctures minute to obsolete; interstrial punctures finely granulate. Vestiture of rows of fine strial hair, and interstrial rows of erect scales; each scale four to five times as long as wide; spaced within and between rows by distances equal to length of a scale.
Male.-Similar to female except frontal impression not as deep or as extensive; anterior margin of pronotum armed by six teeth; declivital strial punctures completely obsolete; interstrial scales slightly shorter, each about four times as long as wide.

## Distribution.- New Mexico.

USA: New Mexico: 16 km ( 10 miles) SE Bingham, No. 28, and Nogal Lake, Lincoln Co., No. 30, 1-V1-69, 2300 m, Berberus fremontii, S. L. Wood.

Host.- Berberus fremontii.
Biology.- As described for the genus.

Notes.- The above treatment was based on the type series of 27 specimens.

## 4. Thysanoes mexicanus Wood

Thysanoes mexicanus Wood, 1956, Canadian Ent. 88:234 (Holotype, female: 40 km SE Oaxaca, Oaxaca, Mexico: Snow Ent. Mus., Univ, Kansas)
Diagnosis.- This species is distinguished from berbericolens Wood by the slightly less extensive frontal impression, with the surface of the upper area more coarsely sculptured and pubescent, and by the larger punctures on the declivital striae.

Female.- Length $1.5-1.8 \mathrm{~mm}, 2.9$ times as long as wide; color dark brown.

Frons as in inornatus Wood except upper area more coarsely granulate and pubescence on vertex, longer and more abundant, a moderately large tuft of hair on antennal scape. Pronotum 1.0 times as long as wide, otherwise as in berbricolens.

Elytra as in berbericolens except discal strial punctures deeper, declivital strial punctures less strongly reduced, and interstrial granules very slightly larger; vestiture identical.

Male.-As in male berbericolens except 2.6 times as long as wide; strial punctures on disc deeper, interstrial punctures larger; punctures of declivital striae reduced but visible; declivital scales as long as those of female, each three to four times as long as wide.

Distribution.- Hidalgo to Oaxaca.
MEXICO: Hidalgo: 26 km N Ixmiquilpan, 10-V11-67, 1900 m , Nos. 187, 188, Acacia, S. L. Wood. Oaxaca: 40 km SE Oaxaca, 6-V11-53, shrub branches, S. L. Wood; 184 km S Oaxaca on Highway 131, 27-30-V-71, 2000 m , mistletoe on alder, D. E. Bright.

Hosts.- Acacia sp. and other shrubs.
Biology.- As described for the genus.
Notes.- The above treatment was based on 20 paratypes and on three other specimens.

## 5. Thysanoes berchemiae Blackman Fig. 143

Thysanoes berschemiae Blackman, 1920, Mississippi Agric. Expt. Sta. Tech. Bull. 9:44 (Lectotype, female; Vicksburg, Mississippi; U.S. Nat. Mus., 24738, present designation)
Thysanoes berchemiae Blackman, 1922, Mississippi Agric. Expt. Sta. Tech. Bull. 11:73 (emendation)

Diagnosis.- This species is distinguished from the allied epicharis Wood by the small, shining, impressed area just below the female central frontal fovea; interstrial punctures more coarsely granulate; all surfaces more brightly shining; elytral scales much more slender.

Female.- Length $1.5-1.7 \mathrm{~mm}, 2.8$ times as long as wide; color very dark reddish brown.

Frons shallowly concave from epistoma to slightly above upper level of eyes; surface finely reticulate-granulate above, becoming reticulate below except smooth and brightly shining in median area from epistoma to central fovea, part of this area near fovea weakly impressed. Antennal scape ornamented by more than a dozen long, hairlike setae.

Pronotum 1.1 times as long as wide; widest near middle; sides very weakly arcuate on posterior two-thirds, almost parallel, very broadly rounded in front; anterior margin unarmed; summit in front of middle, moderately high; anterior area asperate; reticulate behind, with a few small, shallow punctures. Vestiture very sparse, of short, stout setae.

Elytra 1.8 times as long as wide; outline as in inornatus; striae not impressed, punctures small, moderately deep; interstriae shining, two to three times as wide as striae, punctures rather coarsely granulate. Declivity steep, convex; strial punctures slightly reduced in size, not as deep as on disc; interstrial granules slightly higher. Vestiture of rows of minute strial hair and rows of erect interstrial scales; each scale six to eight times as long as wide, each very slightly longer than distance between scales within a row and between rows.

Male.-Similar to female except stouter, 2.6 times as long as wide; frontal impression confined to lower half, upper area more coarsely granulate; anterior margin of pronotum armed by six small teeth; interstrial granules slightly larger; interstrial scales four to six times as long as wide.

Distribution.-Virginia to Florida and Texas.

USA: Florida: Dade City, East River, Snead. Louisiana: Greenwell Springs. Mississippi: Agricultural College, Durant, Vicksburg. Texas: Victoria. Virginia: Len Haver, Princess Ampe.

Hosts.-Berchemia scandens, Quercus sp., Ulmus sp.

Biology.- As described for the genus.
Notes.- The above treatment was based on the type series of 20 specimens and on 57 other specimens. In the original publication Blackman misspelled the generic name of the host on which this name was based. He made the correction in 1922; the amended spelling should be continued as the correct name for this species. The female syntype from Vicksburg that has been labeled as the type is here designated the lectotype of this species.

## 6. Thysanoes granulifer Wood

Thysanoes granulifer Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):15 (Holotype, male; San Cristobal de las Casas, Chiapas, Mexico; Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from berchemiae Blackman by the larger size, by the smaller discal interstrial tubercles, by the much larger declivital interstrial tubercles, and by the much larger declivital scales.

Male.- Length $2.3 \mathrm{~mm}, 2.9$ times as long as wide; color dark reddish brown.

Frons on holotype largely concealed by pronotum, evidently as in berchemiae. Pronotum as in berchemiae.

Elytra 1.8 times as long as wide; outline as in berchemiae; striae not impressed, punctures moderately coarse, deep; interstriae smooth, shining, slightly narrower than striae, punctures fine, slightly granulate, uniseriate, granules coarse near declivity. Declivity steep, convex; strial punctures slightly smaller than on disc, deep; interstrial tubercles as wide as diameter of a strial puncture, as high as wide on interstriae 1-7, very slightly smaller on lower half of declivity. Vestiture of rows of minute, fine strial hair, and rows of erect interstrial scales; scales on disc about three times as long as wide, shorter than distance between rows, on declivity four to eight times as long as wide, one to one and one-half times as long as distance between rows.

Distribution.- Chiapas.
MEXICO: Chiapas: San Cristobal de las Casas, 7-V69, J. E. H. Martin.

Notes.- The above treatment was based on the holotype.

## 7. Thysanoes tuberculatus Wood

Thysanoes tuberculatus Wood, 1975, Great Basin Nat. 35:29 (Holotype, male; 85 km or 5.3 miles $S$ Valle Nacional, Oaxaca, Mexico; Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from granulifer Wood by the smaller size and by the very different elytral declivity as described below.

Male.- Length $1.8 \mathrm{~mm}, 2.7$ times as long as wide; color rather dark yellowish brown.

Frons and pronotum as in granulifer and berchemiae Blackman.

Elytra 1.6 times as long as wide; disc as in granulifer except granules slightly larger. Declivity steep, convex; striae 1 and 2 with punctures minute, visible almost to apex; suture slightly elevated, with a row of small granules on basal half; interstriae 2 with two or three tubercles on less than basal fourth, broadly impressed below and entirely devoid of punctures and granules; interstriae 3 moderately elevated on middle third and armed with a row of six to eight rather coarse tubercles, lower third without punctures or granules; lateral interstriae each with a row of tubercles on basal area but none of them attaining normal apex for these interstriae. Vestiture of rows of interstrial scales, scales on disc largely abraded, little if any longer than wide, longer at base of declivity; those on 3 up to three times as long as on disc and four times as long as wide, slightly shorter on other interstriae; declivital interstriae 2, 4, lower two-thirds of 1 , and lower half of 3 glabrous.

## Distribution.- Oaxaca.

MEXICO: Oaxaca: 85 km or 53 miles $S$ Valle Nacional, 24-V-71, 3300 m , D. E. Bright.

Notes.- The above treatment was based on the holotype.

## 8. Thysanoes epicaris Wood

Thysanoes epicaris Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):35 (Holotype, female; 39 km S Mazamitla, Jalisco, Mexico; Wood Coll.) Diagnosis.- This species is allied to fimbricornis LeConte, but it is distinguished by the less deeply impressed, more strongly reticulate female frons, by the more coarsely sculptured elytral disc, by the almost obsolete declivital striae, and by the much broader scales on the elytral declivity.

Female.- Length $1.8-2.2 \mathrm{~mm}, 3.0$ times as long as wide; color yellowish brown.

Frons rather strongly, transversely impressed from epistomal margin to well above eves, a small, median impression just below center; entire surface rather strongly rugosereticulate; vestiture fine, short, sparse. Scape bearing a rather dense fringe of long hair.

Pronotum 1.08 times as long as wide; sides almost straight and parallel on basal half, distinctly constricted on anterior half, broadly rounded in front; anterior margin unarmed; summit in front of middle; posterior area reticulate, punctures moderately abundant, rather small, shallow; vestiture of fine hair and stout bristles, rather short.

Elytra 1.8 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal three-fourths, broadly rounded behind; striae not impressed, punctures small, distinct; interstriae twice as wide as striae, irregularly subrugose, punctures small, obscure. Declivity convex, steep, confined to posterior fourth; striae very weakly impressed, punctures minute, distinct; interstriae almost smooth, with very fine, uniseriate, squamiferous granules, those on 3 very slightly larger. Vestiture of minute strial hair and uniseriate rows of erect interstrial scales; each scale on disc half as long as distance between rows, three times as long as wide; declivital scales three-fourths as long as distance between rows, two to three times as long as wide: a partial supplemental row along suture.

Male.-Similar to female except frontal impression reduced, not reaching upper level of eyes, central impression more pronounced, sculpture of upper half granulate; anterior margin of pronotum armed by six teeth; declivital granules very slightly larger.

Distribution.- Jalisco.
MEXICO: Jalisco: 24 km S Mazamitla, 22-VI-65, 2500 m, No. 94, S. L. Wood.

Biologr.- Specimens were cut from wood of branches of a leguminous tree with bipinnately compound leaves. The tunnels were as described for the genus.

Notes.- The above treatment was based on the type series of 10 specimens.

## 9. Thysanoes neotropicalis Wood

Thysanoes neotropicalis Wood, 1969, Brigham Young Sci. Bull., Biol. Ser. 10(2):35 (Holotype, female; San Ignacio de Acosta, San José, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from the closely allied fimbricornis LeConte by characters summarized in the above key.

Female.- Length $2.0-2.2 \mathrm{~mm}$ (males $1.5-1.9 \mathrm{~mm}$ ), 3.2 (male 2.6 ) times as long as wide; color medium brown.

Frons broadly, somewhat transversely impressed from epistoma to upper level of eyes, central area more narrowly impressed, subfoveate; epistomal area smooth and shining to subfoveate impression, sides and above finely, obscurely punctured and finely, closely, subaciculately granulate; vestiture inconspicuous. Tuft of setae on scape much smaller than in mexicanus.

Pronotum 1.2 times as long as wide; slightly wider near middle, sides straight and diverging anteriorly on basal half, converging slightly anteriorly toward broadly rounded, subserrate, anterior margin; summit almost one-third pronotum length from anterior margin; posterior area reticulate and very finely punctured; vestiture confined to marginal areas consisting of flattened bristles.

Elytra 2.1 times as long as wide, 1.8 times as long as pronotum; sides straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, punctures small, shallow; interstriae about twice as wide as striae, subshining, irregular but not clearly marked by lines or punctures. Declivity convex, steep; surface dull, strial punctures smaller than on disc, perhaps deeper; interstriae with occasional fine granules. Vestiture confined to declivity, consisting of erect interstrial scales, with an additional, partial row at suture; each scale three to four times as long as wide.

Male.-Similar to female except smaller, stouter, 2.6 times as long as wide; frons less extensively impressed; anterior margin of pronotum armed by 10 serrations; elytra with strial punctures much larger and deeper, interstrial punctures uniseriately granulate toward declivity, both strial punctures and moderately large interstrial granules continuing to apex of declivity; declivital vestiture longer and extending well onto disc.

Distribution.- Costa Rica.
COSTA RICA: San Ignacio de Acosta, San José, 5-V$63,1500 \mathrm{~m}$, Calliandra confusa, S. L. Wood.

Biology.- As described for the genus.
Notes.- The above treatment was based on the type series of 24 specimens.

## 10. Thysanoes fimbricornis LeConte

Fig. 143
Thysanoes fimbricornis LeConte, 1876, Proc. American Philos. Soc. 15:370 (Lectotype, female; Lancaster Co., Pennsylvania; Mus. Comp. Zool., No. 964. present designation)
Diagnosis.- This is the most common and widely distributed species in the genus. It is distinguished from all other species by the pale yellowish brown color, by the large tuft of hair on the female scape, by the female frontal excavation extending above the eyes, and by other characters summarized in the above key.

Female.- Length $1.4-2.1 \mathrm{~mm}, 3.0$ (male 2.5) times as long as wide; color light yellowish brown.

Frons shallowly concave to upper level of eyes; rather finely rugose-reticulate above, smooth, shining on lower third, foveate at center; glabrous. Antennal scape ornamented by abundant, long hair.

Pronotum 1.1 times as long as wide; sides almost straight and parallel on basal half, rather narrowly rounded in front; anterior margin unarmed; summit in front of middle; posterior area reticulate, with a few fine, shallow punctures. Vestiture sparse, short, stout, confined to margins and asperate area.

Elytra 1.9 times as long as wide, 1.7 times as long as pronotum; outline as in inornatus; striae not impressed, punctures small, very shallow; interstriae smooth, twice as wide as striae, punctures uniseriate, minute. Declivity very steep, convex; strial punctures reduced, almost obsolete; interstrial punctures replaced by very fine granules. Vestiture of rows of minute strial hair and rows of erect, interstrial scales; each scale about four times as long as wide, spaced by distances within a row and between rows equal to length of a scale.

Male.-Similar to female except not as slender; frons less extensively impressed; scape ornamented by only about a dozen setae; anterior margin of pronotum armed by eight teeth; interstrial granules larger,
extending almost to base; interstrial scales slightly longer, each about four times as long as wide.

Distribution.- Illinois, Pennsyivania, and Florida to Durango and Hidalgo.

USA: District of Columbia: Washington. Florida: Oleno St. Pk., Sebring. Illinois: E St. Louis. Maryland: College Park. New Jersey: Haddon Heights, Westville. Mississippi: Corinth, Duko, Luka, Trimcane Swamp. North Carolina: Monroe, Tryon. Pennsylvania: Dauphin, Frankford, Harrisburg Gap, Hummelstown, Indiantown, Iroquois, Linglestown, Philadelphia, Rockville, Swarthmore. Texas: Brownsville, College Station, Dallas, Victoria. Virginia: Arlington, Falls Church, Rosslyn. West Virginia: Kanawha Station, Monongalia. MEXICO: Durango: 32 km SW EL Salto. Hidalgo: 45 km S Jacala. Tamaulipas: 8 km W Aniguo Morelos. Veracruz: 35 km SE Jalapa

Hosts.- Acacia sp., Acer rubrum, Carya sp., Celtis sp., Gleditsia triacanthos, Morus rubra, Quercus spp.

Biology.- As described for the genus.
Notes.- The above treatment was based on LeConte's syntypes and on 287 other specimens. LeConte named this species from a syntypic series. Because a lectotype has never been designated, I here designate the female in his series presently bearing the type label Type No. 964, in the LeConte Collection at the Museum of Comparative Zoology, as the lectotype of Thysanoes fimbricornis LeConte.

Fig. I43. Micracini spp., antenna and protibiae: 23, 23a, Thysanoes fimbricornis, female, anterior and posterior faces, 24 , same, male, anterior face, 27 , same, female, posterior face; 25 , Thysanoes lobdelli, female, anterior face, 28 , same, posterior face; 26, Thysanoes berchimiae, female, anterior face, 29, 29a, same, posterior face, tarsus; 30, Pseudothysanoes dislocatus, female, 31, same; 32, Liparthrum squamosum, female, posterior face, 33, same, anterior face, 34, same, posterior face; 35, Pseudothysanoes rigidus, female, anterior face, 35, same, posterior face. (After Blackman 1920:pl. III.)

## 11. Thysanoes adonis Wood

Thysanoes adonis Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):36 (Holotype, female; 47 km W Quiroga, Michoacán, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from the allied subsulcatus Wood by characters summarized in the above key.

Female.- Length $1.4-2.0 \mathrm{~mm}, 2.6$ times as long as wide; color dark brown, summit of pronotum reddish brown.

Frons convex above, transversely impressed on lower half of area below upper level of eyes, a small median, subfoveate impression at center, ascending toward epistomal margin; surface densely, minutely, evidently subrugosely punctured in convex area, becoming almost smooth toward epistoma; vestiture of sparse, moderately long, very stout bristles uniformly distributed on convex area. Scape bearing about a dozen long hairs.

Pronotum 1.04 times as long as wide; sides almost straight and parallel on basal half, moderately constricted on anterior half, rather broadly rounded in front; anterior margin subserrate; summit at middle, rather broad; asperities on anterior slope rather coarse; posterior areas reticulate, punctures minute, sparse, a few behind summit minutely granulate; vestiture of stout bristles.

Elytra 1.6 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal three-fourths, rather broadly rounded behind; striae not impressed, punctures small, distinct; interstriae about three times as wide as striae, surface irregular, subrugose, punctures small, uniseriate, finely granulate on posterior half. Declivity convex, steep, restricted to posterior fourth; strial punctures obsolete, except some of them very finely granulate; interstriae uniseriately, finely granulate; general surface somewhat dull. Vestiture of very minute strial hair, and uniseriate rows of much longer, interstrial scales; each scale on disc about two-thirds as long as distance between rows, about four times as long as wide; scales on declivity slightly longer than distance between rows, about six times as long as wide, with a smaller supplemental row at suture.

Male.- Similar to female except anterior margin of pronotum more distinctly serrate; elytral granules smaller; declivital strial
punctures minute but visible; declivital scales broader, about four to five times as long as wide.

Distribution.- Michoacán.
MEXICO: Michoacán: 29 km W Quiroga, 17-Vl-65, 2200 m, Quercus, S. L. Wood.

Biology.- As described for the genus.
Notes.- The above treatment was based on the type series of nine specimens.

## 12. Thysanoes subsulcatus Wood

Thysanoes subsulcatus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):35 (Holotype, female; 8 km W Tulancingo, Hidalgo, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from fimbricornis LeConte by the larger size, by the more deeply impressed female frons, by the rather large interstrial declivital granules, and by the much longer, more slender declivital scales.

Female. - Length $1.9-2.3 \mathrm{~mm}, 3.0$ times as long as wide; color dark reddish brown.

Frons shallowly, broadly concave from epistoma to vertex, with a small, median impression near upper level of eyes; surface strongly reticulate, almost subrugose, except transversely etched on a rather large area above epistomal margin; vestiture short, stout, sparse, uniformly distributed. Scape with a small fringe of hair.

Pronotum 1.2 times as long as wide; sides straight and parallel on slightly less than basal two-thirds, very broadly rounded in front, anterior margin unarmed; summit well in front of middle, broad; surface strongly reticulate, punctures minute, very feebly granulate behind summit; vestiture fine, hairlike in posterior areas, stout bristles in asperate areas.

Elytra 2.0 times as long as wide, 1.9 times as long as pronotum; sides straight and parallel on slightly more than basal two-thirds, broadly rounded behind; striae not impressed, punctures very fine, shallow, distinct; interstriae more than twice as wide as striae, minutely irregular, punctures fine, obscure. Declivity steep, convex; strial punctures almost obsolete; interstriae 2 slightly elevated, each interstriae uniseriately, rather finely granulate, except punctures and granules obsolete on lower three-fourths of 1 . Vestiture consisting of very minute, fine,
strial hair, and uniseriate rows of longer, erect, interstrial scales; each scale on disc about half as long as distance between rows and three times as long as wide, on declivity slightly longer than distance between rows and up to six times as long as wide, obsolete on middle half of declivital interstriae 1.

Male.-Similar to female except frontal concavity deeper, extending only to upper level of eyes; anterior margin of pronotum armed by eight small teeth; discal strial punctures slightly larger, interstrial punctures granulate on posterior third; declivital granules much larger; declivital scales slightly wider and longer.

Distribution.- Hidalgo.
MEXICO: Hidalgo: 8 km W Tulancingo, ll-V1-67. 2400 m , Quercus, S. L. Wood.

Brology.- As described for the genus.
Notes.- The above treatment was based on the type series of 10 specimens.
13. Thysanoes texanus Blackman

Fig. 144

Thysanoes texanus Blackman, 1943, Proc. U.S. Nat. Mıs., 93:35:3 (Holotype, female; Brownsville, Texas; U.S. Nat. Mus., 56404)
Thysanoes cachelliae Blackman, 1943, Proc. U.S. Nat. Mus. 93:353 (Holotype, female; Brownsville, Texas; U.S. Nat. Mus., 56405 ); Wood, 1973, Great Basin Nat. 33:186. Synonymy
Thysanoes ratamae Blackman, 1943, Proc. U.S. Nat. Mus. 93:354 (Holotype, female; Mexico: U.S. Nat. Mus., 56406); Wood, 1973, Great Basin Nat. 33:186. Synonymy
Diagnosis.- The female of this species has a weak longitudinal carina in the upper half of the frontal concavity indicating a relationship to lobdelli Blackman and xylophagus Blackman. The relationship to those species, however, is remote. It is distinguished from them by the smaller size, by the weakly developed female frontal carina, by the less extensive female frontal impression, and by the larger, more deeply impressed strial punctures on the declivity.

Female.- Length $1.2-1.5 \mathrm{~mm}, 2.7$ (male 2.6) times as long as wide; color yellowish brown.

Frons broadly, rather deeply concave from epistoma to slightly above upper level of eyes, upper half with a weak median carina; finely reticulate-granulate above, gradually reduced until entirely smooth and shining on
epistomal area; vestiture fine, minute, inconspicuous. Antennal scape sparsely pubescent.

Pronotum 1.1 times as long as wide; widest at middle, sides weakly arcuate on basal half, slightly constricted anteriorly, then rather narrowly rounded in front; anterior margin unarmed; summit anterior to middle, rather well developed; dise reticulate, with a few very fine granules, lateral areas with an occasional, minute puncture. Vestiture of moderately abundant, stout, suberect setae.

Elytra 1.7 times as long as wide, 1.6 times as long as pronotum; outline as in inornatus; striae not impressed, punctures rather large, deep; interstriae smooth, as wide as striae, punctures granulate. Declivity very steep, convex; striae slightly impressed, punctures smaller than on disc, deep; interstriae closely, uniseriately granulate. Vestiture of minute strial hair and rows of erect, interstrial scales; each scale three to five times as long as wide on declivity, spaced by distances within and between rows by length of a scale; scales shorter and more widely spaced on disc.

Male.-Similar to female except frontal impression not concave, limited to lower half, with several large, isolated granules in convex area above, carina absent; anterior margin of pronotum armed by about six small teeth (variable); interstrial granules slightly larger; declivital scales up to one-half longer, four to six times as long as wide.

Distribution.-S Texas to Colima and Veracruz.

USA: Texas: Beeville, Brownsville, Southmost. MEXICO: Colima: 51 km S Colima. Jalisco: 8 km W Juchitlán, 24 km S Mazamitla, Volcán Colima. Nayarit: Los Corchos, 48 km N Rosamorada. Sinaloa: lsla de la Piedra. Tamanlipas: Jimenez, Llera. Veracruz: Cotaxtla, 5 km E Orizaba, 3 km S Rinconada.

Hosts.- Acacia spp., Mimosa spp., Prosopis juliflora.

Biology.- As described for the genus.
Notes.- The above treatment was based on the holotypes of texanus Blackman, vachelliae Blackman, and ratamae Blackman, and on 177 other specimens.

## 14. Thysanoes lobdelli Blackman

Fig. 143
Thysanoes lobdelli Blackman, 1920, Mississippi Agric. Expt. Sta. Tech. Bull. 9:43 (Lectotype, female; Trimcane Swamp, Mississippi; U.S. Nat. Mus., 24739, present designation)

Fig. 144. Micracini spp., antennae and protibiae: 11-14, Thysanoes texanus; 15, Pseudothysanoes huachucae; 16-17, Pseudothysanoes insularis (Cuba); 18, Pseudothysanoes colombianus (Colombia); 19-20, Pseudothysanoes acaciae; 21, Pseudothysanoes murilloi (Colombia); 22-24, Pseudothysanoes securigerus (Puerto Rico). (After Blackman 1943:pl. 30.)

Diagnosis.- This species evidently is distinguished from texanus Blackman and xylophagus Blackman in the female by the shallow, frontal concavity that extends well above the upper level of the eyes; it is provided with a long, uniformly elevated, median carina on its upper half, by the smaller strial punctures, and by the intermediate size and color.

Female.- Length $1.4-1.7 \mathrm{~mm}, 2.7$ times as long as wide; color dark reddish brown.

Frons shallowly, broadly concave from epistoma to well above eyes, upper half with a low, acutely elevated median carina; surface finely, obscurely reticulate and minutely punctured above, smooth and shining on median third of lower half; vestiture fine, moderately long, rather inconspicuous. Antennal scape moderately pubescent.

Pronotum 1.05 times as long as wide; widest just behind middle, sides weakly arcuate on more than basal half, weakly constricted on anterior half, broadly rounded in front; anterior margin unarmed; summit in front of middle, rather high; posterior area strongly reticulate, with a very few minute punctures and granules. Vestiture consisting of a few stout setae, mostly in marginal areas.

Elytra 1.7 times as long as wide, 1.6 times as long as pronotum; outline as in inornatus; striae not impressed, punctures small, rather deep; interstriae shining, rather irregular, about one and one-half times as wide as striae, uniseriately granulate. Declivity steep, convex; strial punctures much smaller, shallow; interstrial granules slightly smaller. Vestiture of rows of minute strial hair and rows of erect interstrial scales; each scale about four to six times as long as wide, spaced within a row by distances equal to length of a scale, between rows by three-fourths length of a scale.

Distribution.-Georgia and Florida to Louisiana and possibly Oaxaca.

USA: Florida: Monticello, 20-11-57, pecan. Georgia: Brunswick, Quercus. Louisiana: Creenwell Springs, 10-VI-51, Quercus, S. L. Wood. Mississippi: Picayune, 13-I45, Quercus; Nicholson, 8-XII-44, Quercus nigra, 30-I45. Castanea pumila; Trimcane Swamp, 27-111-20; Vicksburg, 5-III-20. MEXICO: Oaxaca: Totolapan, 7-V11-53, 1100 m, S. L. Wood.

Hosts.-Carya sp., Castanea pumila, Quercus sp.
Biology.- As described for the genus.

Notes.- The above treatment was based on the holotype and on 65 other specimens, including 3 females taken in Oaxaca. I see no characters that will separate the Oaxaca specimens into distinct taxa. Presumably future collecting will narrow the distributional gap. Blackman's "holotype" in the U.S. National Museum is actually a syntype; it is here designated as the lectotype of this species.

## 15. Thysanoes xylophagus Blackman

Thysanoes xylophagus Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Bull. 25:198 (Holotype, female: Williams, Arizona; U.S. Nat. Mus., 27135)

Diagnosis.- This species is distinguished from all other representatives of the genus by the abundant, short, broad interstrial scales, by the long, conspicuous female frontal vestiture, and by the short, strongly elevated, female, frontal carina.

Female.- Length $1.8-2.2 \mathrm{~mm}, 2.8$ times as long as wide; color almost black.

Frons deeply concave on median threefourths from epistoma to vertex, upper fourth with a short, strongly elevated, median carina; surface finely granulate above, obscurely reticulate in most of concavity, smooth and shining in median area below; vestiture coarse, long, conspicuous, usually concealing upper surface and carina. Antennal scape moderately pubescent.

Pronotum 1.04 times as long as wide; about as described for lobdelli except posterior area very finely, densely granulate-punctate. Vestiture of moderately abundant, fine, short, recumbent setae posteriorly, a few scales near summit, a few coarse bristles in asperate area.

Elytra 1.7 times as long as wide, 1.7 times as long as pronotum; outline as in inornatus; striae not impressed, punctures moderately coarse, deep; interstriae somewhat smooth, shining, slightly wider than striae, punctures uniseriate, close fine. Declivity steep, convex; strial punctures less definite, slightly smaller; interstrial punctures finely granulate, granules reduced and confused on lower third.

Vestiture of rows of minute strial hair and rows of erect, interstrial scales; each scale as short or shorter than strial hair, about twice as long as wide, spaced within a row by distances less than length of a scale, between rows by about one and one-third times length of a scale.

Male.-Similar to female except frontal excavation shallow, less extensive, carina absent; anterior margin of pronotum armed by about 10 teeth; interstrial punctures on disc weakly granulate; interstrial scales slightly shorter, each almost as wide as long.

Distribution.-Arizona and New Mexico to Durango.

USA: Arizona: Graham Mts., 5 -VIII-60, 2400 m , Qucrcus, S. L. Wood; Miller Canyon, Huachuca Mits., 10-VII-62, 7-VI-69, Quercus, S. L. Wood; Santa Catalina Mits., I3-IV-08, Quercus; Williams, 1, 6-VI, E. A. Schwarz. New Mexico: Emery Pass, Gila N.F., 5-VI-69, 2600 m , No. 60, Quercus, S. L. Wood; Peloncillo, V11907, Quercus, J. L. Webb. MEXICO: Durango: 37 km W Durango, 4-VI-65, 2000 m , Quercus, S. L. Wood.

Hosts.-Quercus spp.
Brology.- This species usually breeds in twigs of branches girdled by cerambycid beetles. The gallery system is modified into pith tunnels in tiny twigs.

Notes.- The above treatment was based on 2 paratypes and on 78 other specimens.

## Genus PHLOEOCLEPTUS Wood

Phlococleptus Wood, 1956, Canadian Ent. 88:147 (Typespecies: Phlooocleptus caudatus Wood, original designation)
Diagnosis.- This genus superficially resembles Hylocurus Eichhoff, but it may be distinguished by the smaller antennal club, with two straight sutures indicated only at the sides, by the absence of tubercles on the posterior face of the prothoracic tibiae, by the phloeophagous habit, and, in those species with declivital interstriae 9 elevated, by the elevated crest of interstriae 9 continuing posteriorly to join costal margin.

Description.- Length $1.0-1.8 \mathrm{~mm}$, 1.4-1.7 times as long as wide; color black. Frons convex, shallowly impressed in one species, not conspicuously dimorphic, simple. Antennal scape short, simple to strongly flattened, conspicuously sexually dimorphic, much more broadly flattened in female; funicle 6 -segmented; club small, narrow, widest on basal half, sutures 1 and 2 indicated by setae at sides, entirely obsolete in central area. Pronotum asperate on anterior slope, anterior margin armed in males of some species, females unarmed. Elytra striate-punctate, declivity sexually dimorphic, varying from simple to elaborately adorned in male of one species. Vestiture of fine hair and slender bristles.

Distribution.- N Mexico to Costa Rica; 11 species are known.

Biology.- The species are bigamous and phloeophagous. Parental tunnels include a nuptial chamber that very lightly scores the surface of the wood and two egg galleries that extend in opposite directions from the nuptial chamber parallel to the grain of the wood. The egg galleries stain the surface, but evidently do not engrave the wood; they are tightly packed with frass as the female progresses. The male remains in the nuptial chamber or abandons the tunnel. The egg galleries are unusually long for a beetle of this size. Larval mines wander indiscriminately and vary from short to rather long, presumably depending on environmental conditions. The beetles infest cut or broken branches $1-7 \mathrm{~cm}$ in diameter.

Notes. - Schedl (1959:42) proposed that this genus be made a synonym of Hylocurus Eichhoff, presumably without seeing a specimen. Although the male of the type-species bears a superficial resemblance to males of some Hylocurus, they are sufficiently distinct anatomically and biologically that two genera can be recognized without hesitation.

## Key to the Species of Phloeocleptus

1. Female frons broadly, moderately concave, male (apparently) with at least a
slight impression; scape slender, longer than club ..... 2

- Frons convex in both sexes; scape strongly compressed, shorter than club

2(1). Vestiture at upper margin of female frontal concavity short, inconspicuous; interstriae on posterior half of disc twice as wide as striae; Tres Marías Islands (Mexico); 1.9-2.0 mm

1. tresmariae (Schedl)

- Vestiture at upper margin of female frontal concavity dense, one-third as long as diameter of concave area; posterior half of discal interstriae narrower than striae; Costa Rica; tree branch; $1.6-1.7 \mathrm{~mm}$

2. punctatus Wood

3(1). Anterior margin of male pronotum unarmed; male discal interstriae devoid of granules

- Anterior margin of male pronotum armed by two to four teeth; male discal interstriae uniseriately granulate
4(3). Strial punctures on declivity sharply impressed, interstriae 1 and 2 devoid of granules; declivital surface brightly shining; Nayarit; $1.4-1.8 \mathrm{~mm}$

## 3. plagiatus Wood

- Strial punctures on declivity obscure to obsolete on lower half, interstriae 1 and 2 each with several fine granules; Nayarit; 1.3 mm

4. parvus Wood

5(3). Discal interstriae 9 usually less strongly elevated, elevation apically not joining costal margin; base of male declivity never with a circumdeclivital ring of tubercles; anterior margin of male pronotum with two to four serrations6

- Declivital interstriae 9 more strongly elevated, elevation apically joining costal margin; base of male declivity (except nanulus) with a circumdeclivital ring of tubercles poorly to strongly developed; anterior margin of male pronotum usually armed by four serrations 8
6(5). Declivital interstriae 9 slightly elevated only at base, 2 reduced and without tubercles or interstrial setae except at extreme base; anterior margin of male pronotum armed by two large serrations; San Luis Potosí; Persea americana; $1.0-1.2 \mathrm{~mm}$ 5. obscurus Wood
- Declivital interstriae 9 moderately elevated, continuing on a descending course to suture (sometimes represented near suture only by granules), 2 armed by tubercles and with interstrial setae at least on upper half; anterior margin of male pronotum armed by two to four serrations .7

7(6). Smaller; declivital interstriae 9 moderately elevated, anterior and posterior ends of crest very gradual; declivity more evenly convex, tubercles on 7 and 8 smaller, extending further from base; strial punctures on disc coarser, interstrial granules larger; Michoacán; Persea; 1.1-1.2 mm ...........6. atkinsoni Wood

- Larger; declivital interstriae 9 strongly elevated, anterior and posterior ends of crest rather abrupt; declivity somewhat impressed in posterolateral areas, tubercles on 7 and 8 larger, nearer base; strial punctures on disc smaller, interstrial granules smaller; Morelos; Persea; 1.2-1.4 mm

7. cristatus Wood

8(5). Declivital interstriae 2 armed by a row of fine tubercles, declivital interstrial setae moderately to strongly flattened, at least in male; discal interstriae in male with rather coarse tubercles on more than posterior half; serrations on anterior margin of male pronotum rather coarse, conspicuous9

- Declivital interstriae 2 unarmed, interstrial setae hairlike in both sexes; male discal interstriae with tubercles much smaller, confined to posterior half; serrations on anterior margin of male pronotum almost obsolete
. 10
9(8). Male declivity strongly convex, without a circumdeclivital ring of interstrial tubercles; posterolateral margin of declivity feebly serrate; frons convex in both sexes; Nayarit; tree branches; 1.5-1.6 mm

8. nanulus Wood
Male declivity strongly excavated in lateral areas, with a very strongly ele-
vated, circumdeclivital ring of large nodules; posterolateral margin of declivity
rather coarsely serrate in both sexes; female frons shallowly concave in small
median area; Puebla; tree branches; $1.4-1.6 \mathrm{~mm} . . . . . . . . . . . . . . . . . . . . . . . . ~ 9 . ~ c a u d a t u s ~ W o o d ~$
$10(8)$. Frons more strongly convex and moderately punctured; male scape with a sparse tuft of hair; male declivity with interstrial denticles in circumdeclivital row slightly larger and more sharply pointed; Nuevo León; Persea; 1.0-1.2 mm 10. spicatus Wood

Male frons distinctly flattened in central area, punctures sparse, minute; male scape with a large tuft of long hair; tubercles in male circumdeclivital ring smaller, less sharply pointed; Nuevo León; Persea; 1.7-1.9 mm
11. ardis Wood

## 1. Phloeocleptus tresmariae (Schedl)

Hylocurus tresmariac Schedl, 1956, Pan Pacific Ent. 32:32 (Holotype, female?; village on Maria Madre, Tres Marías Islands, Gulf of California; California Acad. Sci.)
Diagnosis.-Generic characters clearly place this species in Phloeocleptus near plagiatus Wood. It is distinguished, however, by the slender, elongate scape, by the absence of an elevation on declivital interstriae 9 , by the more broadly, evenly convex elytral declivity, and by several other characters.

Female (?).- Length $1.9-2.0 \mathrm{~mm}, 2.5$ times as long as wide; color very dark brown, vestiture almost white.

Frons moderately, rather broadly concave from epistoma to upper level of eyes; surface smooth, shining in concavity, with a few minute punctures, marginal areas subreticulately etched; vestiture very fine, sparse, inconspicuous. Antennal scape long, slender, slightly longer than club, ornamented by several long setae; club with two complete, straight to feebly recurved sutures.

Pronotum 1.07 times as long as wide; widest on basal half, sides weakly arcuate, feebly converging at middle, weakly constricted on anterior half, rather narrowly rounded on unarmed anterior margin; summit at middle, anterior area asperate; posterior area reticulate-granulate behind summit, with a few isolated granules, becoming more finely reticulate with a few, fine punctures laterally. Vestiture of sparse, stout setae.

Elytra 1.4 times as long as wide, 1.4 times as long as pronotum; outline as in plagiatus; striae not impressed, punctures moderately coarse, rather deep; interstriae smooth, shining, twice as wide as striae, punctures
uniseriate, half as large as those of striae. Declivity steep, evenly convex except for apical mucro; striae indistinctly impressed, punctures slightly smaller; interstriae as wide as striae, each with a uniseriate row of rather coarse, rounded granules. Vestiture of rows of minute strial hair, and rows of erect interstrial scales; each scale about five times as long as wide, spaced between rows by length of a scale, closer within a row.

Distribution.- Tres Marías Islands, Gulf of California.

MEXICO: Tres Marías Islands: María Madre, 15-V25, H. H. Keifer.

Notes.- The above treatment was based on the holotype and a male paratype. In my opinion the holotype could be a male, not a female as stated by Schedl.

In the original description Schedl clearly designated a holotype that was deposited in the California Academy of Sciences collection along with one male paratype; therefore, the "holotype" and "allotype" in his collection have status only as paratypes, contrary to the labels they bore when I examined them in 1965.

## 2. Phloeocleptus punctatus Wood

Phlococleptus punctatus Wood, 1980, Great Basin Nat. 40:355 (Holotype, female; Santa Rosa N.P., Guanacaste Prov., Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from tresmariae (Schedl) by the slightly smaller size, by the fringe of long setae at the upper margin of the female frontal concavity, by the coarser strial punctures, and by other characters cited below.

Male.- Length $1.6-1.7 \mathrm{~mm}$ (female 1.8 mm ), 2.4 (female 2.6) times as long as wide; color very dark brown.

Frons convex, a slight transverse impression just above epistoma; surface rugose-reticulate on lower half, more irregularly rugose above, punctures moderately coarse, rather close. Antennal scape slender, elongate, ornamented by fewer than a dozen long setae.

Pronotum about as in tresmariae except anterior margin finely serrate and sparse vestiture on posterior half a mixture of fine, slender hair and stout scales.

Elytral outline about as in tresmariae; striae distinctly impressed on posterior third of disc, punctures at base rather small, gradually increasing to twice as large and very deep at base of declivity; interstriae slightly wider than striae at base, narrower than striae at base of declivity, punctures uniseriate, fine at base, becoming replaced by rounded granules near base of declivity. Declivity broadly, strongly convex, steep; strial punctures decrease in size from base, moderately coarse at apex; interstriae as wide as striae on lower half, all uniseriately granulate to apex. Vestiture of erect, uniseriate scales, each three to four times as long as wide, almost as long as distance between rows, spaced within a row by about two-thirds length of a scale.

Female.-Similar to male except more slender; frons moderately concave almost from eye to eye from epistoma to vertex, its surface minutely irregular, punctures fine, obscure, its upper margin ornamented by a dense fringe of long hair, these setae equal in length to about one-third diameter of concave area; scape with a larger tuft of long setae; anterior margin of pronotum unarmed; elytral punctures and granules distinctly smaller, interstrial scales each four to five times as long as wide.

Distribution.- Costa Rica.
COSTA RICA: Santa Rosa N.P., Guanacaste Prov., 15-XII-79, 6-I-80, phloem of tree branch, G. Stevens.

Notes.- The above treatment was based on the type series of five specimens.

## 3. Phloeocleptus plagiatus Wood

Phlococleptus plagiatus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):45 (Holotype, male; 7 km W Tepic, Nayarit, Mexico: Wood Coll.)
Diagnosis.- This species is distinguished from obscurus Wood by the much larger size,
by the transverse impression of the lower frons and presence of a low median elevation above, by the absence of teeth on the anterior margin of the male pronotum, and by the somewhat more strongly elevated declivital interstriae 9.

Male.- Length $1.4-1.8 \mathrm{~mm}, 1.4$ times as long as wide; color very dark brown, almost black in mature specimens.

Frons convex above, a moderate, transverse impression at level of antennal insertion; a short, longitudinal, median carina at upper level of eyes; surface smooth and shining at center below, becoming coarsely reticulate elsewhere, finely punctured toward smooth area, a few fine granules laterally and above; vestiture inconspicuous except near epistoma. Antennal scape short, about two and one-half times as long as wide, bearing a small tuft of hair; club small, two straight sutures indicated by setae only at lateral margins.

Pronotum 1.0 times as long as wide; sides almost straight on posterior half, converging to a feeble constriction just anterior to middle, rather broadly rounded on unarmed anterior margin; anterior slope asperate to summit; summit at middle; posterior area rather coarsely reticulate, with small, isolated granules decreasing in abundance toward basal margin, granules replaced by minute punctures in lateral areas. Vestiture moderately abundant, consisting of stout, hairlike setae, longer in median area behind summit.

Elytra 1.4 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal two-thirds, subacutely mucronate behind; striae feebly if at all impressed, punctures of moderate size and depth; interstriae shining, as wide as striae, punctures fine, uniseriate. Declivity convex, steep; strial punctures reduced, obscured by subgranulate reticulation of entire declivital surface; interstriae each armed on upper half by a series of small tubercles, 1 and 3 feebly elevated, 9 more strongly raised and subcarinate on basal half; apex gradually extended toward poorly developed mucro. Vestiture on disc and declivity consisting of fine, erect strial hair, and slightly longer, moderately stout interstrial bristles; more conspicuous on declivity.

Female.- Similar to male except antennal scape triangular and bearing a larger tuft of hair; elytral vestiture finer and somewhat shorter.

Distribution.- Nayarit.
Mexico: Nayarit: 7 km W Tepic, 13 -VII-65, 1000 m , No. 240, S. L. Wood.
Biology.- Specimens were removed from the cambium region of a cut branch of a large roadside shade tree. The tunnels were biramous, longitudinal, and mostly in the phloem.

Notes.- The above treatment was based on the type series of 35 specimens.

## 4. Phloeocleptus parvus Wood

Phloeocleptus parvus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):46 (Holotype, male; Los Corchos, Nayarit, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from plagiatus Wood by the more slender antennal scape, by the presence of several rather large punctures on the base of the pronotum, and by the reduced number of tubercles on the elytral declivity.

Male.-Length $1.3 \mathrm{~mm}, 2.6$ times as long as wide; color dark brown (probably not fully mature).

Frons not visible. Scape little if any wider than pedicel, about three times as long as wide.

Pronotum 1.16 times as long as wide; widest behind middle, sides feebly arcuate, almost straight and parallel on basal twothirds, broadly rounded in front; anterior margin unarmed; summit in front of middle; posterior area reticulate, a few small, isolated granules near summit, several moderately large, deep punctures toward basal margin and in entire lateral area; vestiture fine, largely abraded.

Elytra 1.5 times as long as wide, 1.3 times as long as pronotum; outline and disc as in plagiatus. Declivity steep, convex, shining to apex; strial punctures slightly confused; interstriae 1 and 2 unarmed, 2 greatly narrowed near middle, 3 armed by a tubercle at middle and another at junction with 7,7 also bearing a small tubercle at declivital base, 9 more strongly elevated than in plagiatus. Vestiture confined to declivity, consisting of very short strial and moderately long, stout interstrial bristles.

Distribution.- Nayarit.
MEXICO: Nayarit: Los Corchos, IO-VII-65, 10 m , No. 206, S. L. Wood.

Biology.- The type specimen was taken from a broken branch of an unidentified tree.

Notes.- The above treatment was based on the unique holotype.

## 5. Phloeocleptus obscurus Wood

Phloeocleptus obscurus Wood, 1956, Canadian Ent. 88:148 (Holotype, male; El Salto, San Luis Potosí, Mexico; Snow Ent. Mus., Univ. Kansas)
Diagnosis.- This species is distinguished from nanulus Wood by the smaller size, by the presence of granules on the upper part of the declivital face, and by other characters mentioned in the above key.

Male.- Length $1.0-1.2 \mathrm{~mm}, 2.5$ times as long as wide; color dark brown to almost black.

Frons convex, a weak, transverse impression just above epistoma; surface shining, subreticulate on marginal areas, almost smooth at center, with moderately sparse, isolated, minute granules widely distributed; vestiture fine, inconspicuous. Antennal scape short, flattened; club about as in caudatus Wood.

Pronotum 1.0 times as long as wide; as in plagiatus Wood except anterior margin armed by two coarse teeth, posterior area less distinctly reticulate.

Elytra 1.5 times as long as wide, 1.4 times as long as pronotum; outline as in plagiatus; striae not impressed, punctures moderately large, impressed; interstriae shining, narrower than striae, uniseriately granulate. Declivity very steep, convex; strial punctures reduced, rather obscure; interstrial granules extend to upper fourth, obsolete below except extended to near or below middle on 1 and 3,9 not joining costal margin. Interstrial bristles on declivity slightly longer and distinctly stouter than in plagiatus.

Female.- Similar to male except declivital scales wider, more strongly pubescent; anterior margin of pronotum unarmed; interstrial granules almost obsolete on disc.

Distribution.- San Luis Potosí.
MEXICO: San Luis Potosí: El Salto, 19-VI-53, Avocado, S. L. Wood.

Host.- Persea americana.
Biology.- Specimens were taken from small, unthrifty twigs of a living avocado tree.

Notes.- The above treatment was based on nine paratypes.

## 6. Phloeocleptus atkinsoni Wood

Phlococleptus atkinsoni Wood, 1981, Great Basin Nat. 41:124 (Holotype, male: Uruapan, Michoacán, Mexico.
Diagnosis.- This species is distinguished from obscurus Wood by the elevated crest of declivital interstriae 9 continuing almost to the suture, by the presence of tubercles on declivital interstriae 2, and by the presence of four serrations on the anterior margin of the pronotum.

Male.- Length 1.1-1.2 mm, 2.7 times as long as wide; color almost black except summit of pronotum almost reddish brown.

Frons broadly convex; surface apparently finely granulate-punctate.

Pronotum similar to obscurus except constriction on anterior half more pronounced and posterior areas conspicuously reticulategranulate; anterior margin armed by four equal, subcontiguous serrations.

Elytra similar to obscurus except strial punctures on disc conspicuously larger, deeper, interstrial granules larger, moderately elevated, crest of interstriae 9 continuing at least to striae 2, declivital interstriae 2 armed by granules and bearing setae similar to those of 1 and 3 , vestiture more slender and longer.

Female.- Similar to male except antemal scape more strongly expanded and ornamented by a larger tuft of hair, anterior margin of pronotum unarmed by serrations, and declivital interstriae 9 less strongly elevated.

Distribution.- Michoacán.
MEAICO: Michoacán: Uruapan, 17-11-80, No. S-026, 1600 m . Persea, T. H. Athinson.
Notes.- The above treatment was based on the type series of five specimens.

## 7. Phloeocleptus cristatus Wood

Phlococleptus cristatus Wood, 1981, Great Basin Nat. 41:125 (Holotype, male; Tepoztlan, Morelos, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from obscurus Wood by the larger size and by the very different elytral declivity as described below.

Male.- Length 1.2-1.4 mm, 2.4 times as long as wide; color almost black except summit of pronotum almost reddish brown.

Frons and pronotum about as in obscurus except anterior margin of pronotum armed by four rather widely spaced serrations, lateral pair submarginal.

Elytral disc about as in obscurus except most interstrial punctures obscurely or incompletely replaced by granules; declivity more broadly convex, somewhat impressed in ventrolateral areas, interstriae 9 strongly, acutely elevated, anterior and posterior limits of this elevation rather abrupt, elevation ending posteriorly at striae 3 but with tubercles on interstriae 1 and 2 suggesting a continuation of it, interstriae 2 with a row of fine tubercles and setae on upper half, vestiture more slender.

Female.- Similar to male except antennal scape slightly larger and with a larger tuft of setae, anterior margin of pronotum unarmed, declivital interstriae 9 less strongly elevated, more conspicuously serrate.

Distribution.- Morelos.
Mexico: Morelos: Tepoztlan, 20-VI-80, No. S-071, Persea, T. H. Atkinson.

Notes.- The above treatment was based on the type series of five specimens.

## 8. Phlococleptus nanulus Wood

Phlococleptus nanulus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. $10(2): 45$ (Holotype. male: 7 km W Tepic, Nayarit, Mexico; Wood Coll.)
Diagnosis.- This species is allied to caudatus Wood, but it is much more likely to be confused with plagiatus Wood, from which it differs by the uniformly convex frons, by the armed anterior margin of the pronotum in both sexes, by the interstrial granules on the male disc, by the greater development of tubercles at the base of the elytral declivity, and by the more strongly elevated interstriae 9.

Male.- Length $1.5-1.6 \mathrm{~mm}, 2.5$ times as long as wide; color almost black.

Frons convex except epistomal margin weakly elevated; surface subreticulate, with small isolated granules (except almost smooth in median epistomal area); vestiture inconspicuous. Antennal scape short, about twice as long as wide, bearing a small tuft of hair.

Pronotum 1.0 times as long as wide; outline as in plagiatus except anterior margin
armed by four teeth, median pair larger; sculpture as in plagiatus, vestiture coarser.

Elytra about 1.6 times as long as wide, 1.6 times as long as pronotum; outline as in plagiatus; striae perhaps feebly impressed, punctures rather small, deep, larger posteriorly; interstriae almost as wide as striae, punctures finely granulate (subvulcanate), granules slightly larger near declivity. Declivity steep, convex; as in plagiatus except all tubercles slightly larger, particularly those at base of declivity in lateral areas; interstriae 9 much more strongly elevated. Interstrial bristles on declivity longer and coarser than in plagiatus.

Female.- Similar to male except antennal scape longer, wider, and bearing a larger tuft of hair; anterior margin of pronotum armed by two small teeth; discal interstriae not granulate; lateral declivital tubercles smaller, interstriae 9 not as strongly elevated; declivital vestiture not as coarse.

Distribution.- Nayarit.
MEXICO: Nayarit: 7 km W Tepic, 13 -VI-65, 1000 m , No. 240, S. L. Wood.

Brology.- The type series was taken from the same cut branch that contained the type series of plagiatus. The gallery system was similar to plagiatus.

Notes.- The above treatment was based on the type series of three specimens.

## 9. Phloeocleptus caudatus Wood Fig. 145

Phloeocleptus caudatus Wood, 1956, Canadian Ent. 88:147 (Holotype, male; 9 km NE Teziutlán, Puebla, Mexico; Snow Ent. Mus., Univ. Kansas)
Diagnosis.- This species is distinguished from the allied nanulus Wood by the more strongly impressed strial punctures, by the shallowly concave female frons, by the strongly developed circumdeclivital row of tubercles on the male declivity, and by the larger size.

Male.- Length $1.4-1.6 \mathrm{~mm}, 2.5$ times as long as wide; color black.

Frons as in obscurus except somewhat flattened in central area, central area with minute punctures rather than granules. Scape weakly flattened.

Pronotum 1.0 times as long as wide; as in plagiatus except anterior margin armed by
four teeth and granules behind summit larger.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; sides straight to widest point at declivital margin, abruptly converging behind to obtusely angulate apical mucro; striae impressed near declivital margin, punctures deep, moderately small at base, gradually increasing posteriorly until very large near declivity; interstriae shining, as wide as striae at base, half as wide at declivital margin, granules at base fine, moderately large toward declivity, last tubercle on each interstriae at declivital margin extremely large, forming part of a circumdeclivital ring. Declivity truncate, very steep, protruding somewhat in median area below; striae 1 and 2 clearly punctured, others confused; interstriae 1,2 , and 3 each bearing on upper half a row of small, pointed tubercles; acute elevation of interstriae 9 joining costal margin and continuing to apex, serrate. Vestiture about as in plagiatus but longer and coarser on declivital margin.

Female.- Similar to male except central area of frons shallowly concave; anterior margin of pronotum unarmed; elytra as in female of obscurus except strial punctures larger, vestiture longer, and declivity more flattened and impressed in lower, lateral areas.

Distribution.- Puebla.
MEXICO: Puebla: 8 km NE Teziutlán, 27-VI-53, 1600 $\mathrm{m}, \mathrm{S}$. L. Wood.

Biology.- Specimens were taken from the cambium region of a broken branch of a roadside tree that superficially resembled magnolia.

Notes.- The above treatment was based on nine paratypes.

## 10. Phloeocleptus spicatus Wood

Phloeocleptus spicatus Wood, 1981, Great Basin Nat. 41:125 (Holotype, male; Cerro Chipinque, Monterrey, Nuevo León, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from caudatus Wood by the smaller size, by the antennal scape being wider than long in both sexes, by the absence of tubercles on declivital striae 2 in both sexes, and by the very different male declivity.

Male.- Length $1.0-1.2 \mathrm{~mm}, 2.4$ times as long as wide; color almost black except summit of pronotum almost reddish brown.

1. H. equidens

2. H. medius

3. $H$. inaequalis

Fig. 145. Micracini spp., elytral declivities, antennae, and protibiae: 1, Hylocurus equidens, male; 2, Hylocurus medius, male; 3, Hylocurus inaequalis, male; 4, Hylocurus effeminatus, male; 5, Micracis lignator (=truncatus), male; 6, Pseudothysanoes spinatus, male; 7-10, Phloeocleptus caudatus, 7, 10, male, 8-9, female. (After Wood 1956:145.)

Frons broadly convex, finely, unevenly rugose. Antennal scape as wide as long, ornamented by a small tuft of hair.

Pronotum about as in caudatus except serrations on anterior margin poorly, irregularly formed.

Elytra with sides almost straight and parallel on basal three-fourths, abruptly subtruncate at declivity, submucronate behind; striae weakly impressed on posterior half of disc, punctures sharply, deeply impressed, increasing in size posteriorly; interstriae slightly wider than striae at base, slightly narrower at base of declivity, punctures small, obscure, apparently uniseriate, granulate near declivity, except on 1 and 2 extending to middle of disc. Declivity moderately abrupt, steep, convex; basal margin with a circumdeclivital ring of moderately large, sharply pointed spines on 2 to 8 , spine on 3 positioned slightly behind others, subserrate on 9 to apex; strial punctures continuing to declivity, coarse deep; interstriae 1 and 3 weakly elevated, each with a row of fine denticles on basal half. Vestiture of rows of short strial and longer interstrial hair.

Female.-Similar to male except scape much more strongly widened and with a larger tuft of hair; anterior margin of pronotum unarmed; strial punctures small, not enlarged posteriorly; declivity more gradually, evenly convex, without a circumdeclivital row of spines, interstriae 9 only slightly elevated.

Distribution.- Nuevo León.
MEXICO: Nuevo León: Cerro Chipinque, Monterrey, 30-I-80, 1300 m , No. S-020, Persea, T. H. Atkinson.

Notes.- The above treatment was based on the type series of four specimens.

## 11. Phloeocleptus ardis Wood

Phloeocleptus ardis Wood, 1981, Great Basin Nat. 41:124 (Holotype, male; Cerro Chipinque, Monterrey, Nuevo León, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from spicatus Wood by the larger size, by the slightly flattened, smoother, more finely punctured frons, by the less abrupt, more evenly convex male declivity, and by the smaller circumdeclivital male spines.

Male.- Length $1.7-1.9 \mathrm{~mm}, 2.5$ times as long as wide; almost black except pronotal summit reddish brown.

Frons as in spicatus except central third almost subconcavely impressed, smooth, shining, with a few obscure, minute punctures. Scape broad, with a large tuft of long, yellow hair.

Pronotum as in spicatus.
Elytra about as in spicatus except discal punctures slightly smaller, base of declivity less abrupt, spines in circumdeclivital ring distinctly smaller, much less sharply pointed, declivital punctures slightly smaller, vestiture finer.

Distribution.- Nuevo León.
MEXICO: Nuevo León: Cerro Chipinque, Monterrev, $30-\mathrm{I}-80,1300 \mathrm{~m}$, No. S-020, Persea, T. H. Atkinson.

Notes. - The above treatment was based on the type series of five males.

## Genus MICRACIS LeConte

Micracis LeConte, 1868, Trans. Amer. Ent. Soc. 2:164 (Type-species: Micracis suturalis LeConte, subsequent designation by Hopkins, 1914, Proc. U.S. Nat. Mus. 48:125)
Diagnosis.- This genus is allied to Hylocurus Eichhoff and Micracisella Blackman, with which it shares the procurved sutures of the antennal club and the strongly acuminate and mucronate elytral apex. It differs from these genera by the more strongly flattened antennal scape, by the much more strongly procurved sutures of the antennal club, and by the more strongly flattened anterior tibiae, with all teeth on the distal margin; its posterior face is smooth. It also differs from Micracisella in having the anterior margin of the eye entire.

Description.- Length $1.6-3.4 \mathrm{~mm}$, females averaging very slightly larger than males; females 3.0-3.5, males $2.6-3.0$ times as long as wide; color light to dark yellowish or reddish brown.

Frons dimorphic, in females broadly impressed and shallowly to strongly concave from epistoma at least to upper level of eyes, convex in males; sculpture and vestiture conservative. Eye elongate-oval, entire; rather coarsely faceted. Antennal scape rather short, triangularly flattened, strongly so in females, and elaborately ornamented by long hair; funicle 6 -segmented; club elongate-oval with two strongly procurved sutures indicated by setae, suture 1 extending one-third to twothirds club length from base. Pronotum
longer than wide, summit anterior to middle; anterior area asperate; anterior margin armed by eight to 12 teeth in male, often unarmed in female; posterior area variously reticulate, with a few isolated granules. Scutellum large. Elytra with sides straight and parallel on basal three-fourths, strongly acuminate and mucronate behind; declivity confined to posterior fourth; striae usually not at all impressed, punctures fine but always present in rows; interstrial punctures fine, uniseriate, commonly granulate. Declivity steep, convex: conservatively sculptured. Vestiture of rows of very fine, short strial hair, and rows of longer, erect, interstrial setae; interstrial setae hairlike to scalelike.

Anterior coxae contiguous in a few species, separated in most.
Distribution.- United States to Panama, South America, and Africa; 18 species are known to occur north of Panama, and several others have been named from South America and Africa.

Biology.- The habits are basically as in Thysanoes and Hylocurus. Weakened, unthrifty, broken, or cut branches or seedlings about $2-4 \mathrm{~cm}$ in diameter are selected for attack, except up to 15 cm in lepidus Wood. The male extends the entrance tunnel through the bark and well into the wood, where an elongated nuptial chamber is formed. He is normally joined by two females, each of which constructs two rather long egg tunnels extending from the ends of the nuptial chamber in a more or less diagonal direction, always in the xylem but most commonly rather close to the cambium. The small eggs are placed in niches. The larvae progress very slowly; their mines almost always parallel the grain of the wood and they usually are rather long for a beetle of this size. Young adults commonly feed just below the cambium for a considerable period of time before emerging through individual exit holes.

## Key to the Species of Micracis

1. Frons convex in both sexes, female frons often with a large, shining, median elevation on lower half; elytral vestiture partly or entirely of scales, except in torus; mostly larger species

- Female frons shallowly to very strongly concave from epistoma to upper level of eyes, male frons weakly to strongly impressed on a much smaller area; elytral vestiture of hair or slender scales; mostly smaller species
2(1). Female frons evenly convex except for a narrow, shallow, transverse impression just above epistoma: some tubercles on male declivity usually larger; larger species3
- Female frons with a large, median, brightly shining elevation on lower half; tubercles on male declivity usually smaller; smaller species ..... 7

3(2). Male declivital interstriae 9 very strongly, acutely elevated, other interstriae each with a conspicuous tubercle at base of declivity forming a rather definite circumdeclivital ring; female scape elaborately ornamented by long hair, longest setae three times as long as club; Arizona to Oaxaca; Quercus; 2.2-2.8 mm

1. lignator Blackman

- Male declivital interstriae 9 weakly elevated, tubercles on other interstriae smaller, not specially oriented; vestiture on female scape usually less well developed. longest setae seldom as much as twice as long as club (some exceptions in lignicolus)
4(3). Costal margin at elytral apex ascending abruptly, eliminating terminal mucro; declivital interstriae 3 weakly elevated, in male armed by a row of pointed tubercles; male interstrial nodules at base of declivity, forming a low, indefinite circumdeclivital row; female scape ornamented by abundant, long hair; Chiapas to Honduras; Quercus; 2.5-3.3 mm

| - | Costal margin at elytral apex descending or horizontal, terminal mucro well developed; declivital interstriae 3 not elevated, granules rounded; pubescence on female scape much less abundant $\qquad$ 5 |
| :---: | :---: |
| 5(4). | Larger; discal striae impressed, interstriae weakly convex; declivital scales less than twice as long as wide; Durango to Hidalgo; Quercus; 3.2-3.3 mm 3. amplinis Wood |
| - | Smaller; discal striae not at all impressed, interstriae almost flat; declivital scales more than four times as long as wide (except male lepidus) $\qquad$ .6 |
| $6(5)$. | Pronotal disc in female with shallow punctures, distinct granules in male; interstrial tubercles on declivity larger in both sexes, smaller toward suture; Durango; Quercus; 2.0-2.4 mm <br> 4. incertus Wood |
| - | Pronotal disc in both sexes, with a few minute granules; declivital scales in male two to four times as long as wide; interstrial granules almost obsolete in female, small in male, of uniform size; Panama; Inga; 2.3-3.0 mm $\qquad$ |

7(2). Elytral vestiture of rather short, coarse, hairlike setae, not flattened, strial setae on declivity much shorter but otherwise similar to those of interstriae; female frontal elevation occupying more than median third on lower two-thirds, all margins declivous but none sharply defined; strial punctures fine, shallow; Jalisco, Quercus; 1.8-2.2 mm

- Elytral vestiture of rows of minute, fine, strial hair and rows of longer, flattened, interstrial scales; female frontal elevation abruptly, angulately margined on lower third; strial punctures rather deep, moderately large8

8(7). Female frontal elevation occupying median third, sharply defined on lower half, its sides gradually descending on upper half, almost reaching upper level of eyes; suture 1 reaching middle of antennal club; scape narrowly triangular, elaborately ornamented by abundant, long hair; male interstriae near declivity each with two to four rather large, rounded nodules; Durango to Oaxaca; Quercus; 2.1-2.7 mm

- Female frontal elevation ovate, occupying slightly less than median third on lower half, sharply, angulately defined on all sides; suture 1 more broadly arched, not reaching middle of club; scape broadly triangular, almost quadrate, much less elaborately ornamented by long hair; male discal interstriae with a few fine granules near declivital base; Puebla; 1.9-2.4 mm 8. ovatus Wood
$9(1)$ Lower frons in both sexes smooth to epistomal margin, a separate epistoma not evident
- Lower frons with a rather conspicuously impressed transverse line between epistomal margin and more or less elevated epistoma (in two species the piece bearing epistomal margin abruptly bent toward mandibles, line seen with difficulty)
$10(9)$. Female frons bearing a rather dense tuft of short, white hair on median third between epistomal margin and level of antennal insertion; New York and California to Honduras; many hosts; $1.6-2.2 \mathrm{~mm}$ 9. swainei Blackman
- Female frons smooth, shining, and glabrous on median third below level of antennal insertion, a few setae often present in lateral areas near epistoma

11(10). Female frons rather deeply, more extensively excavated; female scape more broadly triangular, distance from pedicel insertion to base greater than to apex

> of extension; strial and interstrial punctures larger, impressed, discal interstriae subrugose; Chiapas to Costa Rica; Calliandra, Salix; 2.2-2.8 mm .......................
10. grandis Schedl

- Female frons less strongly excavated; scape narrowly triangular, distance from pedicel insertion to apex of extension greater than to base; strial and interstrial punctures minute, interstriae almost smooth 12
12(11). Female frons toward epistoma moderately protuberant on median third, this area smooth, shining, areas lateral to it minutely reticulate-granulate; anterior margin of female pronotum armed by eight or more small teeth; setae on female vertex short; Chihuahua to Chiapas; 1.8-2.3 mm

11. detentus Wood

- Female frons not protruding on median third, smooth and shining on more than median half; anterior margin of female pronotum unarmed, an occasional small tooth sometimes present; setae on female vertex very long; Costa Rica to Panama; Rheedia; $1.6-2.1 \mathrm{~mm}$

12. carinulus Wood

#### Abstract

13(9). Female frons less strongly, less extensively excavated, its surface reticulate to reticulate-granulate with fine granules; female epistomal process not forming a sharp margin of concavity, narrow marginal piece between epistomal process and epistomal margin in same plane as lower area of concavity; male interstrial setae either hairlike or scalelike

- Female frons rather deeply, extensively excavated to well above eyes, its surface reticulate, with fine punctures, devoid of granules; lower third of female frontal excavation with an additional, shallowly concave area; female epistomal process forming an acute margin of concavity, narrow marginal piece between this process and epistomal margin bent at an abrupt angle to surface of concavity; male interstrial setae on declivity scalelike
14(13). Female frons on or immediately above epistomal processes bearing a conspicuous median elevation ..... 15
- Female frons devoid of a median elevation above epistomal process ..... 16
15(14). Epistomal process in both sexes extended into a large, pointed, median tu-bercle; elytral vestiture of coarse, pointed setae; Michoacán; 2.1-2.7 mm

13. unicornis Wood

- Elevation above epistoma large, transversely folded or ridged, in female only; interstrial setae of blunt scales; Guatemala; 2.0-2.5 mm

14. inimicus Wood

16(14). Strial punctures rather coarse, moderately deep, interstriae about twice as wide as striae; Michigan, E Kansas, and Mississippi to Pennsylvania and Virginia; 2.1-2.5 mm
15. suturalis LeConte

- Strial punctures small, shallow, interstriae about four or more times as wide as striae; epistomal area of female frons virtually glabrous; body more slender, less brightly shining; Chiapas to Honduras; Calliandra, Celtis; 1.7-2.3 mm ........ 16. festivus Wood

17(13). Female frontal excavation with rather numerous, very shallow, small punctures obscurely indicated; female impression just above epistoma shallow, less well defined; anterior margin of female pronotum finely serrate; strial punctures small; interstriae smooth, shining; Arizona; Salix; 1.9-2.5 mm
17. carinulatus Wood

- Female frontal excavation devoid of punctures; female impression just above epistoma abrupt, deeper; anterior margin of female pronotum unarmed; strial punctures minute; interstriae minutely subrugose, subshining; Puebla; Salix; $2.2-2.8 \mathrm{~mm}$

18. tribulatus Wood

## 1. Micracis lignator Blackman

Figs. 145, 146
Micracis lignator Blackman, 1928, New York St. Coll. For., Svracuse, Tech. Pub. 25:195 (Holotype, female; Tucson, Arizona; (U.S. Nat. Mus., 27134)
Micracis truncatus Wood, 1956. Canadian Ent. 88:152 (1)olotype, female; 17 km NE Jacala, Hidalgo, Mexico: Snow Ent. Mus., Univ. Kansas); Wood, 1973. Great Basin Nat. 33:178. Synonymy

Diagnosis.- This distinctive species in the male has a circumdeclivital row of interstrial tubercles resembling that of some Hylocurus species, with no denticles on the convex declivital face; female frons convex and antennal scape rather elaborately ornamented by long hair.

Female.- Length 2.6-2.8 mm (male $2.2-2.7 \mathrm{~mm}$ ), 3.2 (male 2.9) times as long as wide; color very dark brown.

Frons weakly convex, a feeble, transverse impression just above epistoma; surface reticulate, more coarsely so in upper and lateral areas, a few minute granules above; vestiture sparse below, of abundant, coarse, moderately long setae across area above upper level of eyes. Antennal scape moderately long, rather broadly triangular, extension shorter than distance from pedicel insertion to base, bearing numerous long setae, those at apex of extension more than twice as long as club.

Pronotum 1.25 times as long as wide; sides very feebly arcuate and almost parallel on more than basal half, rather broadly rounded in front: anterior margin or submargin irregularly, finely serrate; summit anterior to middle; anterior area asperate; posterior area rugose-reticulate, dull, a few minute, shining granules toward summit. Vestiture of sparse, elongate scales.

Elytra 2.0 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal three-fourths, rather broadly rounded behind except apex strongly acuminate; striae not impressed, punctures fine; interstriae shining, minutely irregular, three times as wide as striae, punctures fine, obscure. Declivity steep, convex, apex produced; striae moderately impressed, punctures slightly larger, deeper; interstriae convex, punctures confused, almost as large as those of striae. Vestiture of rows of minute strial hair and rows of erect interstrial scales; each scale about three to five times as long as
wide, slightly shorter than distance between rows.

Male. - Similar to female except frons more strongly convex, with granules over most of its surface; scape weakly triangular, its vestiture greatly reduced; anterior margin of pronotum coarsely serrate; strial punctures slightly larger, interstrial punctures larger, feebly granulate; each interstriae with a strong nodule at base of declivity forming a circumdeclivital ring, interstriae 9 on declivity strongly elevated, apically joining costal margin; declivital interstrial punctures larger, deeper; declivital scales much larger, broader.

## Distribution.- Arizona to Oaxaca.

USA: Arizona: Tucson, Hopk. US 670c, Quercus, Chrisman; Miller Canyon. Huachuca Mts., 22-V1ll-58. Qucrcus, S. L. Wood. MEXICO: Durango: 4 km E El Palmito, 15-V1-71, Quercus, D. E. Bright. Hidalgo: 17 km NE Jacala, 22-V1-53, 1700 m , Quercus. S. L. Wood; 16 km E Pachuca, 10-V1-67, 2700 m , No. 6, Quercus, S. L. Wood; 8 km W Tulancingo, 11-Vl-67, 2400 m , No. 11, Qucrcus, S. L. Wood. Oaxaca: 51 km SE Nochixtlán, 16-VI-67, No. 51, Quercus, S. L. Wood. Querétaro: 16 km E Landa de Matamoros, 11-V1-71, 1400 m, at light. D. E. Bright. Tlaxcala: km 41 Apizaco-Mexico Highway. 9-11-80.

Hosts.- Quercus sp.
Biology.-As described for the genus.
Notes.- The above treatment was based on the holotype, on 11 other specimens from Arizona, and 57 from Mexico. As the disjunct distribution suggests, there are small consistent differences between specimens from the two areas; for example, males from the southern area have slightly larger nodules in the circumdeclivital ring, and the elytral disc is smoother in both sexes, etc. In all cases the differences are in the degree of development of a character, not in the kind of characters exhibited.

## 2. Micracis lignicolus Wood

Micracis lignicolus Wood, 1969. Brigham Young Univ. Sci. Bull.. Biol. Ser. 10(2):41 (Holotype, male: Cerro Peña Blanca, Morazán, Honduras: Wood Coll.)
Diagnosis.- This species is distinguished from lignator Blackman by the less strongly elevated interstriae 9 at the base of the male declivity, and by the less strongly tuberculate interstriae at the margin of the declivity, by the slightly elevated, subserrate, male declivital interstriae 3 on the basal third, by the
different arrangement of setae on the female frons and scape, and by the narrower interstrial scales in both sexes.

Male.- Length $2.5-3.3 \mathrm{~mm}, 2.8$ (female 3.2) times as long as wide; color reddish brown.

Frons convex above, transversely impressed on lower half, epistomal margin slightly elevated; surface reticulate-granulate. with sparse, smooth granules on convex area; vestiture sparse, limited to lateral areas. Scape about twice as long as pedicel, distal width equal to length, bearing a small tuft of long hair; club 1.8 times as long as wide, suture 1 extending three-fifths of club length from base.

Pronotum 1.1 times as long as wide; sides almost straight and parallel on basal half, weakly constricted just in front of middle, anterior margin rather broadly rounded and armed by 12 teeth; summit at middle, broad; posterior areas reticulate-granulate, punctures fine, inconspicuous, some minutely granulate; vestiture consisting of minute hair and slender scales.

Elytra 1.7 times as long as wide, 1.6 times as long as pronotum; sides straight and parallel on basal three-fourths, narrowly rounded behind; striae moderately impressed on posterior third of dise, punctures rather coarse and deep; interstriae as wide as striae, shining, somewhat irregular, punctures uniseriate, rather fine. Declivity rather abrupt, convex, steep; striae not impressed, punctures smaller and squamiferous; interstriae 1-8 each with one or two rounded nodules at base of declivity, about as in lignator, 9 weakly elevated but elevation ending just behind base of declivity, 3 bearing a row of about six pointed tubercles on upper twothirds, 5 bearing two similar tubercles near base; apex extended slightly but terminated by ascending costal margins that form a pseudoemargination; interstrial punctures coarse, two-thirds as large as those of striae, squamiferous. Vestiture consisting of minute strial hair and interstrial rows of slender, erect scales on disc; on declivity strial setae and some interstrial setae form moderately short scales, each about four times as long as wide, other erect, interstrial scales in rows, much longer at declivital base, some more than twice as long as ground scales.

Female.- Similar to male except 3.2 times as long as wide; frons convex to epistoma, median half glabrous, devoid of granules: scape triangularly extended, bearing a much larger tuft of hair, but shorter than in lignator: striae not impressed toward declivity; declivity devoid of tubercles or nodules, 3 weakly convex; vestiture less dense on declivity, scales more slender, not longer than on disc.

Distribution.- Chiapas to Honduras.
MEXICO: Chiapas: 13 km NE San Cristóbal, 15-V-69, Quercus, D. E. Bricht. GUITEMALA: Voléán de Agna, 19-V'64, 1000 m . No. 598, S. L. Wood. HONDURAS: Cerro Peña Blanca. Morazán, 23-15-64, 2000 m, No. 529 in Micomia schlectendalii, No. 533 in Guercus williamsi, S. L. Wood; Zamorano, Morazán, 1S-IV-64, 700 m, No. 539. Ouercus sapotac folla, S. L. Wood.

Hosts.-Miconia schlectendalii, Qucrcus sapotacfolia, and Q. rilliamsi.

Biology. - As described for the genus.
Notes.- The above treatment was based on the type series of 57 specimens and on one other specimen; 44 additional specimens from the Chiapas series are in the Canadian National Collection.

## 3. Micracis amplinis Wood

Micracis amplinis Wood, 1971. Brigham Young Univ: Sci. Bull., Biol. Ser. $15(3): 25$ (Holotype, male: 5 km W El Salto, Durango, Mexico; Wood Coll.)
Diagnosis.- This is the largest species in the genus; it is also distinguished from all other representatives of the genus by the moderately impressed discal striae, and by the very broad interstrial scales on the declivity.

Male.-- Length 3.2-3.3 mm, 3.0 times as long as wide; color reddish brown.

Frons convex, with a moderate, transverse impression just above epistoma; surface finely reticulate-granulate, with rather numerous large, low, rounded granules widely distributed on convex area; epistomal area smooth, shining; glabrous except for a few setae lateral to epistoma. Antennal scape only slightly flattened; suture 1 reaching middle of club.

Pronotum 1.03 times as long as wide; widest on basal third, sides weakly arcuate, slightly constricted on anterior third, rather broadly rounded in front: anterior margin armed by 10 coarse serrations; summit in front of middle; anterior area coarsely
serrate; posterior area reticulatesubgranulate, dull, a few small, shining granules to base. A few stout setae in lateral areas.

Elytra 1.8 times as long as wide, 1.8 times as long as pronotum; sides almost straight and parallel on basal three-fourths, strongly, acutely acuminate and mucronate behind; striae impressed except on basal fourth, punctures moderately small, deep; interstriae shining, almost smooth, three times as wide as striae, punctures very minute, almost obsolete, each with two or three large granules at base of declivity. Declivity rather steep, convex, apex produced; entire surface minutely granulose; strial punctures small, deep; interstriae 1 and 3 weaklý elevated, punctures on all interstriae as large as those of striae, confused, deep. Vestiture confined to declivity (possibly abraded on disc), of large interstrial scales; each scale about as wide as long, a few as wide as an interstriae.

Distribution.- Durango to Hidalgo and Morelos.

MEXICO: Durango: 5 km W El Salto, 7 -VI-65, 2500 m . No. 41, Qucras, S. L. Wood. Hidalgo: 7 km E Tlahuelumpa, Zacualtipan, I6-N-80, 2050 m , Quercus, T. H. Atkinson. Morelos: Xochimilco, X-1979, Quercus, T. 11. Atkinson.

Biology.- As described for the genus.
Notes.- The above treatment was based on the type series of 2 specimens and on six other specimens.

## 4. Micracis incertus Wood

Micracis incertus Wood, 197I, Brigham Young Univ. Sci. Bull., Biol. Ser. I5(3):26 (Holotype, female; 37 km W Durango, Durango. Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from lepidus Wood by the presence of a few shallow punctures on the pronotal dise, by the larger interstrial tubercles on the declivity, and by the distribution.

Female.- Length $2.0-2.4 \mathrm{~mm}, 3.0$ times as long as wide; color very dark brown.

Frons convex, a moderate, transverse impression just above epistoma; surface finely reticulate-granulate, dull, upper half with rather abundant, shallow punctures of moderate size; a few stout setae in lateral and epistomal areas. Antennal scape moderately triangular, ornamented by rather abundant,
long hair; suture 1 not quite reaching middle of club.

Pronotum 1.1 times as long as wide, as in amplinus except moderately large, shallow, rather abundant punctures intermixed with shining granules on disc. Vestiture of sparse scales and minute hair.

Elytra 1.8 times as long as wide, 1.7 times as long as pronotum; outline as in amplinis; striae not impressed, punctures moderately large; interstriae shining, subrugose, twice as wide as striae, punctures moderately large; uniseriate, anterior margins finely granulate. Declivity steep, convex, apex produced; surface dull; strial punctures small, deep, reduced toward apex; interstrial punctures on 1 and 2 fine, irregular and reduced on lower half, on 3 and lateral areas moderately large, rounded. Vestiture of rows of interstrial scales, largely abraded on disc, each scale about five times as long as wide, as long as distance between rows.

Male.- Similar to female except frons more strongly convex, punctures replaced by granules; discal interstrial granules smaller except larger near declivity, declivital granules larger, extending to apices of 1 and 2 ; interstrial scales on upper fourth of declivity longer, some six or eight times as long as wide.

Distribution.- Durango.
MEXICO: Durango: 37 km and 64 km W Durango, 4 -VI-65, No. 4 at 2000 m , No. 18 at 2500 m , Quercus, S. L. Wood; 5 km W El Salto, 7 -VI-65, 2500 m , No. 41 , Quercus, S. L. Wood.

## Ноsт.- Quercus sp.

Biology.- As described for the genus.
Notes.- The above treatment was based on the type series of eight specimens.

## 5. Micracis lepidus Wood

Micracis lepidus Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2): 4 I (Holotype, female; Cerro Punta, Chiriquí, Panama; Wood Coll.)
Diagnosis.- This species is not closely related to any species known to me, although there may be a remote relationship to lignator Blackman. The size, scalelike elytral setae, armed anterior margin of the female pronotum, and the unexcavated female frons distinguish it.

Female.- Length 2.3-3.0 mm, 3.2 (male 2.6) times as long as wide; color dark brown to black with white scales.

Frons convex above, somewhat flattened on lower third; surface reticulate and finely punctured above, smooth, shining on lower part of flattened area; vestiture subplumose, erect, rather abundant to vertex except on shining epistomal area, short below, moderately long above. Scape broadly triangular, ornamented by a marginal fringe of long hair; club 1.6 times as long as wide, suture 1 reaching middle.
Pronotum 1.3 times as long as wide; sides almost straight and parallel on basal half, rather broadly rounded in front; anterior margin armed by 12 low teeth; summit in front of middle, distinct; posterior area reticulate-granulate, very minute granules indicated toward summit in median area; vestiture short, of minute hair and slender scales.
Elytra 2.0 times as long as wide, 1.6 times as long as pronotum; sides straight and parallel on basal three-fourths, rather narrowly mucronate behind; striae not impressed, punctures minute; interstriae about four times as wide as striae, undulating slightly and with numerous indefinite points, punctures fine. Declivity steep, convex, confined to posterior fourth; strial and interstrial punctures of equal size, close, confused, rows of minute granules on all interstriae except 1 ; apex obtusely mucronate. Vestiture consisting of minute strial hair and erect scales; scales on dise in interstrial rows, more abundant and confused on declivity, each scale three to four times as long as wide; base of declivity also with several pointed bristles longer than scales, sides with some slender, long hair.

Male. - Similar to female except averaging slightly smaller; 2.6 times as long as wide; frons more strongly convex, not flattened below, surface with many rounded granules; scale less strongly expanded, tuft of hair smaller; teeth on anterior margin of pronotum larger; elytral scales shorter, broader, mostly twice as long as wide, bristles and interstrial hair also scalelike and slightly larger than other scales.

Distribution.- Panama.
PANAMA: Cerro Punta, Chiriquí, 19-X1I-6.3, Nos. 315, 371, 387, 404, Inga, S. L. Wood.

Biology.- This species bred in the bole and larger limbs of standing, partly dying trees up to 15 cm in diameter. The gallery system was as described for the genus.

Notes.- The above treatment was based on the type series of 52 specimens.

## 6. Micracis torus Wood

Micracis torus Wood, 1971, Brigham Young U'niv. Sci. Bull., Biol. Ser. 15(3):26 Holotype, female: Volcán Colima, Jalisco, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from the allied evanescens Wood by the smaller size, by the stout, hairlike elytral setae, and by the absence of a sharply defined lower margin of the female frontal elevation.

Female.- Length $1.8-2.2 \mathrm{~mm}, 3.1$ (male 2.7) times as long as wide; color dark reddish brown.

Frons planoconvex to vertex, median half on lower half elevated and brightly shining, its margins rounded, not sharply defined, remaining area minutely reticulate-gramulate; vestiture fine, short, uniformly distributed on upper area, slightly longer toward vertex. Antenna about as in ecanescens except hair on scape slightly shorter.

Pronotum 1.2 times as long as wide; as in evanescens except reticulation in posterior areas finer.

Elytra 1.8 times as long as wide, 1.4 times as long as pronotum; outline as in evanescens; striae not impressed, punctures small. shallow; interstriae about three times as wide as striae, almost smooth, punctures very fine, uniseriate. Declivity steep, convex, apex produced; strial punctures reduced, obscure; interstrial punctures small, indistinct. Vestiture of rows of fine, short, strial hair, and rows of longer, coarse, pointed, interstrial hair; slightly longer on declivity, longest interstrial setae equal in length to distance between rows, all setae somewhat confused on declivity.

Male. - Similar to female except body stouter; frons convex; a transverse impression on lower third, elevation absent, surface with several rounded granules.

Distribution.- Jalisco.
MEXICO: Jalisco: Volcán Colima 23-V1-65, 2500 m . No. 102, leguminous tree, S. L. Wood.

Biology.- As described for the genus. The host was a leguminous tree with bipinnately compound leaves.

Notes.- The above treatment was based on the type series of 19 specimens.

## 7. Micracis cvanescens Wood Fig. 146

Micracis ctanescens Wood, 1956. Canadian Ent. 88:152 (Holotype, female; 45 km SW El Salto, Durango, Mexico; Snow Ent. Mus., Univ. Kansas)
Diagnosis.- This species is distinguished from the closely allied ovatus Wood by the larger size, by suture 1 reaching the middle of the antennal club, and by the much larger, female, frontal elevation, which is not sharply defined above.

Female. - Length 2.1-2.7 mm, 3.2 (male 2.8) times as long as wide; color reddish brown.

Frons weakly convex, with central half occupied by a large, low, smooth, shining elevation, its margins on upper two-thirds descending gradually, abruptly margined on lower third; surface at sides and above reticulate, several isolated granules above; vestiture of coarse setae in marginal areas, longer and more abundant above. Antennal scape narrowly triangular, distance from pedicel insertion to apex of extension almost as long as basal portion, elaborately ornamented by abundant, very long hair; suture 1 reaching middle of club.

Pronotum 1.2 times as long as wide; sides almost straight and parallel on more than basal half, rather broadly rounded in front; anterior margin finely serrate; posterior area reticulate-subgranulate, a few shining granules behind summit. Vestiture of sparse scales.

Elytra 2.0 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal three-fourths, strongly acuminate and mucronate behind; striae not impressed, punctures moderately small; interstriae almost rugose, twice as wide as striae, punctures rather small, uniseriate. Declivity steep, convex, produced at apex; surface granulose, dull; strial punctures reduced in size and depth toward apex; interstrial punctures feebly granulate on 1 and 2 , more strongly granulate on 3 and lateral areas. Vestiture of rows of interstrial scales, strial
hair almost never visible; each scale about four to six times as long as wide, longest about equal in length to distance between rows.

Male.-Similar to female except slightly stouter and smaller; frons more strongly convex, granules larger and more widely distributed, elevation absent; scape weakly triangular with few setae; 10-12 teeth on anterior margin of pronotum larger; declivital granules and scales very slightly larger.

Distribution.- Durango to Oaxaca.
MEXICO: Durango: 48 km SW El Salto, 23-VII-53, 2500 m . Michoacán: 33 km W Morelia, 16-VI-65, 2200 m, No. 65, 29 km W Quiroga, I7-VI-65, 2200 m, No. 73. Oaxaca: 51 km SE Nichixtlán, 5 -VII- $53,2300 \mathrm{~m}$. Sinaloa: 32 km NE Copala, 22-VII-53, 1900 m . All from Qucreus, by me.

## Hosts. - Quercus spp.

Biology.- As described for the genus.
Notes.- The above treatment was based on 6 paratypes and on 36 other specimens.

## 8. Micracis oratus Wood Fig. 146

Micracis otatus Wood, 1956, Canadian Ent. 88:150 (Holotype, female; 8 km NE Teziutlan, Puebla, Mexico; Snow Ent. Mus., Univ. Kansas)
Diagnosis.- This species is distinguished from the allied ceanescens Wood by characters summarized in the above key and in the diagnosis of that species.

Female.- Length 1.9-2.4 mm, 3.5 (male 3.0) times as long as wide; color reddish brown.

Frons as in cvanescens except elevation smaller, higher, occupying less than median third on lower half, its outline ovate, sharply margined on all sides, its summit flat, smooth, shining. Antennal scape broadly triangular, ornamented by long hair; suture 1 not reaching middle of club.

Pronotum 1.35 times as long as wide; about as in cvanescens except posterior areas more finely reticulate; sparse, short vestiture hairlike.

Elytra 2.3 times as long as wide, 1.7 times as long as pronotum; as in evanescens except discal interstriae more nearly smooth and interstrial punctures near declivity granulate; declivital surface obscurely reticulate, interstrial granules on 1 and 2 slightly larger.

Male.-Similar to female except slightly smaller, stouter; frons convex, finely

granulate, elevation reduced to a very small epistomal elevation; eight rather coarse teeth arm anterior margin of pronotum; scales on declivity distinctly longer.

Distribution.- Puebla.
MEXICO: Puebla: 8 km Ne Teziutlán, 27-VI-53, 2-VII-67, 1600 m , No. 146, S. L. Wood.

Biology.- As described for the genus. Both series were taken from broken branches of an unidentified tree.

Notes. - The above treatment was based on 24 paratypes and on 10 other specimens.

## 9. Micracis swainei Blackman

Figs. 146, 148-150

Micracis swainci Blackman, 1920, Mississippi Agric. Expt. Sta. Tech. Bull. 9:32 (Lectotype, female; Juka, Mississippi; U.S. Nat. Mus., 24735, designated by Wood, 1973. Great Basin Nat. 33:178)
Micracis populi Swaine, 1920, in Blackman, Mississippi Agric. Expt. Sta. Tech. Bull. 9:3] (Holotype, female: Ithaca, New York; Canadian Nat. Coll., 154); Wood, 1957, Canadian Eut. 89:399. Synonymy
Micracis robustus Schedl, 1948, Rev. de Ent. 19:576 (Holotype, male; Esmeralda, Chiapas, Mexico; Schedl Coll.); Wood, 1974, Great Basin Nat. 34:283. Synonymy
Micracis pygmacus Schedl, 1948, Rev. de Ent. 19:577 (Holotype, male; Huehuetán, Chiapas, Mexico: Schedl Coll.): Wood, 1974, Great Basin Nat. 34:283. Synonymy
Micracis photophilus Wood, 1956, Canadian Eut. 88:149 (Holotype, female: El Salto, San Luis Potosí, Mexico; Snow Ent. Mus., Univ. Kansas); Wood. 1973, Great Basin Nat. 33:178. Synonymy
Diagnosis. - This species evidently is distinguished from festivus Wood by the presence of a distinct tuft of pale hair on the female epistoma and by other characters noted in the above key.

Female.- Length $1.6-2.2 \mathrm{~mm}, 3.2$ (male 2.7) times as long as wide; color yellowish brown.

Frons strongly impressed, shallowly concave from epistoma to upper level of eyes; surface reticulate-subrugose, with fine granules above; epistoma with a dense tuft of moderately long yellowish hair, a few setae on marginal areas above. Antennal scape narrowly triangular, bearing numerous long setae; suture 1 not attaining middle of club.

Pronotum 1.3 times as long as wide; as in suturalis LeConte except anterior margin unarmed by serrations, posterior area more finely sculptured. Sparse vestiture hairlike.

Elytra 1.9 times as long as wide, 1.4 times as long as pronotum; outline as in suturalis; striae not impressed, punctures small, shallow; interstriae smooth, shining, punctures very fine. Declivity steep, convex, apex produced; surface shining, granulate at apex; strial punctures deeper; interstriae about equally, rather finely granulate. Vestiture of moderately coarse hair.

Male-- Similar to female except slightly smaller, stouter; frons convex on upper twothirds, granules on convex area; anterior margin of pronotum armed by eight coarse teeth; punctures on discal interstriae finely granulate; elytral vestiture slightly longer.

Distribution.-S California, S Ontario, and New York to Florida, Texas, and Honduras.

CANADA: Ontario (Port Colborne). USA: S California, District of Columbia, Florida, Ceorgia, E Kansas. Lonisiana, Maryland, Mississippi, New York, Pennsylvania, Temnessee, Texas, West Virginia. MEXICO: Chiapas, Jalisco, Nayarit, San Luis Potosí, Sinaloa, Veracruz. HONDURAS: Morazán (Zamorano).

Hosts.- Baccharus sp., Celtis iguanae, Cercis canadensis, Inga sp., Miconia sp., Populus sp., Salix spp., Trichlia arborea, etc.

Biology.- As described for the genus.
Notes.- The above treatment was based on the lectotype of swainei, on the holotypes of populi, robustus, and photophilus, and on 571 other specimens. The manuscript name mexicanus Schedl has appeared in the literature as a nomen nudum in references to this species.

The material south of central Texas has smaller strial punctures, coarser elytral hair, coarser frontal hair, and the female frontal impression does not reach the upper level of the eyes as it does in specimens from the eastern United States. These characters appear to change on a gradual clinal gradient and do not clearly distinguish geographical races.

## 10. Micracis grandis Schedl

Micracis grandis Schedl, 1948, Rev. de Ent. 19:575 (Holotype, female: San José de Ixtepec, Chiapas, Mexico; Schedl Coll.)
Micracis costaricensis Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):39 (Holotype, female; Volcán Poas, Heredia, Costa Rica; Wood Coll.); Wood, 1974, Great Basin Nat. 34:283. Synonymy
Diagnosis.- This species may be distinguished from the allied detentus Wood and
carinulus Wood by characters summarized in the above key.

Female.- Length 2.2-2.8 mm, 3.2 (male 2.8) times as long as wide; color rather dark reddish brown.

Frons strongly, transversely impressed and slightly concave from epistoma to well above eyes, upper half of impressed area with a fine, low, median carina; surface coarsely reticulate except smooth just above epistoma; vestiture consisting of sparse, short setae in reticulate area, with a fringe of long subplumose hair along margin of impressed area above level of eyes. Scape flattened, triangular, ornamented by a fringe of long hair; sutures of club strongly procurved, 1 reaching middle, 2 extending three-fourths of club length from its base.

Pronotum 1.3 times as long as wide; widest on basal half, sides almost straight and parallel on slightly more than basal half, rather broadly rounded in front; anterior margin armed by 12 rather coarse, isolated teeth; summit in front of middle; rather coarsely reticulate behind summit with rather sparse, fine, subgranulate punctures. Vestiture consisting of rather short, stout, delicate white setae.

Elytra 1.9 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal three-fourths, rather broadly rounded behind to short, projecting sutural apex; striae not impressed, punctures small, shallow, distinct; interstriae about three times as wide as striae, irregular, punctures and other features obscured by irregular surface features. Declivity evenly convex, very steep; striae slightly impressed, punctures deeper than on disc; interstriae weakly convex, with lower half of 2 somewhat impressed; all interstriae bearing median rows of fine, rounded granules, those in lateral areas a little larger; terminal mucro as in other species of this genus. Vestiture consisting of rows of fine strial hair and delicate, very slender interstrial scales of equal length; each scale almost equal in length to distance between rows of scales; easily abraded.

Male.-Similar to female except slightly smaller, 2.4 mm , stouter, 2.8 times as long as wide; frons convex with a slight transverse impression just above epistoma, surface finely granulate, vestiture greatly reduced; scape
not dilated, tuft of hair almost obsolete; pronotum and elytra very slightly more coarsely sculptured.

Distribution.- Chiapas to Costa Rica.
MEXICO: Chiapas: San José de Ixtepec. HONDURAS: Zamorano, Morazán, 18-IV-64, 700 m , No. 559 , Salix guatemalensis, S. L. Wood. COSTA RICA: Volcán Poas, Heredia, 19-VI-66, 2000 m, No. 7 , leguminous shrub, S. L. Wood: Santa Ana, San José, 4-X-63, 1400 m . No. 226. Calliandra confusa, S. L. Wood; San Ignacio de Acosta, San José, 5-VII-63, 1500 m , No. 25, Calliandra confusa, S. L. Wood: Tapantí, Cartago, 17-VIII-63, 1400 m, No. 102, Calliandra confusa, S. L. Wood.

Hosts.- Calliandra confusa, and Salix guatemalensis.

Biology. - As described for the genus.
Notes. - The above treatment was based on the holotype of grandis, on 89 specimens in the type series of costaricensis, and on 11 other specimens.

## 11. Micracis detentus Wood

Micracis detentus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. $10(2): 42$ (Holotype, female; 24 km S Mazamitla, Jalisco, Mexico; Wood Coll.)
Diagnosis.- This species is very closely related to carinulus Wood, but it may be distinguished by the larger size, by the larger granules behind the pronotal summit, by the more deeply impressed female frons with a more prominent median elevation below, and by the coarser interstrial bristles on the declivity.

Female.- Length $1.8-2.3 \mathrm{~mm}, 3.2$ (male 2.7) times as long as wide; color yellowish brown.

Frons transversely, subconcavely impressed from epistoma to upper level of eyes, median third of epistoma moderately elevated, smooth, impunctate, shining elevation extending about one-third of distance to upper level of eyes; remaining surface reticulategranulate, punctures minute, obscure; vestiture of minute subplumose hair, becoming longer toward upper margin of impression. Scape narrowly triangular, ornamented by a tuft of long hair; club 1.7 times as long as wide, suture 1 extending slightly beyond middle.

Pronotum 1.3 times as long as wide; sides straight and parallel on slightly more than basal half, rather broadly rounded in front; anterior margin unarmed; summit in front of middle; posterior area reticulate-granulate,
with rather sparse, fine, isolated granules; vestiture hairlike, inconspicuous.

Elytra 2.0 times as long as wide, 1.6 times as long as pronotum; sides straight and parallel on basal three-fourths, acuminate behind; striae not impressed, punctures small, distinct; interstriae at least twice as wide as striae, with lines and points, punctures uniseriate, very fine. Declivity steep, convex, confined to posterior fourth; surface minutely granulose, strial punctures deeper but somewhat obscure; interstrial punctures replaced by fine granules; apex rather strongly acuminate. Vestiture consisting of very fine strial hair and rows of erect, interstrial bristles, slightly longer and coarser on declivity; each bristle on declivity slightly longer than distance between rows.

Male.-Similar to female except 2.7 times as long as wide; frons convex above, a moderate transverse impression on lower half, median elevation obsolete; scape not as wide as long, bearing a small tuft of shorter hair; anterior margin of pronotum armed by eight teeth; declivital vestiture slightly coarser.

Distribution.- Chihuahua to Chiapas.
Mexico: Chiapas: 13 km N Ocosingo, 2-Vi-69, Salix, D. E. Bright. Chihuahua: Maguarichic, 13-V1I-60, at light, S. L. Wood. Jalisco: 8 km S Atenquique, 25-V1-65, 1000 m , No. 118, shrub, S. L. Wood; 24 km S Mazamitla, 22-VI-25, 2500 m , No. 94, leguminous tree, S. L. Wood.

Host.- Salix sp., etc.
Biology.- As described for the genus.
Notes.- The above treatment was based on the type series of 20 specimens and on 6 other specimens.

## 12. Micracis carinulus Wood

Micracis carinulus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):40 (Holotype, female: Playón, Puntarenas, Costa Rica; Wood Coll.)
Diagnosis.- Similar to grandis Schedl, but smaller, the declivital striae not impressed, the impression of the female frons not reaching the upper level of the eyes, with the median carina rather sharply elevated.

Female.- Length $1.6-2.1 \mathrm{~mm}, 3.1$ times as long as wide; color yellowish brown.

Frons broadly concave from epistoma to upper level of eyes, upper half divided by a fine, low carina, surface smooth and shining just above epistoma, then finely punctured and becoming coarsely reticulate on upper
half; vestiture consisting of short, stout, close setae in concave area, and long, curved, subplumose hairs along upper margin of concavity. Antenna as in grandis except wider.

Pronotum as in grandis except anterior margin unarmed.

Elytra as in grandis except surface of dise a little more irregular and strial punctures less distinct. Declivity evenly convex except for terminal mucro; strial punctures very slightly impressed; interstriae with small, rather obscure granules. Vestiture consisting of moderately long, rather abundant, coarse strial and interstrial setae; those on median row of each interstriae slightly longer.

Male.- Similar to female except frons convex and finely granulate, with a slight transverse impression above epistoma; scape less strongly dilated; anterior margin of pronotum armed by about eight small serrations; median rows of elytral setae more nearly scalelike.

Distribution.- Costa Rica and Panama.
COSTA RICA: Playón, Puntarenas, 22-II-64, 50 m , No. 450, Rheedia edulis, S. L. Wood. PANAMA: Ft. Clayton, Canal Zone, 22-XII-63, 30 m , No. 33I, S. L. Wood.

## Нозт.- Rheedia edulis

Biology.-This species was taken from branches $2-6 \mathrm{~cm}$ in diameter. The galleries were as described for the genus.

Notes. - The above treatment was based on the type series of 22 specimens.

## 13. Micracis unicornis Wood

Micracis umicomis Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):42 (Holotype, male; 6 km W Quiroga, Michoacán, Mexico; Wood Coll.)
Diagnosis.- This unique species evidently is somewhat allied to inimicus Wood, although the relationship appears remote. It is distinguished by the large, pointed epistomal tubercle in both sexes, and by other characters mentioned in the above key.

Female.- Length 2.1-2.7 mm, 3.2 (male 2.9) times as long as wide; color dark reddish brown.

Frons moderately concave from epistoma to slightly above eyes; epistoma armed by a large, pointed, median tubercle; surface reticulate, almost subrugose, a few minute granules obscurely indicated in marginal areas; vestiture rather sparse, fine, except longer
toward vertex. Antennal scape rather broadly triangular, rather sparsely ornamented by long hair; suture 1 exceeding middle of club.

Pronotum 1.3 times as long as wide; sides straight and parallel on basal two-thirds, broadly rounded on unarmed anterior margin; posterior area reticulate, with moderately coarse granules almost to base. Vestiture of rather coarse hair.

Elytra 1.9 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal three-fourths, obtusely produced and mucronate behind; striae not impressed, punctures small, shallow, interstriae almost smooth, about three times as wide as striae, punctures fine. Declivity steep, convex, apex acuminately produced; surface obscurely reticulate; strial punctures as large but deeper than on disc; interstrial punctures very finely, obscurely impressed on 1 and 2, more coarsely granulate on 3 and lateral areas. Vestiture of rows of fine, short, strial hair and rows of longer, much coarser, pointed interstrial hair.

Male- Similar to female except very slightly smaller, stouter; frons convex, a rather strong, transverse impression just above epistomal tubercle, a strong median fovea in impression; scape less strongly expanded, 10 teeth arm anterior margin of pronotum.

Distribution.-Michoacán.
MEXICO: Michoacán: 6 km W Quiroga, 17-VI-65, Nos. 67, 72, shrubs, S. L. Wood.

Biology.- As described for the genus.
Notes.- The above treatment was based on the 2 males in the type series and on 30 other specimens.

## 14. Micracis inimicus Wood

Micracis inimicus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2): 42 (Holotype, female: Volcán de Agua, Esquintla, Guatemala; Wood Coll.)
Diagnosis.-Evidently this species is allied to festivus Wood, but it may be distinguished by characters summarized in the above key.

Female.- Length $2.0-2.5 \mathrm{~mm}, 3.5$ (male 2.7) times as long as wide; color medium to dark brown.

Frons broadly concave to upper level of eyes, lower third with unusual sculpture; epistomal margin slightly elevated, smooth
on a narrow band on median fourth, then a slight, narrow ridge, then above this a narrow, transverse, slit-like impression, rather strongly abruptly, transversely elevated above impression on more than median half, upper slope of this elevation marked by two or three minute, transverse ridges in its gradual descent to concavity; vestiture short, sparse, inconspicuous; surface reticulategranulate. Scape narrowly triangular, ornamented by a tuft of long hair; club 1.9 times as long as wide, widest on distal half, suture 1 extending two-thirds of club length from base.

Pronotum 1.3 times as long as wide; as in detentus Wood, except some setae stout, almost scalelike.

Elytra 2.1 times as long as wide, 1.75 times as long as pronotum; outline and disc as in detentus except strial punctures rather obscure. Declivity steep, convex, confined to posterior fourth; striae weakly impressed, punctures larger, deeper; interstrial punctures subgranulate, except reduced on 2; granules larger in some paratypes. Vestiture consisting of very fine strial hair and rows of erect interstrial scales, slightly longer on declivity; each scale on declivity as long as distance between scales, spaced more closely within each row, truncate at their apices, each about five times as long as wide.

Male- - Similar to the female except 2.7 times as long as wide; frons convex, transversely impressed on lower half, epistoma elevated on median third, without elaborate sculpture of female; anterior margin of pronotum armed by six teeth; declivital tubercles more distinct except on interstriae 2 and 3 .

Distribution.- Guatemala.
GUATEMALA: Volcán de Agua, Esquintla. 19-V-64, 1000 m, No. 603, shrub, S. L. Wood.

Biology. - As described for the genus.
Notes.- The above treatment was based on the type series of 23 specimens.

## 15. Micracis suturalis LeConte Figs. 148-150

Micracis suturalis LeConte, 1868, Trans. Amer. Ent. Soc. 2:165 (Lectotype, female; Illinois; Mus. Comp. Zool., 1014, designated by Wood, 1973. Great Basin Nat. 33:179)
Micracis aculeata LeConte, 1868, Trans. Amer. Ent. Soc. 2:165 (Lectotype, male; Virginia; Mus. Comp. Zool., 1013, present designation); Blackman,

1920, Mississippi Agric. Expt. Sta. Tech. Bull. 9:29. Synonymy
Micracis meridiamus Blackman, 1920, Mississippi Agric. Expt. Sta. Tech. Bull. 9:29 (Lectotype, female; Agricultural College, Mississippi; U.S. Nat. Mus., 24733, designated by Wood, 1973. Great Basin Nat. 33:179)
Diagnosis.- Within the species group having an obscure median carina on the upper half of the female frontal concavity, this species is distinguished by the rather coarse strial punctures, by the somewhat larger size, and by the distribution.

Female.- Length 2.1-2.5 mm, 3.2 (male 2.8) times as long as wide; color very dark reddish brown.

Frons broadly, rather shallowly concave from epistoma to above eyes, upper third with an obscure median carina; surface reticulate, almost rugose except shining on median third below level of antennal insertion. Antennal scape broadly triangular, ornamented by abundant, long hair; suture 1 reaching middle of club.

Pronotum 1.2 times as long as wide; sides almost straight and parallel on basal twothirds, rather narrowly rounded in front; anterior margin irregularly armed by about eight small serrations; posterior area reticulate, with a few isolated, small granules.

Elytra 2.0 times as long as wide, 1.6 times as long as pronotum; sides straight and parallel on basal three-fourths, acuminately produced at apex; striae not impressed, punctures moderately fine, impressed; interstriae shining, slightly irregular, less than twice as wide as striae, punctures fine, shallow. Declivity steep, convex, apex produced; surface less shining; strial punctures smaller, deeper; interstriae 1 and 3 weakly elevated, punctures on 1 and 2 feebly granulate, those on 3 and lateral areas larger. Vestiture of rather fine, short strial and interstrial hair.

Male.-Similar to female except slightly stouter; frons convex on upper half, granules on convex area large; scape less strongly flattened, with fewer setae; anterior margin of pronotum more coarsely serrate; interstrial punctures on disc rather finely granulate to base; declivital granules slightly larger; interstrial setae scalelike, each scale about four to six times as long as wide.

Distribution-- Michigan, Kansas, and Mississippi to the Atlantic Coast.

USA: Illinois, Kansas, Maryland, Michigan, Mississippi, Ohio, Pennsylvania, Virginia, West Virginia.

Host.-Cercis canadensis.
Biology.- As described for the genus.
Notes.- The above treatment was based on the syntypes of suturalis, aculeata, and meridianus and on 139 other specimens. It might also be construed that aculeata was based on more than one specimen, because of LeConte's use of "Southern States" instead of Virginia, where the only specimen now in his collection and fitting his description was taken. As the lectotype of aculeata LeConte, I designate the male from "Va." in the LeConte collection and bearing type No. 1013. To my knowledge this male is the only known original specimen; it is designated a lectotype only because LeConte did not state how many specimens were in his series and because he used "Southern States" (plural) instead of Virginia, as indicated on his specimen.

## 16. Micracis festivus Wood

Micracis fcstivus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):43 (Holotype, female; Zamorano, Morazán, Honduras; Wood Coll.)
Diagnosis.- Apparently the only known species allied to this one is inimicus Wood, but it is easily distinguished by the slender elytral setae and by the very different frontal sculpture of the female.

Female.- Length $1.7-2.3 \mathrm{~mm}, 3.4$ (male 2.7) times as long as wide; color dark brown.

Frons concavely impressed from epistoma to above upper level of eyes; epistomal margin elevated, median half with a narrow, slitlike impression just above margin and a low, elevated, transverse, subcarinate ridge immediately above slit; surface reticulate-granulate, punctures fine, obscure; vestiture sparse, fine, short below, longer above. Scape narrowly triangular, ornamented by a tuft of long hair; club 1.6 times as long as wide, suture 1 extending beyond middle.

Pronotum 1.2 times as long as wide; as in detentus Wood except granules in posterior areas larger and anterior margin armed by six small teeth.

Elytra 2.1 times as long as wide, 1.8 times as long as pronotum; outline and dise as in detentus except strial punctures very slightly deeper. Declivity steep, convex, confined to
posterior fourth; striae feebly impressed, punctures deeper and slightly larger than on disc; interstriae each armed by a row of rounded granules similar to but slightly larger than in inimicus; apex strongly acuminate or mucronate. Vestiture consisting of fine strial hair and rows of longer interstrial bristles, slightly longer on declivity; each bristle up to one and one-half times as long as distance between rows of bristles, more closely spaced within each row.

Male.-Similar to female except 2.7 times as long as wide; frons as in male of inimicus; interstrial punctures on disc as large as those of striae, very feebly granulate; strial punctures smaller on disc and declivity, somewhat obscure on declivity; vestiture with interstrial setae on dise rather narrowly scalelike, truncate, those on declivity longer, more slender and almost pointed at their apices.

Distribution.- Chiapas to Honduras.
MEXICO: Chiapas: 13 km N Ocosingo, 2-VI-69. Salix, D. E. Bright. HONDURAS: Zamorano, Morazán, 18-11$64,700 \mathrm{~m}$, No. 506 in Celtis iguanae, No. 534 in Calliandra houstoniana, S. L. Wood.

Hosts.-Calliandra houstoniana, Celtis iguanae.

Biology.-As described for the genus.
Notes.- The above treatment was based on the type series of 32 specimens and on one other specimen.

## 17. Micracis carimulatus Wood

Micracis carinulatus Wood. 1960, Great Basin Nat. 20:62 (Holotype, female; Cave Creek Canyon, Chiricahua Mts., Arizona: Wood Coll.)
Diagnosis.- This species is distinguished from tribulatus Wood by characters summarized in the above key. These two species are unique in having the female frons very strongly excavated and an additional impression just above the epistoma.

Female.- Length 1.9-2.5 mm, 3.2 (male 2.8) times as long as wide; color dark reddish brown.

Frons very strongly impressed, moderately concave from epistoma to vertex, median half of lower third with an additional impression, median line on upper third acutely carinate; surface reticulate, with fine, distinct punctures; epistoma acutely raised at lower limits of concavity, a narrow piece bearing epistomal margin acutely separated from
frontal area; vestiture fine, short, sparse, except very long on vertex. Antennal scape rather broadly triangular, extended portion longer than basal area measured from point of pedicel insertion, with numerous setae; suture 1 not reaching middle of club.

Pronotum 1.3 times as long as wide; as in suturalis except posterior area shining, subreticulate, vestiture of fine and stout setae.

Elytra 2.0 times as long as wide, 1.7 times as long as pronotum; outline as in suturalis; striae not impressed, punctures moderately coarse, rather deep; interstriae one and onehalf times as wide as striae, shining, smooth, punctures fine, feebly granulate. Declivity steep, convex, apex produced; surface subshining; strial punctures slightly smaller; interstrial granules minute on 1 and 2 , moderately large on 3 and lateral areas. Vestiture of rows of minute strial hair and rows of long bristles, some almost scalelike.

Male.-Similar to female except frons moderately convex except for median impression on lower half, epistomal margin as in female; scape much less strongly flattened, sparsely pubescent; anterior margin of pronotum armed by 8-10 coarse teeth; interstrial granules slightly larger on disc and declivity; interstrial scales longer, about eight times as long as wide.

Distribution.- Arizona.
USA: Arizona: Oak Creek Canyon, Coconino Co., 1-VIIl-62, Salix, S. L. Wood; Cave Creek Canyon. Chiricahua Mts., 4 -VIII-60, Salix, S. L. Wood: Sabino Canyon, Pima Co., 6-Vill-68, Salix, D. E. Bright.

Host.- Salix.
Biology.- As described for the genus.
Notes. - The above treatment was based on the type series of 66 specimens and on 16 other specimens.

## 18. Micracis tribulatus Wood

Micracis tribulatus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):40 (Holotype, female: 26 km W Texmelucan. Puebla, Mexico; Wood Coll.)
Diagnosis.- This species is very closely related to carinulatus Wood, from which it is distinguished by characters summarized in the above key and in the following description.

Female.- Length 2.2-2.8 mm, 3.6 (male 2.9) times as long as wide; color very dark brown.

Frons as in carinulatus except punctures not evident, and impression on lower third more abrupt and deeper. Antenna as in $c a-$ rinulatus. Pronotum as in carinulatus except posterior area strongly reticulate, dull. Elytra as in carinulatus except strial punctures very small, interstriae four times as wide as striae.

Male.- Similar to male of carinulatus except pronotal disc more strongly reticulate, dull; strial punctures and interstrial granules on disc much smaller.

Distribution.- Puebla.
MEXICO: Puebla: 25 km W Texmelucan, 13-VI-67, 2900 ml , No. 29, Salix, S. L. Wood.

Biology.-As described for the genus.
Notes.- The above treatment was based on the type series of 11 specimens.

## Genus MICRACISELLA Blackman

Pscudomicracis Blackman, 1920 (December) (nec Eggers, 1920), Mississippi Agric. Expt. Sta. Tech. Bull. 9:20 (Type-species: Micracis opacicollis LeConte, original designation)
Micracisella Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Bull. 25:192. Replacement name
Diagnosis.- This genus is closely related to Micracis LeConte and, although it is not easily characterized, biologically it is very distinct. From Micracis it is distinguished by the smaller size of most species, by the emarginate eyes, by the extremely large eyes of several species, by the stouter antennal club with sutures 1 and 2 more broadly arched, suture 1 never exceeding the middle of the club, by the poorly developed, often divaricate sutural apex of the elytra, and by the presence of at least one tooth on the outer apical margin of the protibia. The frontal vestiture is one of the most distinctive generic characters; also the antennal scape is short, and feebly if at all flattened in either sex.

Description.- Length $1.2-2.5 \mathrm{~mm}$, 2.8-3.2 times as long as wide; color yellowish brown to black.

Frons usually sexually dimorphic, female convex to shallowly concave, impression usually less pronounced, less extensive or sculpture coarser in male, frontal vestiture short to moderately long, not abundant or uniquely arranged. Eye emarginate, varying from normal to exceedingly large and coarsely faceted. Antennal scape short, not flattened, ornamented by a large tuft of hair in female, a small tuft in male; funicle 6 -segmented; club about one and one-half times as long as wide, two sutures clearly indicated by setae, suture 1 never extending beyond middle of club. Pronotum rather conservatively sculptured, anterior margin armed by two to six teeth. Scutellum present. Elytra elongate, weakly striate, apex slightly produced, usually not clearly mucronate in any species, weakly divaricate in some. Anterior tibiae moderately flattened, with five subapical teeth, at least one of these on lateral margin.

Distribution.- United States to Colombia; 20 species are known from North and Central America, one of which also occurs in Colombia.

Biology.- All species breed in cut, broken, or dying twigs smaller than 1 cm in diameter. The beetles are monogamous. The male constructs the entrance tunnel and a small pith cavity. The pith tunnel is extended in both directions by the female; a few eggs are deposited along its margins, evidently in indefinite niches. The larvae extend the pith tunnel in congress, often entirely consuming the available pith. A pair of adults rarely produces more than a dozen offspring.

## Key to the Species of Micracisella

1. Anterior margin of pronotum armed by four (six in adnata) teeth; elytral apex usually more acutely mucronate; eyes commonly elongate, often very narrowly separated below

- Anterior margin of pronotum armed by two basally contiguous teeth (widely separated in squamatula); elytral apex commonly weakly to strongly devaricate, mucro usually absent; eyes usually shorter, more widely separated below
2(1). Eyes rather finely faceted, little more than twice as long as wide, separated below by a distance at least as great as width of an eye ..... 3
- Eyes very coarsely faceted, about three times as long as wide, very narrowly separated below by a distance less than half width of an eye ..... 9

3(2). Declivital interstriae 2 devoid of granules, 3 and usually 1 uniseriately
granulate and/or slightly elevated; larger species except subnitida ...................... 4

- Declivital interstriae 2 similar in sculpture to 1 and 3, each with a row of small granules; smaller species

4(3). Anterior margin of pronotum armed by six teeth; declivital interstriae 3 not at all elevated; interstrial scales on declivity less than three times as long as wide; Veracruz; Quercus; 1.9-2.0 mm

1. adnata Wood

Anterior margin of pronotum armed by four teeth (six in mimetica); declivital interstriae 3 distinctly, rather weakly elevated or not; interstrial scales on declivity more than six times as long as wide

5(4). Declivital interstriae 3 very feebly elevated; frons weakly, transversely impressed on lower third, several conspicuous granules on upper area, pubescence inconspicuous; elytral vestiture shorter, more slender, not conspicuously different on declivity; Arizona, New Mexico; 1.7 mm
2. subnitida Blackman

- Declivital interstriae 3 distinctly elevated; frons without an evident impression, vestiture rather abundant; elytral vestiture longer, broader, conspicuously longer on declivity

6(5). Upper two-thirds of frons with about 30 granules; elytral scales shorter, broader; denticles on declivital interstriae 3 smaller to obsolete; Oaxaca; mistletoe on Quercus; 2.3-2.4 mm
3. mimetica Wood

- Upper frons without granules; elytral scales longer, more slender; declivital interstriae 3 more coarsely serrate; Arizona to Michoacán and Hidalgo; Quercus; $2.0-2.5 \mathrm{~mm}$

4. knulli (Blackman)

7(3). Declivital striae deeply impressed; strial punctures on disc rather coarse, each puncture with its central point elevated, giving appearance of an eye; Oaxaca; Arbutus; 1.9-2.3 mm
5. ocellata Wood

- Declivital striae not impressed; strial punctures on disc smaller, normally concave8

8(7). Strial punctures very small, shallow, interstriae more than twice as wide as striae; interstrial scales about four to six times as long as wide; Michoacán and Puebla to Chiapas; Arbutus, Rubus; 1.7-2.2 mm

- Strial punctures moderately large, distinctly impressed, interstriae as wide as striae; interstrial scales about three times as long as wide; Veracruz; Quercus; 1.5 mm

7. scitula Wood

9(2). Strial punctures small, but distinctly larger, impressed; interstrial punctures on declivity smaller than those of striae, obsolete in some females, devoid of granules; Chiapas to Honduras; $1.4-1.8 \mathrm{~mm}$ 8. hondurensis Wood

- Strial punctures minute, shallow; strial and interstrial punctures on declivity rather deeply impressed, subequal in size 10

10(9). Declivital interstriae devoid of granules; scales on declivital interstriae 3 moderately to very strongly confused, each scale about two to four times as long as wide; Minnesota and Massachusetts to Kansas and North Carolina; many hosts; $1.6-1.9 \mathrm{~mm}$

- Declivital interstriae 3 and occasionally others uniseriately granulate; declivital scales in definite rows, except supplemental scales at suture, each scale two to six times as long as wide

11(10). Declivital scales four to six times as long as wide; setae on epistoma, frons and
scape less abundant, finer; body 3.1-3.2 times as long as wide; South Carolina
and Florida to E Texas; 1.5-1.7 mm .......................................... 9. nanula (LeConte)

- Declivital scales two to three times as long as wide; setae on epistoma, frons, and scape more abundant, longer; body 2.9-3.0 times as long as wide; S Texas to Veracruz; 1.7-1.9 mm

10. opacithorax Schedl

12(1). Strial punctures on disc fine to moderately large, distinctly, concavely impressed; interstriae up to one and one-half times as wide as striae; color usually light to dark brown13

- Strial punctures minute, feebly if at all impressed, their interiors flat; interstriae two to four times as wide as striae; color entirely or mostly black

13(12). Strial punctures on dise coarse, rather deep, interstriae very slightly narrower than striae; interstrial punctures very small, diameters less than one-third those of strial punctures, regularly spaced, rather close; frons convex in both sexes, very finely sculptured, reticulate, vestiture confined to lateral areas near eyes, very short; Oaxaca to Honduras; various lianas; $1.2-1.5 \mathrm{~mm}$ 12. striata Wood

- Strial punctures on disc smaller, interstriae distinctly wider than striae; diameters of interstrial punctures about half those of strial punctures; frons of both sexes flattened or impressed (except serjaniae); frontal pubescence more abundant, usually longer

14(13). Frons convex in both sexes, a feebly transverse impression just above male epistoma, frontal vestiture rather sparse, very short; vestiture on pronotal disc of slender, almost hairlike setae, a few scales near base; Honduras; Seriania; $1.2-1.3 \mathrm{~mm}$
13. serjaniae Wood

- Frons flattened or impressed in both sexes, vestiture longer, more abundant ........... 15

15(14). Male frons with a narrow, rather deep, transverse impression, impression on median third extending almost half distance to upper level of eyes; female frons broadly flattened to upper level of eyes, glabrous, impunctate, almost smooth; elytral disc subglabrous, scales widely spaced on declivity; Jalisco; Phoradendron; $1.5-1.7 \mathrm{~mm}$

- Male frons less strongly, more broadly impressed, female frons less extensively flattened; interstrial scales more closely, more regularly spaced from base to apex

16(15). Declivital interstriae uniseriately granulate; interstrial scales on declivity smaller, about half as long as distance between rows; pronotal scales on disc slender, about four times as long as wide; Nayarit; Seriania, $1.4-1.5 \mathrm{~mm}$ 15. similis Wood

- Declivital interstriae punctured, not at all granulate; interstrial scales on declivity larger, each about three-fourths as long as distance between rows; scales on pronotal disc more abundant, each about twice as long as wide; Veracruz; Serjania; 1.3-1.4 mm

16. vescula Wood

17(12). Strial setae on disc and declivity scalelike, similar in shape to interstrial scales but only half as large; female frons concavely impressed on small area just above epistoma; female scape without tuft of long hair; Puebla to Oaxaca; Serjania; 1.3-1.5 mm

- Strial setae hairlike if present; female frons flattened or convex; female scapebearing a small tuft of long hair

18(17). Frons convex in both sexes, impunctate and glabrous except near eyes; eyes coarsely faceted, separated above by less than one and one-half times width of an eye; Honduras and Colombia; $1.3-1.5 \mathrm{~mm}$
18. nigra Wood

- Frons flattened at least on limited area, pubescence more generally distributed, longer; eyes widely separated, finely faceted 19
19(18). Elytral apex moderately divaricate, emargination joining costal margin at a point in line with granules on interstriae 1; pronotal disc dull, deeply reticulate, granules fine; male frons convex, narrowly flattened in female, sparsely pubescent in both; Guatemala; shrub; $1.5-1.8 \mathrm{~mm}$ 19. nigrella Wood
- Elytral apex deeply, broadly divaricate, emargination joining costal margin at a point in line with granules on interstriae 2; pronotal disc subshining, shallowly reticulate, granules rather coarse; male frons less strongly convex, flat in female, more conspicuously pubescent in both; Veracruz; Seriania; 1.5-1.6 mm ..

20. divaricata Wood

## 1. Micracisella adnata Wood

Micracisella adnata Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 55(3):24 (Holotype, female; 14 km E Huatusco, Veracruz, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from the allied knulli (Blackman) by the presence of six teeth on the anterior margin of the pronotum, by the finely tuberculate, almost unelevated declivital interstriae 3, by the wider interstrial scales, and by the median impression on the female frous.

Female.- Length $1.9-2.0 \mathrm{~mm}, 2.8$ times as long as wide; color very dark reddish brown.

Frons convex, with a narrow, subtriangular, median impression from near upper level of eyes to level of antennal insertion; surface reticulate-granulate, apparently with a few larger granules; vestiture of moderately abundant, coarse, moderately short setae. Eye slightly more than twice as long as wide; antenna as in knulli.

Pronotum 1.1 times as long as wide; as in knulli except anterior margin armed by six teeth, and posterior area rugulose-reticulate, punctures fine, shallow, obscurely subtuberculate. Vestiture abraded in type series.

Elytra 1.8 times as long as wide, 1.6 times as long as pronotum; outline as in knulli; striae not impressed, punctures fine, shallow; interstriae twice as wide as striae, subrugosely marked by irregular lines, punctures uniseriate, very fine, shallow, obscure. Declivity steep, convex, apex protruding, minutely divaricate, mucro absent; surface on lower two-thirds rugose-reticulate; striae obscure but visible; interstriae 1 obscurely, very minutely, uniseriately granulate, 2 with a few
granules on upper fourth, 3 with larger granules to junction with 9,7 and 9 with granules similar to 3. Vestiture abraded on disc; on declivity consisting of rows of minute strial hair and rows of suberect, interstrial scales; each scale with a slight arch or curl toward posterior, two to four times as long as wide; almost as long as distance between rows, slightly closer within a row, scales absent on lower half of interstriae 2.

Male.-Similar to female except (head concealed) strial punctures slightly deeper; declivital interstriae 1 and 3 feebly elevated, 9 distinctly elevated; interstrial scales averaging slightly more slender.

Distribution.- Veracruz.
MEXICO: Veracruz: 14 km E Huatusco, 7-VII-67, 270 m, No. 173. Quercus, S. L. Wood.

Notes.- The above treatment was based on the type series of 3 specimens.

## 2. Micracisella subnitida Blackman Fig. 147

Micracisella subnitida Blackman, 1943, Proc. U.S. Nat. Mus. 93:350 (Holotype, male; Santa Rita Mits., Arizona; U.S. Nat. Alus., 56403)
Diagnosis.- This species is distinguished from knulli (Blackman) by the smaller size, by the slightly impressed frons just above the epistoma, by the less conspicuous frontal vestiture, by the shorter, more slender vestiture, and by declivital interstriae 3, which is not elevated.

Male.- Length $1.7 \mathrm{~mm}, 3.0$ times as long as wide; color dark brown, pronotum slightly lighter.

Frons convex above, distinctly, transversely impressed on lower third; surface

Fig. 147. Micracini spp., heads antennae, protibiae: 1, Hylocurus biconcatus; 2, Hylocurus flaglerensis; 3-4, Hylocurus hirtellus; 5-6, Micracisella knulli; 7-8, Mieracisella sulmitida; 9-10, Stenocleptus sulcatus. (After Blackman 1943:pl. 29.)
rugose-reticulate laterally and above, convex area with several conspicuous granules; vestiture sparse, rather inconspicuous except for a conspicuous epistomal brush. Eye large, coarsely faceted, anterior margin sinuate.

Pronotum 1.07 times as long as wide; essentially as in knulli except surface of posterior areas more nearly rugose, with several small, isolated granules behind summit. Vestiture of short, slender scales and hair on posterior half.

Elytra 1.8 times as long as wide, 1.7 times as long as pronotum; outline and disc essentially as in knulli except interstrial punctures on anterior half replaced by rounded granules, greatly reduced to almost obsolete on posterior half. Declivity about as in knulli except interstriae 3 indistinctly elevated, with its granules more isolated, not as coarse. Vestiture of minute strial hair and interstrial rows of erect scales, each scale smaller, more widely spaced, and more slender than in knulli; scales spaced within a row by about three times length of a scale, scales on declivity up to twice as long as on disc, of equal thickness, those on interstriae 1 and 3 of about equal length.

Distribution.- Arizona and New Mexico.
USA: Arizona: Oracle, 13-VII, Hublard and Schwarz; Santa Rita Mts., H. F. Wickham. New Mexico: Antelope Wells, 21-VIII-63, light trap, B. C. Camphell.

Notes.- The holotype and two males compared to it were used in preparing the above treatment.

## 3. Micracisella mimetica Wood

Micracisella mimetica Wood, I974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):15 (Holotype, male; 5 km N Suchixtepec on Highway 175. Oaxaca, Mexico; Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from knulli Blackman by the larger size, by the frontal granules, by the shorter, broader elytral scales, and by the smaller denticles on the elevated declivital interstriae 3 .

Male.- Length 2.3-2.4 mm, 2.9 times as long as wide; color dark reddish brown.

Frons moderately convex except rather abruptly, strongly, transversely impressed on lower fourth; surface rugose-reticulate in marginal areas, more finely, rather obscurely rugose-reticulate in central area; upper twothirds with about 30 small, high, isolated
granules, two near center much larger; vestiture of uniformly distributed, short, coarse setae of moderate abundance. Eye oval, shallowly emarginate; twice as long as wide. Antennal club 1.0 times as long as wide; suture 1 reaching middle of club.

Pronotum 1.1 times as long as wide; outline and asperities as in knulli; anterior margin armed by six teeth, lateral pair much smaller; posterior areas rugose-reticulate, dull, with small, low, shining granules of moderate abundance. Vestiture on disc of recumbent scales, each scale about four times as long as wide; a few bristles in asperate area.

Elytra 1.9 times as long as wide; outline as in knulli; disc as knulli except surface irregular, with numerous transverse lines or wrinkles. Declivity as in knulli except interstriae 1 and 9 slightly more strongly convex but with denticles on summit much smaller. Vestiture recumbent, of interstrial scales except declivital interstriae 2,4 , and 8 glabrous; scales evidently slightly confused on odd-numbered interstriae, uniseriate on even-numbered interstriae; each scale two to three times as long as wide.

Female.- Similar to male in all respects; distinguished externally only by terminal terga of abdomen.

Distribution.- Oaxaca.
MEXICO; Oaxaca: 5 km N Suchixtepec on Highway 175, 4-VI-71, 9500 ft , mistletoe on oak. D. E. Bright.

Notes.- The above treatment was based on the type series of five specimens.

4.-Micracisella knulli (Blackman)<br>Fig. 147

Micracis knulli Blackman, 1943, Proc. U.S. Nat. Mus. 93(3165):34s (Holotype, female; Huachuca Mts., Arizona; U.S. Nat. Mus., 56402)
Diagnosis.- This is the only species in the genus with declivital interstriae 3 distinctly elevated and tuberculate; other distinguishing characters were mentioned in the above key.

Female.- Length 2.0-2.5 mm, 3.2 times as long as wide; color dark brown.

Frons rather strongly, transversely impressed on middle third, convex above, epistomal area elevated; surface reticulate-granulate; lateral areas with abundant, coarse, subplumose setae of moderate length,
glabrous on median fourth. Eye slightly more than twice as long as wide. Antennal club with sutures 1 and 2 strongly arcuate, 1 reaching middle of club.

Pronotum 1.2 times as long as wide; widest on basal half, sides feebly arcuate, almost parallel on more than basal half, rather narrowly rounded in front; anterior margin armed by four teeth (rarely more); summit slightly in front of middle, low; anterior area rather coarsely asperate; posterior area shining, smooth, with fine, isolated, moderately abundant, granulate punctures. Vestiture of moderately abundant, mixed coarse and fine, moderately long setae.

Elytra 2.0 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal three-fourths, narrowly submucronate behind; striae not impressed, punctures rather fine, moderately deep; interstriae almost smooth, one and one-half times as wide as striae, punctures fine, uniseriate, indistinctly granulate. Declivity steep, convex, apex acuminate, not divaricate; strial punctures smaller, deep; interstriae 1 feebly elevated, 2 flat, 3 moderately elevated, 7 and 9 not elevated, 1,3 , and 9 each with a row of moderately coarse tubercles. Vestiture of rows of minute, fine, strial hair, and rows of interstrial scales; each scale on disc about six times as long as wide, slightly longer than distance between rows or between scales within a row, on declivity two to four times longer than on dise and usually pointed.

Male.-Similar to female except transverse impression on frons absent, frontal pubescence more generally distributed but sparse in median area.

Distribution.-S Arizona to Michoacán and Hidalgo.

USA: Arizona: Ash Canyon, 7-VI-69, 1800 m, No. 84 , Miller Canyon, 22-VIl-58, 7-VI-69, 1800 m , No. 85, all from Huachuca Mits. in Quercus, S. L. Wood; Miller Canyon, I-VII-07, H. A. Kaeber; Santa Rita Mits., 29-VII-68, Salix, D. E. Bright. MEXICO: Michoacán: 9 km E Volcán Parícutin, 19-VI-65, 2500 m , No. 87, Quercus, S. L. Wood. Hidalgo: 17 km NE Jacala, 22-VI-53, 1700 m, Quercus, S. L. Wood.

Host.- Quercus spp., Salix sp.
Notes.- The above treatment was based on my 2 topotypic homotypes and on 129 other specimens.

## 5. Micracisella ocellata Wood

Micracisella ocellata Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):16 (Holotype, male; 5 km N Suchixtepec on Highway 175, Oaxaca. Mexico; Canadian Nat. Coll.)
Diagnosis. - This species is distinguished from nitidula Wood by the very deeply impressed declivital striae and by the moderately large punctures on the discal striae, each of which has a small, elevated, central point giving the appearance of an eye.

Male.- Length 1.9-2.3 mm, 3.5 times as long as wide; color dark reddish brown, pronotum usually darker.

Frons broadly convex, a slight, transverse impression immediately above epistoma; surface finely rugose-reticulate, a few fine punctures in lateral areas, a few small granules in median area of upper half; vestiture of very short, stout subplumose setae laterally and on upper half, a few longer setae along epistoma. Eye feebly emarginate; twice as long as wide. Antennal club as in allied species.

Pronotum 1.18 times as long as wide; essentially as nitidula except scales on disc distinctly wider.

Elytra 2.4 times as long as wide; outline about as in nitidula; striae not impressed, punctures large, distinctly impressed, each with a small, central, elevated granule giving appearance of an eye; interstriae as wide as striae, shining, almost smooth, punctures fine, uniseriate, rather close. Declivity rather steep, convex, with apex slightly produced; striae deeply impressed, punctures small, obscure; interstriae 1,2 , and 3 equally convex, almost half as high as wide, each bearing a row of low, rounded nodules on its lateral half, granules more obscure and smaller on 3; surface on lower half somewhat rugose-reticulate. Vestiture of rows of fine, short, strial hair, and interstrial rows of recumbent scales; each scale on disc eight or more times as long as wide, about four times as long as wide on declivity.

Female.- Similar in all respects to male; presumably those specimens with a few more setae on scape are females.

Distribution.- Oaxaca.
MEXICO: Oaxaca: 20.5 km N Oaxaca, 31-V-71, 9000 ft , Arbutus, D. E. Bright; 24 and 59 km S Valle Nacional, $24-\mathrm{V}-71,4000$ and 8500 ft , Arbutus, D. E. Bright; 5 km N Suchixtepec on Highway 175, 4-VI-7I, 9500 ft , Arbutus, D. E. Bright.

Host.- Arbutus sp.
Notes.- The above treatment was based on the type series of 57 specimens.

## 6. Micracisella nitidula Wood

Micracisella nitidula Wood, 1969, Brigham Young Univ. Sci. Buill., Biol. Ser. 10(2):37 (Holotype, female; 10 km NE Teziutlán, Puebla, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from the closely allied scitula Wood by characters summarized in the above key.

Female.- Length $1.7-2.2 \mathrm{~mm}, 3.1$ times as long as wide; color black.

Frons convex, less strongly on lower half, epistomal margin weakly elevated, surface very finely reticulate-granulate, reduced to minute points on small median area near epistoma; vestiture consisting of rather sparse, conspicuous, subplumose setae of moderate length to vertex. Scape twice as long as pedicel, bearing a small tuft of hair.

Pronotum 1.1 times as long as wide; widest just behind middle, sides rather strongly arcuate, weakly constricted on anterior third, rather narrowly rounded in front: anterior margin armed by six small teeth of equal size: summit near middle, rather broad; posterior area minutely reticulate-granulate, with a few minute, almost flat, granules toward summit; vestiture rather stout, moderately abundant, rather long.

Elytra 2.0 times as long as wide, 2.0 times as long as pronotum; sides almost straight and parallel on basal three-fourths, narrowly acuminate behind; striae not impressed, punctures small, shallow; interstriae twice as wide as striae, somewhat irregular, punctures very fine, uniseriate. Declivity convex, rather steep; strial punctures slightly deeper than on disc; interstrial punctures replaced by fine granules; apex subacuminate, mucro not developed, not at all divaricate. Vestiture consisting of very fine, moderately long strial hair and rows of erect interstrial scales, slightly longer on declivity; each scale on declivity slightly longer than distance between rows, similarly spaced within each row, each about six times as long as wide.

Male. - Similar to female except frons slightly more convex; scape not expanded, sparsely pubescent; strial punctures on declivity more distinct, lower ones minutely granulate.

Distribution.- Michoacán and Puebla to Chiapas.

MEXICO: Chiapas: 40 km SE Teopisca, 18-V-69, Arbutus, D. E. Bright; 11 km E San Cristóbal, 26-V-69, Arbutus, D. E. Bright. Michoacán: 26 km E Morelia, 14-V1-65, Arbutus, S. L. Wood. Oaxaca: 116 km S Oaxaca on Highway 113, 11-V-71, 2300 m , Arbutus, D. E. Bright; 5 km N Suchixtepec, $4-\mathrm{V1}-71,3100 \mathrm{~m}$, Arbutus, D. E. Bright. Puebla: $25 \mathrm{~km} \mathbb{W}$ Texmelucan, 13-VI-67. 2900 m . No. 28, Arbutus, S. L. Wood; 10 km NE Teziutlán, 2-V11-67, 1600 m , No. 142, Rubus, S. L. Wood.

Hosts.- Rubus sp., Arbutus sp.
Notes. - The above treatment was based on the holotype and 57 other specimens.

## 7. Micracisella scitula Wood

Micracisella scitula Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):37 (Holotype, male; 14 km E Huatusco, Veracruz, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from the allied nitidula Wood by characters summarized in the above key.

Male.- Length $1.6 \mathrm{~mm}, 3.0$ times as long as wide; color reddish brown.

Frons rather strongly convex, with a narrow, transverse impression just above epistomal margin; surface rather coarsely reticulate except almost smooth on small median area on lower half, a few very small granules scattered on upper half; vestiture sparse, very short in convex area, longer below.

Pronotum 1.2 times as long as wide; widest near middle, sides very feebly arcuate, almost parallel on more than basal half, rather narrowly rounded in front; anterior margin armed by four small teeth, median pair slightly larger; summit broad, near middle; posterior area coarsely reticulate, a few shining points evidently represent obsolete punctures; vestiture reduced to a few very stout bristles in marginal areas.

Elytra 1.8 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on slightly more than basal twothirds, rather broadly rounded behind except subacuminate at suture; striae not impressed, punctures small, distinct, anterior margins of some of them very feebly elevated; interstriae shining, subrugulose, punctures twothirds as large as those of striae, shallow, some obscure. Declivity convex, rather steep; strial punctures somewhat obscure; interstrial punctures on upper half replaced by rounded
granules; subreticulate toward suture near apex. Vestiture largely abraded on disc of type, evidently shorter than on declivity; on declivity consisting of rows of erect, interstrial scales, each scale almost as long as distance between rows, more widely spaced within each row except on 1 , broad, averaging about twice as long as wide. Apex acuminate, mucro short; not at all divaricate.

Distribution.- Veracruz.
MEXICO: Veracruz: 14 km E Huatusco, 7 -Vil-67, 1300 m , No. I73. Quercus, S. L. Wood.
Notes.- The above treatment was based on the unique male holotype.

## 8. Micracisella hondurensis Wood

Micracisella houdurensis Wood, 1956, Canadian Ent. 88:233 (Holotype, female; Olanchito, Yoro. Honduras; Wood Coll.)
Diagnosis. - Except as noted in the above key and in the description below, this species is very similar to nanula (LeConte).

Female.- Length $1.4-1.8 \mathrm{~mm}, 3.2$ times as long as wide; color dark brown, pronotum usually darker.

Head as in nanula except frontal impression less extensive, shallow, median carina very short, visible only immediately above epistomal margin. Pronotum as in nanula except granules in posterior area slightly larger and more generally distributed. Elytra as in nanula except strial punctures on dise very shallow, smaller, almost obsolete, on declivity strial punctures larger, very shallow; interstrial punctures smaller than those of striae, usually devoid of granules; interstrial scales slightly wider.

Male.-As male of namula except frons more strongly convex; granules on pronotal dise very slightly larger; elytral dise with surface smoother, strial punctures much larger, very shallow, distinct; dechivital surface smoother, punctures larger, deeper, interstrial scales wider, each about three times as long as wide.

Distribution.- Chiapas to Honduras.
MEXICO: Chiapas: El Rincón, 13-V-69, M. Camphell; 8 km S San Carlos, 6 -III- 53 , R. C. Bechtel. E. I. Schlinger. HONDURAS: Olanchito, Yoro, 19-V-, 2I-VI, 7, 30-VII-49, at light, E. C. Becker; Zamorano, Morazán, I8-IV-64, 700 m , No. 511 , unidentified shrub, S. L. Wood.

Notes.- The above treatment was based on the type series of 21 specimens and on 2 other specimens.

## 9. Micracisella nanula (LeConte)

Micracis nanula LeConte, I876, Proc. Amer. Philos. Soc. I5:368 (Holotype, female; Hanlover, Florida; Mus. Comp. Zool., I022)
Diagnosis.- This species is very closely related to hondurensis Wood and to opacicollis (LeConte). Refer to the key and to the treatment of those species for distinguishing characters.

Female.- Length $1.5-1.7 \mathrm{~mm}, 3.2$ times as long as wide; color very dark brown to almost black, elytra usually lighter.

Frons narrowly, subconcavely impressed on lower half, convex above; surface finely reticulate-granulate except almost smooth on median third of lower half, a fine, median carina from epistoma to deepest point in concavity; vestiture of short, stout setae to upper level of eyes. Eye very large, coarsely faceted, separated above by 1.1 times width of an eye, separated below by twice diameter of a facet. Antennal scape short, bearing a sparse tuft of long hair; club as described for genus.

Pronotum 1.15 times as long as wide; sides almost straight and parallel on basal half, rather narrowly rounded in front; anterior margin armed by four teeth (rarely up to six); summit slightly in front of middle, low; anterior area rather finely asperate; posterior area finely reticulate-granulate, dull, with small, isolated, shining granules to base. Vestiture of mixed fine and stout, short, moderately abundant setae.

Elytra 2.0 times as long as wide, 1.8 times as long as pronotum; sides straight and parallel on basal three-fourths, obtusely submucronate behind; striae not impressed, punctures small, moderately deep, spaced by more than diameter of a puncture; interstriae shining, somewhat irregular, more than twice as wide as striae, punctures minute, shallow, obscure. Declivity steep, convex, apex submucronate; surface reticulate-granulate on lower half; strial punctures deeper, perhaps very slightly larger than on disc; interstrial punctures finely granulate. Vestiture of rows of very fine, short, recumbent, strial hair, and rows of erect, interstrial scales; each scale four to six times as long as wide, about as long as distance between scales between rows and within a row, uniseriate on all declivital interstriae.

Male.- Similar to female except frons convex to small flattened area immediately above epistoma, median carina very short, near epistoma; tuft of setae on scape smaller; interstrial granules on declivity smaller, often absent on interstriae 2; interstrial scales shorter, each about three to four times as long as wide.

Distribution.- South Carolina and Florida to Texas.
USA: Florida: Apalchola, Big Pine Key, Biscayne, Gainesville, Hanover, Homestead, Key Largo, Key Vaca, Key West, Marathon, Miami, Missouri Key, Snead, Sugar Loaf Key. Georgia: Savannah, St. Catherine Island. Louisiana: Baton Rouge, Covington. Mississippi: Corinth, Natchez, Trimcane Swanp. South Carolina: Charleston, Jacksonboro. Texas: Rockport.

Hosts.- Acras sapota, Conocarpus erecta, Dipholia salicifolia, Mimosa sp., Pithecellobium guadaloupense, Prosopis sp., Quercus sp., Rhizophora mangle, Vitis sp.

Notes.- The above treatment was based on the holotype and on 81 other specimens.

## 10. Micracisella opacithorax Schedl

Micracisclla opacithorax Schedl, I940, An. Esc. Nac. Cienc. Biol., Mexico 1:340 (Syntypes, female; Matamoros and Mante, Tamaulipas, and Cardel, Veracruz, Mexico; Schedl Coll.
Diagnosis.- This species is distinguished from nanula (LeConte) as indicated below.

Female.- Length $1.6-1.9 \mathrm{~mm}, 3.0$ times as long as wide; color very dark brown, elytra often lighter.

Frons as in nanula except median line usually more conspicuously impressed; setae on epistoma, frons, and scape conspicuously longer and more abundant. Elytral declivity with scales as in nanula except very slightly longer, much wider, each about two to three times as long as wide.

Male.-Similar to female except sexual differences as in nanula.

Distribution. - S Texas to Veracruz.
USA: Texas: Brownsville, 26-III-5I, Prosopis, S. L. Wood; Kingsville. Cornell Univ. Lot 912, C. T. Reid; San Diego, 24-V-95, mesquite. MEXICO: Tamaulipas: jiménez, I5-VI-53, Mimosa, S. L. Wood; Matamoros, 2I-VII-30, at light, S. Flores; Mante, 9-VIII-30, 26-X-30, A. Dampf, and 13-1II-44. Veracruz: Cardel, 3-VIII-32, at light, R. Ruiz Soto.

Hosts.- Mimosa and Prosopis.
Notes.- The above treatment was based on 3 syntypes and on 36 other specimens.

## 11. Micracisella opacicollis (LeConte) Figs. 148-149

Micracis opacicollis LeConte, I878, Proc. Amer. Philos. Soc. 17:625 (Holotype, female, Detroit, Michigan; Mus. Comp. Zool., 1297)
Micracis asperulus LeConte, 1878, Proc. Amer. Philos. Soc. 17:626 (Lectotype, female; Detroit, Michigan; Mus. Comp. Zool., 1298, present designation); Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Bull. 25:196. Synonymy
Diagnosis.- This species is distinguished from nanula (LeConte) by the absence of interstrial granules on the declivity, by the closer, confused, interstrial scales on the declivity, particularly on interstriae 3, and by the broader interstrial scales. Further investigation could reduce this form to no more than a geographical race of namula.

Female.- Length $1.6-1.9 \mathrm{~mm}, 3.2$ times as long as wide; color very dark brown to black.

Frons as in nanula except impressed area slightly stronger and more extensive, median carina very feebly indicated; lateral and upper areas more coarsely granulate.

Pronotum as in nanula except granules in posterior area smaller, reduced posteriorly, usually obsolete near base. Stout setae more nearly scalelike.

Elytra as in nanula except strial punctures very slightly larger; declivital reticulation greatly reduced; interstrial punctures on declivity as large as those of striae, feebly granulate only near apex and in extreme lateral areas, punctures on 1 and 3 confused; interstrial scales shorter and stouter, each two to three times as long as wide, usually more dense and confused on 1 and 3 .

Male.-Similar to female except frontal carina almost obsolete; declivital scales in uniseriate rows except a supplemental sutural row present, no indication of granules in apical portion of lateral areas.

Distribution.- Minnesota and Massachusetts to Kansas and North Carolina.

USA: District of Columbia: Washington. Kansas: "Kansas Knaus." Massachusetts: Framingham, Sherborn. Michigan: Detroit. Minnesota: Ramsey Co. Missouri: Scott Co., St. Louis. New Jersey: Camden, Gloucester Co., Westville. New York: Greenwood Lake, Ithaca. Westbury. North Carolina: Boardman, Tryon. Ohio: Oak Hill. Pennsylvania: Hummelstown, Mont Alto. Virginia: Afton. West Virginia: Monongalia.

Hosts.- Carya sp., Castanea dentata, Quercus alba, Q. falcata.

Notes.- The above treatment was based on the holotype of opacicollis, on the
syntypes of asperulus, and on 186 other specimens. The holotype of opacicollis and the syntypes of asperulus are females, not males as reported by LeConte. Because a type has not been selected from the 4 syntypes of asperulus, I here designate the first specimen now bearing the type label and number 1298 as the lectotype of asperulus LeConte.

## 12. Micracisella striata Wood

Micracisella striata Wood, 1956, Canadian Ent. 88:23I (Holotype, female; Olanchito, Yoro, Honduras; Wood Coll.)
Diagnosis.- This distinctive species has coarse, deep, strial punctures, with the interstriae narrower than the striae, and convex in both sexes.

Female.- Length $1.2-1.5 \mathrm{~mm}, 3.0$ times as long as wide; color yellowish brown.

Frons rather strongly convex, a slight, narrow impression just above epistoma; surface reticulate-granulate, finely below, more coarsely above, except almost smooth near center; vestiture confined to a few short, stout setae near margins of eyes. Antennal scape ornamented by a small tuft of hair; suture 1 not attaining middle of club.

Pronotum 1.1 times as long as wide; about as in nanula except anterior margin armed by two teeth, posterior area minutely rugulose, with a few rounded granules extending to base. Vestiture of a few small, stout setae.

Elytra 1.8 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal three-fourths, acuminate behind, costal margins notched just before apex; striae not impressed, punctures coarse, deep; interstriae shining, irregular, slightly narrower than striae, punctures fine, uniseriate, their anterior margins slightly elevated. Declivity steep, convex, apex extended; strial punctures reduced, very small toward apex; interstrial punctures slightly larger than on disc. Vestiture of rows of minute, fine, strial hair, and rows of erect, interstrial scales; each scale about three times as long as wide, slightly shorter than distance between rows or between scales within a row.

Male.-Similar to female except tuft of hair on scape smaller; interstrial punctures on posterior half of disc more nearly granulate.

Distribution.- Oaxaca to Honduras.
MEXICO: Oaxaca: II km N Matías Romero, 24-V1$67,150 \mathrm{~m}$, No. 95 , liana, S. L. Wood; 29 km N Matías

Romero, 29-VI-67, 150 m , No. 121, Seriania, S. L. Wood. HONDURAS: Olanchito, 19-V, 21-VI, 22-VII, 8-LX-49, at light, E. C. Becker; La Ceiba, I8-V, 17,28-VI-49, at light, E. C. Becker.

Hosts.- Serjania sp., and other small vines (lianas).

Notes.- The above treatment was based on the type series of 19 specimens and on 36 other specimens.

## 13. Micracisella serianiae Wood

Micracisella serjamiae Wood, 197I, Brigham Young Univ. Sci. Bull., Biol. Ser. I5(3):25 (Holotype, female; Zamorano, Morazán, Honduras; Wood Coll.)
Diagnosis.- This species is distinguished from striata Wood by the much smaller strial punctures, by the less nearly granulate discal interstriae, by the distinctly, uniseriately granulate declivital interstriae, by the absence of a preapical emargination on the costal margin, and by a distinct sutural emargination.

Female.- Length 1.2-1.3 mm, 3.0 times as long as wide; color very dark reddish brown, pronotum lighter.

Frons, antenna, and pronotum as in striata, except segment 1 of antennal club distinctly shorter.

Elytra 1.8 times as long as wide, 1.7 times as long as pronotum; outline as in striata except apex wider and suturally emarginate; striae not impressed, punctures moderately small; interstriae shining, somewhat irregular, one and one-half times as wide as striae, punctures fine, uniseriate, not at all granulate. Declivity steep, convex, produced apically; strial punctures deeper than on disc; interstrial punctures granulate. Vestiture as in striata except interstrial scales very slightly larger; each scale about two to three times as long as wide.

Male.-Similar to female except tuft of hair on scape much smaller; discal interstriae evidently less irregular.

Distribution.- Honduras.
hONDURAS: Zamorano, Morazán, IS-IV-64, 700 m , No. 547, Serjania racemosa, S. L. Wood.

Notes.- The above treatment was based on the type series of 85 specimens.

## 14. Micracisella monadis Wood

[^10]Diagnosis.- This species is distinguished from the allied vescula Wood and similis Wood by characters summarized in the above key.

Female.- Length $1.5-1.7 \mathrm{~mm}, 2.9$ times as long as wide; color dark brown.

Frons planoconvex from epistoma to well above eyes, epistomal margin slightly elevated toward center; surface very minutely, longitudinally etched, approaching reticulation laterally; glabrous. Scape more than three times as long as pedicel, broad, bearing a large tuft of hair.

Pronotum 1.1 times as long as wide; widest at middle, sides weakly arcuate on posterior two-thirds, weakly constricted on anterior third before rather narrowly rounded anterior margin; anterior margin armed by two basally contiguous, small teeth; summit at middle, broad; posterior areas coarsely reticulate, with a few minute granules near and behind summit; a few scales on marginal areas.

Elytra 1.7 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on more than basal two-thirds, narrowly rounded behind; striae not impressed, punctures very small, distinct; interstriae marked by lines, shining, three times as wide as striae, punctures fine, obscure. Declivity convex, rather steep; strial punctures larger, deeper, very obscure; interstrial punctures replaced by small rounded granules. Apex of elytra subacuminate. Vestiture consisting of very short, fine, strial hair and rows of longer, erect, interstrial scales; each scale slightly shorter than distance between rows, similarly spaced within rows, each scale about four times as long as wide, gradually, strongly narrowed toward their bases.

Male.- Similar to female except frons convex, a narrow, transverse impression just above epistoma, surface finely rugosereticulate, a few short, stout setae in lateral areas; tuft of hair on scape smaller; scape more slender; teeth on anterior margin of pronotum larger; declivital scales very slightly wider.

Distribution- Jalisco.
MEXICO: Jalisco: Volcán Colima, 23-VI-65, 2500 m , No. 105, mistletoe, S. L. Wood.

Host.-Struthanthus venetus.
Notes.- The above treatment was based on the type series of nine specimens.

## 15. Micracisella similis Wood

Micracisella similis Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):38 (Holotype, female; Volcán Ceboruco, Nayarit, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from the allied monadis Wood and vescula Wood by characters summarized in the above key.

Female.- Length $1.4-1.5 \mathrm{~mm}, 3.0$ times as long as wide; color black, summit of pronotum reddish brown.

Frons planoconvex, flattened toward center, gradually ascending to epistomal margin on lower fourth; surface minutely reticulategranulate, smoother medially toward epistoma; vestiture moderately long and abundant toward lateral areas, subplumose. Scape twice as long as pedicel, bearing a small tuft of long hair.

Pronotum 1.16 times as long as wide; widest at middle, sides on basal half straight, almost parallel, rather narrowly rounded in front; anterior margin armed by two moderately large, basally contiguous teeth; summit at middle, broad; posterior areas minutely reticulate-granulate, with a few, fine scattered granules; vestiture short, scalelike.

Elytra 1.9 times as long as wide, 1.7 times as long as pronotum; outline as in nitidula; striae not impressed, punctures small, shallow; interstriae marked by lines, shining, slightly less than twice as wide as striae, uniseriate punctures very fine. Declivity convex, rather steep; strial punctures somewhat reduced; interstrial punctures replaced by fine granules on upper half, almost obsolete below; general surface granulose toward sutural apex; apex acuminate, sutural apex shallowly emarginate. Vestiture consisting of minute, fine, strial hair and uniseriate rows of longer, erect, interstrial scales; each scale slightly shorter than distance between rows, similarly spaced within each row, each scale on declivity about three times as long as wide.

Male.- Similar to female except frons more nearly convex, frontal vestiture somewhat shorter; reduction of interstrial tubercles on lower half of declivity less pronounced.

Distribution.- Nayarit.
MEXICO: Nayarit: Volcán Ceboruco, 5-VII-65, 1200 m, No. I89, Seriania, S. L. Wood.

Notes. - The above treatment was based on the type series of nine specimens.

## 16. Micracisella vescula Wood

Micracisella vescula Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):38 (Holotype, female: 2 kim N Cerro Gordo, Veracruz, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from similis Wood by the coarser strial punctures, by the absence of interstrial granules on the declivity, and by the large, broader, interstrial scales.

Female.- Length $1.3-1.4 \mathrm{~mm}, 3.0$ times as long as wide; color dark brown, summit of pronotum reddish brown.

Frons as in similis but less strongly flattened. Scape twice as long as pedicel, bearing a tuft of long hair.

Pronotum 1.17 times as long as wide; outline as in similis; anterior margin armed by two moderately large subcontiguous teeth; posterior area minutely reticulate-granulate, with obscure, subgranulate punctures; vestiture of rather abundant, short scales, each twice as long as wide.

Elytra 1.8 times as long as wide, 1.6 times as long as pronotum; outline as in nitidula; striae not impressed, punctures rather fine, not always clearly defined; interstriae irregular, almost subrugose, as wide as striae, uniseriate punctures fine. Declivity convex, rather steep; strial punctures deeper than on disc, interstrial punctures equal in size to those of striae; apex acuminate, shallowly emarginate at sutural apex. Vestiture consisting of very fine, short, strial hair and interstrial rows of erect, uniseriate scales, each scale about as long as distance between rows, similarly spaced within each row, each about three times as long as wide; a supplemental row of smaller, sutural scales on declivity.

Male.- Similar to female except frons more strongly convex, frontal vestiture shorter; tuft of hair on scape much smaller; teeth on anterior margin of pronotum slightly larger.

Distribution.- Veracruz.
MEXICO: Veracruz: 2 km N Cerro Gordo, 6-VII-67, 1000 m, No. 166, Serjania. S. L. Wood.

Notes. - The above treatment was based on the holotype and allotype; no other specimens are known.

## 17. Micracisella squamatula Wood

Micracisella squamatula Wood, 1969. Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):38 (Holotype, female; 10 km S Huajuapan, Oaxaca, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from nigra Wood and the two preceding species by the much more widely spaced teeth on the anterior margin of the pronotum, by the scalelike, small, strial setae in addition to those of the interstriae, and by the more strongly divaricate elytra at the sutural apex.

Female.- Length $1.3-1.5 \mathrm{~mm}, 3.0$ times as long as wide; color black, summit of pronotum reddish brown, vestiture white.

Frons convex above, becoming flattened below, then ascending slightly to epistomal margin; surface reticulate-granulate above, becoming almost smooth in central area below except for a few fine points; vestiture rather abundant and long in large dorsolateral areas. Scape about twice as long and slightly wider than pedicel, bearing a small tuft of long hair.

Pronotum 1.1 times as long as wide; widest at middle, sides on posterior half almost straight and parallel on basal half, feebly constricted on anterior third, rather narrowly rounded in front; anterior margin armed by two moderately large, rather widely separated teeth; summit at middle, rather broad; posterior area finely reticulate-granulate, with a few minute granules; vestiture consisting of short, broad scales.

Elytra 1.8 times as long as wide, 1.7 times as long as pronotum; outline as in nitidula; striae not impressed, punctures small, somewhat indistinct; interstriae irregularly marked by fine points and lines, one and onehalf times as wide as striae, punctures fine, uniseriate. Declivity convex, rather steep; strial punctures evidently slightly deeper; interstrial punctures replaced by small rounded granules; sutural apex emarginate. Vestiture consisting of rows of small strial scales, each slightly longer than diameter of a strial puncture, about four times as long as wide, and rows of longer interstrial scales; each interstrial scale one and one-half times as long as strial scales and about equal in length to distance between rows of interstrial scales, each about three times as long as wide.

Male. - Similar to female except frons more strongly convex on upper two-thirds, smooth area much smaller and subreticulate; tuft of hair on scape reduced.

Distribution.- Puebla to Oaxaca.
MEXICO: Oaxaca: 10 km S Huajuapan, 16-V1-67, 2000 m , No. 45 , Serjania sp., S. L. Wood. Puebla: 6 km S Atlixco, 14-VI-67, 2300 m, No. 32, Seriania, S. L. Wood.

Host.-Serjania sp.
Notes.- The above treatment was based on the type series of 11 specimens and on 24 other specimens.

## 18. Micracisella nigra Wood

Micracisella nigra Wood. 1956, Canadian Ent. 88:232 (Holotype, female: La Ceiba, Atlántida, Honduras; Wood Coll.)
Diagnosis.- This species is distinguished from serianiae Wood by the black color, by the reduced granulation on the pronotal dise, by the very shallow strial punctures, and by the reticulate-granulate surface on the elytral declivity.

Female.- Length $1.3-1.5 \mathrm{~mm}, 2.8$ times as long as wide; color black.

Frons, antenna, and pronotum as in serjaniae, except teeth on anterior margin of pronotum distinctly separated, and pronotal disc almost devoid of granules and pubescence.

Elytra 1.7 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal three-fourths, obtusely produced behind, not emarginate at suture; striae not impressed, punctures small, very shallow; interstriae shining, irregular, twice as wide as striae, punctures mostly obsolete. Declivity steep, convex, produced toward apex; surface reticulate-granulate; strial punctures moderately deep, not clearly defined; interstriae uniseriately, regularly, rather coarsely granulate. Vestiture largely confined to declivity, consisting of rows of very fine strial hair and interstrial rows of erect scales; each scale three to four times as long as wide, each slightly shorter than distance between rows or between scales in a row.

Male.- Similar to female except tuft of setae on scape much reduced.

Distribution.- Honduras to Colombia.
HONDURAS: La Ceiba, Atlántida, 15, 29-V, 7, 28-VI49, at light, E. C. Becker; Olanchito, Yoro, 8-IX-49, at
light, E. C. Becker. COLOMBIA: Finca El Bosque near Caicedonia, Valle de Cauca, 10-V'Il-59, guamo verde, J. Restrepo.

Notes.- The above treatment was based on the type series of 12 specimens from Honduras and 5 other specimens from Colombia. The Colombia specimens are slightly larger, $1.5-1.6 \mathrm{~mm}$, and the strial punctures are slightly impressed on the disc but smaller and less strongly impressed on the declivity. In view of the very slight differences, without other supporting data, only one species was recognized here.

## 19. Micracisella nigrella Wood

Micracisella nigrella Wood. 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):37 (Holotype, female; Volcán de Agua, Esquintla, Guatemala; Wood Coll.)
Diagnosis.- This species is distinguished from nigra Wood by the coarser sculpture of strial punctures and declivital granules, by the larger, coarser, more abundant interstrial scales, and by the different arrangement of marginal teeth on the pronotum.

Female.- Length $1.5-1.8 \mathrm{~mm}, 3.0$ times as long as wide; color almost black, summit of pronotum reddish brown.

Frons convex on upper half, transversely impressed on lower half, an indistinct median impression toward center; vestiture sparse, of very short, fine, subplumose setae. Scape twice as long as pedicel, bearing a moderately large tuft of long hair.

Pronotum 1.14 times as long as wide; widest just behind middle, sides weakly arcuate on more than basal half, rather narrowly rounded in front, anterior margin armed by two rather large teeth; summit at middle, rather broad; posterior area minutely reti-culate-granulate, with moderately abundant, isolated, very fine granules; sestiture of rather short, broad scales.

Elytra 1.9 times as long as wide, 1.7 times as long as pronotum; outline as in nitidula; striae not impressed, punctures fine, distinct, shallow, interstriae with fine lines, twice as wide as striae, punctures very fine, half as large as those of striae. Declivity convex, rather steep; interstrial punctures about as large as those of striae; apex acuminate, sutural apex distinctly, shallowly emarginate. Vestiture consisting of rows of erect interstrial scales; each scale very slightly shorter
than distance between rows, similarly spaced within rows, each about two and one-half to three times as long as wide; a supplemental sutural row of smaller scales on declivity.

Male. - Similar to female except frons slightly more convex; scape without tuft of hair; elytral scales very slightly larger.

Distribution.-Guatemala.
guatemala: Volcán de Agua, Esquintla, 19-V-64. 1000 m , No. 603 , shrub, S. L. Wood.

Host.- A shrub, possibly Rhus sp.
Notes.- The above treatment was based on the type series of 83 specimens.

## 20. Micracisella divaricata Wood

Micracisclla ditaricata Wood. 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):39 (Holotype, female; 2 km N Cerro Gordo, Veracruz, Mexico; Wood Coll.)
Diagnosis.-- This species is distinguished from nigrella Wood and other representatives of the genus by the deep, broad emargination at the sutural apex of the elytra.

Female.- Length $1.5-1.6 \mathrm{~mm}, 2.8$ times as long as wide; color black, central area of pronotum reddish brown.

Frons planoconvex from epistoma to upper level of eyes; surface coarsely reticulate above and laterally becoming smooth toward center, punctures fine, moderately abundant; vestiture consisting of moderately long, stout, subplumose setae moderately abundant in lateral areas and above. Scape twice as long as pedicel, bearing a small tuft of long hair.

Pronotum 1.1 times as long as wide; widest on basal half, sides almost straight and parallel then arcuately rounded to constriction on anterior third, narrowly rounded in front; anterior margin armed by two rather large, basally contiguous teeth; summit rather indefinite, at middle; small asperities continue to just behind summit, isolated granules continue to base; surface of posterior area coarsely reticulate; vestiture of small, short scales.

Elytra 1.7 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on more than basal two-thirds, then narrowly rounded to blunt apex; striae not impressed, punctures very small; interstriae shining, marked by lines, twice as wide as striae, uniseriate punctures fine, somewhat obscure. Declivity convex, rather steep; strial
punctures largely obsolete; interstrial punctures replaced by rounded granules; apex divaricate, emargination as wide as width of antennal club and half as deep. Vestiture consisting of very minute, very fine strial hair and rows of longer, suberect, interstrial scales, each scale slightly shorter than distance between rows, similarly spaced within rows except closer on 1 , each scale about four times as long as wide.

Male. - Similar to female except frons more strongly convex, setae more evenly distributed; elytral scales wider, about three times as long as wide.

Distribution.- Veracruz.
Mexico: Veracruz: 2 km N Cerro Cordo, 6-vili-67. 1000 m , No. I66, Serjania, S. L. Wood.
Notes.- The above treatment was based on the type series of three specimens.

## Genus HyLOCURUS Eichhoff

Hylocurus Eichhoff, 1872, Berliner Ent. Zeit. 15:133 (Type-species: Hylocurus elegans Eichhoff, monobasic)
Micracisoides Blackman, 1920, Mississippi Agric. Expt. Sta. Tech. Bull. 9:19 (Type-species: Micracis rudis LeConte, present designation); Blackman, 1922, New York St. Coll. For., Syracuse, Tech. Pub. 16:144. Synomymy
Diagnosis.- This genus is closely allied to Phloeocleptus Wood and to Micracis LeConte. From Phlococleptus it is distinguished by the bisinuate to very strongly procurved antennal sutures, by the presence of tubercles on the posterior face of the protibiae, and by the xylophagous habit. The antennae and prothoracic tibia distinguish it from Micracis.

Description.- Length 1.3-3.2 mm, 2.3-2.9 times as long as wide; color reddish brown to black.

Frons usually sexually dimorphic, excavated to convex, commonly ornamented by carinae, tubercles, or hair in either sex. Eye small, short, entire; finely granulate. Antennal scape rather short, slender, rarely ornamented by hair (females of four species); funicle 6 -segmented; club moderately large, two bisinuate to strongly procurved sutures clearly marked by setae. Pronotum about as long as wide, summit distinct, at middle; anterior area finely asperate, anterior margin usually rather strongly serrate in male, in female finely serrate or unarmed; posterior area weakly to strongly reticulate, with
isolated granules, rarely punctured. Scutellum large. Elytra striate, interstriae uniseriately punctured; declivity usually sexually dimorphic, simply to elaborately sculptured. Vestiture of hairlike and/or scalelike setae. Anterior tibiae rather slender, wider apically; distal margin oblique, armed by several teeth; outer margin sinuate, unarmed; posterior face armed by several denticles or rugae.

Distribution.- The United States to Argentina; two phloeophagous African species of doubtful relationship have also been assigned to this genus; 51 American species have been placed in Hylocurus.

Biology.- The species are xylophagous and they breed in unthrifty, injured, recently cut, or totally dead branches, limbs, and boles ranging from about 2 to 20 cm in diameter. The male extends the entrance tunnel well
into the xylem tissues, where an elongate nuptial chamber is formed. Normally he is joined by two females, each of which constructs two egg galleries as in Micracis. Larval mines tend to follow the grain of the wood. Young adults apparently may remain in the brood host long after they mature; in at least one case (incomptus), an apparent second generation was produced without emerging.

Notes.- Blackman (1920) described Micracisoides as a subgenus of Micracis and later (1922) considered it a synonym of Hylocurus. He (1922) implied, but did not clearly state, that rudis LeConte was the species on which his concept of the group was based. In view of the ambiguity, 1 here designate Micracis rudis LeConte as the type-species of Micracisoides Blackman.

## Key to the Species of Hylocurus

1. Male elytral interstriae each with a series of two or more granules or tubercles
at declivital base, none of them particularly more prominent than others, these
not formed into a circumdeclivital ring; female frons variable, often pubescent,
sometimes bearing an elevation, or deeply excavated ......................................... 2

- Male elytral interstriae each with one prominent tubercle at posterior end of disc, these forming a conspicuous circumdeclivital ring; supplemental tubercles may also occur on declivity; female frons shallowly concave to convex, almost always with conspicuous pubescence
2(1). Both sexes with frons very deeply excavated and variously ornamented by
minutely pilose or spongy areas, E United States ....................................................... 3
- Frons flattened or convex, devoid of spongy areas ........................................................ 6

3(2). Frontal cavity bearing spongy areas on lateral walls, median area not at all elevated or bearing unusual prominences 4

- Frontal concavity, at least in female, partly or completely divided by a median $\quad$ elevation, or median area bearing a pair of blunt horns ............................................ 5

4a(3). Frons moderately excavated, center of each half of excavation occupied by a small circular, convex, spongy area; female declivity with a small protuberance on interstriae 1 near middle (similar to but smaller than in harnedi); Louisiana, Mississippi; Carya (Pecan); 1.8-2.0 mm 1. binodatus Wood

- Frons more deeply excavated, spongy areas larger; declivity without protuberance on interstriae 1
$4 \mathrm{~b}(4 \mathrm{a})$. Subcircular spongy areas largely flat, lower area sometimes protruding conspicuously; concavity very large, conspicuously wider than long, its ventrolateral angles occupied by spongy areas; Michigan and Pennsylvania to Kentucky and Georgia; $1.9-2.1 \mathrm{~mm}$ 2. rudis (LeConte)
- Spongy areas almost as high as wide, protruding into cavity from lateral areas; frontal concavity about as long as wide, its ventrolateral angles free of spongy areas; Illinois and Maryland to Alabama; 1.8-2.0 mm

3. torosus Wood

5(3). Spongy areas on median half of concavity, formed as a pair of basally separate median horns in male, in female fused medially and borne on a median elevation, elevation not reaching lower (orad) margin of concavity; Mississippi; Carya; 1.7-2.0 mm
4. bicornus (Blackman)

- Frontal concavity completely divided by a median partition, spongy areas absent; Kentucky; 2.0 mm

5. biconcavus Blackman

6(2). Elytral declivity with one large tooth or blunt process on or derived from interstriae 1 , when process remote from suture striae 1 and 2 obsolete on lower two-thirds of declivity, other declivital granules small; eastern United States

- Declivital interstriae 1 either unarmed or, if armed, its denticles smaller than on one or more other interstriae; declivital striae 1 and 2 never radically displaced
7(6). Female declivity armed by a pair of pointed, hornlike processes, each about as high as wide, located immediately above middle of declivity, a shallow sulcus between their bases; male declivity armed at suture just below upper margin by a large, slender, fingerlike blunt spine, about three or four times as long as wide; Mississippi; Carya; 1.8-2.2 mm (see also l. binodatus Wood)

6. harnedi Blackman

- Both sexes with a blunt process immediately below middle of declivity, in line with interstriae 3, each bluntly pointed, wider than high, slightly larger and wider in male; Pennsylvania to North Carolina; Carya; 1.8-2.0 mm

8(6). Frons in both sexes with a conspicuous, transverse, carinate elevation; declivital interstriae weakly elevated, serrations limited to about one tubercle; striae 1 and 2 obsolete on lower half of declivity

- Transverse elevation rare on male frons, female frons flattened and strongly pubescent (an irregular elevation in effeminatus); declivital interstriae 9 acutely elevated and/or serrate; declivital striae clearly punctured to apex (confused in dilutus)
9(8). Transverse frontal elevation equal in length to half width of frons; interstrial granules on male disc small, about two or three rather low tubercles on interstriae 3; elytra not sexually dimorphic; Chiapas to Guatemala; decaying limb; $2.1-2.5 \mathrm{~mm}$

8. incomptus Wood

- Transverse frontal elevation little more than a compressed tubercle, its length equal to considerably less than one-fifth width of frons; interstrial nodules on posterior third of male dise moderate to very coarse, continuing down declivity on 3 and lateral interstriae, about 10 nodules of equal size on interstriae 3 ; female interstriae finely granulate near and on declivity
10(9). Larger; elytral nodules less developed, declivity with a coarse tubercle on interstriae 1, 3, and 9; Florida; 2.2-2.4 mm

9. flaglerensis Blackman

- Smaller; elytral nodules in male strongly developed, declivity without tubercles conspicuously larger than nodules; Jalisco and San Luis Potosí to Costa Rica; bamboo; 1.6-2.2 mm

10. nodulus Wood

11(8). Declivital interstriae 9 joins costal margin and continues to apex; male declivital interstriae near base each with several nodules; mature color reddish brown 12
Declivital interstriae 9 separated from costal margin by a rather wide groove;
granules or nodules at base of male declivity usually smaller and less numerous ..... 13

12(11). Larger; male declivital interstriae 1-8 near base with several nodules extending to posterior area of disc; discal interstriae with transverse, irregular lines; strial punctures on declivity very small; declivital setae hairlike; Guatemala to Panama; Inga; 2.7-3.2 mm 11. simplex Blandford

- Smaller; declivital nodules fewer, larger, not extending to disc, obsolete or with only one nodule on interstriae 2 and 4; discal interstriae almost smooth; strial punctures on declivity larger; interstrial bristles on declivity broad; Veracruz; 1.8 mm

12. egenus Eichhoff

13(11). Strial punctures on lower half of declivity reduced in size and strongly confused; elytral tubercles small in both sexes; color reddish brown; Jalisco to Michoacán; 2.1-2.5 mm
13. dilutus Wood

- Striae 1 and 2 with punctures on lower half moderately large, impressed, in rows 14

14(13). Tubercles on declivital interstriae 3 continuing to junction with 9, tubercles normally also on 9 to this junction 15

- Tubercles on declivital interstriae 3 obsolete below junction with 5, tubercles
also absent on posterior part of 9 ; mature color black ......................................... 16

15(14). Larger; color reddish brown; interstrial nodules at base of male declivity very large, coarse tubercles continue to apices of interstriae 1 and 3 ; female frons with short, dense pile over large area; San Luis Potosí; Robinia; 2.3-2.6 mm .... 14. ruber Wood

- Smaller; very dark reddish brown to black; granules at base of declivity very small, granules on interstriae 1 small ; female frons pubescent on small area; setae rather long; Washington to Baja California; Salix, etc.; $1.4-1.8 \mathrm{~mm}$

## 15. hirtellus (LeConte)

16(14). Pronotal disc partly smooth and shining; elytral setae slender; female frons flattened and profusely pubescent over large area; Arizona to Michoacán; Quercus; 2.2-2.5 mm
17. femineus Wood

- Pronotal disc strongly reticulate, dull; interstrial setae at base of declivity stout in female, scalelike in male (except slender in both sexes of longipennis)
17(16). Interstriae 2 impressed on declivity, 2, 4, and 6 devoid of tubercles; tubercles on interstriae subacutely pointed; male frons with a transverse subcarinate elevation, more nearly tuberculate in female; Oaxaca; $1.7-2.1 \mathrm{~mm}$ (see also 16. longipennis Wood, Durango, 2.5 mm ) 18. effeminatus Wood
- Interstriae 2 on declivity not impressed, bearing fine tubercles to middle of declivity; interstrial nodules on posterior fourth of disc and upper fourth of declivity larger, broadly rounded, on interstriae 3-8; frons transversely impressed near epistoma, devoid of a transverse elevation
18(17). Male declivital interstriae 9 devoid of tubercles; tubercles on all declivital interstriae smaller, lower, and more widely spaced; discal interstriae smooth, with few transverse lines; pronotal disc shining, rather weakly rugosereticulate; Texas; 2.2 mm 19. schwarzi Blackman
- Male declivital interstriae 9 as coarsely tuberculate as 8; tubercles on all declivital interstriae coarse, almost as high as wide; discal interstriae with numerous strongly impressed irregular lines; pronotal disc strongly rugose-reticulate 19
19(18). Elytral declivity strongly reticulate, dull; discal striae near declivity strongly impressed, tubercles comparatively low; declivital interstriae 2 distinctly tuberculate to middle of declivity; pronotal dise with shallow punctures; "Mexico"; 2.4-2.7 mm

20. errans Blandford

- Elytral declivity smooth, shining; discal striae near declivity rather weakly impressed, tubercles coarse, higher than wide; declivital interstriae 2 unarmed except near base; pronotal disc almost devoid of punctures; Oaxaca; 2.1-2.7 mm .

21. rivalis Wood

20(1). Male declivital interstriae 9 strongly elevated, terminating abruptly or produced into a conspicuous spine without crossing broad, deep notch or groove at striae $9-10$, elytral apex longer, acute; female scape very sparsely if at all pubescent; female frontal pubescent area never divided along median line21

- Male declivital interstriae 9 acutely, strongly elevated and joining costal margin, a slight notch between costal margin and 9 in one species but striae 9-10 obsolete before notch; female scape bearing a conspicuous tuft of long hair (except elegans in which frontal pubescent area divided along median line); tropical species29

$21(20)$. Apices of blunt spines in circumdeclivital ring on male declivital interstriae 1
to 4 equal, or at least their apices forming a straight line (3 out of line in some
parkinsoniae) ..... 22

- Apices of spines in male circumdeclivital ring distinctly longer on interstriae 1,
3 , and 5 than on 2,4 , and 6 ; punctures intermixed with granules on pronotal
disc

22(21). Apices of interstrial spine 5 (and occasionally 3) in male circumdeclivital ring extending beyond (posterior to) 1 to 4 , posterior face of spines vertical, rarely projecting; female frons planoconvex, finely punctured, pubescence rather abundant but not dense; California to Texas; Cercidium, Condalia, etc.; 1.7-2.3 mm
22. parkinsoniae Blackman

- Apex of male circumdeclivital spine 5 in line with others

23(22). Male declivital face with at least one tubercle below circumdeclivital ring on interstriae $1,3,5,7$, and occasionally on others; female frons shallowly concave24

- Male declivital face with tubercles below circumdeclivital ring only on interstriae 1 and 3 ; female frons flat to convex

24(23). Denticles on declivital interstriae 3 extending lower, final pointed granule in line with 9 , slight elevation extending between apices of 3 and 9 , this elevation armed by granules in female; circumdeclivital tubercles in male well developed; strial punctures on posterior half of male dise very large, very deep; female frons distinctly convex, with an indistinct, central, transverse callus and moderately abundant vestiture; black; Guatemala; $2.6-2.9 \mathrm{~mm}$
23. cancellatus Blandford

- Declivital denticles on interstriae 3 ending higher on declivity, final pointed granule at junction of interstriae 3 and 7 usually on a weak elevation connecting these interstriae; male circumdeclivital tubercles less well developed, punctures on posterior half of disc much smaller, not as deep

25(24). Tubercles in male circumdeclivital ring poorly developed, two or more tubercles below this ring on interstriae 5 and 7, punctures on striae 1 and 2 almost as large as those in lateral areas; male frons flattened, female frons planoconcave, both pubescent on broad area three-fourths as wide as distance between eyes; Texas to Maryland and Florida; Celtis; 1.8-2.3 mm
24. langstoni (Blackman)

- Tubercles in male circumdeclivital ring well developed, projecting slightly, interstriae 5 and 7 never with more than one tubercle each below circumdeclivital ring, punctures on lower half of striae 1 and 2 small, very coarse on all striae near base of declivity; female frons shallowly concave and pubescent on median two-thirds; Tamaulipas to San Luis Potosí, 1.8-2.2 mm

25. medius Wood

26(23). Strial punctures on face of male declivity near apex almost as large as those near circumdeclivital ring; three tubercles on male declivital interstriae 3 smaller than those on 1; female frons broadly flattened and pubescent on median two-thirds or more; Puebla; Salix; 2.5-2.9 mm
26. microcornis Wood

- $\quad$ Punctures on face of male declivity on lower half of striae 1 and 2 about onethird as large as punctures near circumdeclivital ring; two tubercles on male declivital interstriae 3 larger than those on 1 ; female frons flattened and pubescent on median half; San Luis Potosí, 1.8-2.0 mm ............... 27. equidens Wood

27(21). Two or more spines on male circumdeclivital ring projecting more than twice basal width of spine; Honduras; Ficus: 2.2 mm
28. disparilis Wood

- $\quad$ None of spines on male circumdeclivital ring projecting more than basal width of spine 28

28(27). All spines in male circumdeclivital ring less well developed, long spines on upper half of declivity projecting no more than twice distance of short spines; large punctures on face of male declivity in definite rows, with distinguishable interstriae; Costa Rica; 1.7-2.5 mm
29. alternus Wood

- All spines in male circumdeclivital ring more strongly developed, longest spines projecting four or more times distance of short spines; large punctures on male declivital face much larger, deeper, confused; Nayarit to Oaxaca; Acacia, Inga; 1.5-2.1 mm

30. inaequalis Wood

29(20). Spines in circumdeclivital row of male blunt, rounded, symmetrical; female scape sparsely pubescent; female frons with pubescent area largely or completely divided into two parts; mature color almost black; Nayarit to Colombia; 1.3-1.8 mm
31. elegans Eichhoff

- Spines in circumdeclivital ring of male sharply pointed on lateral side of each spine; female scape bearing a tuft of long hair; female frontal pubescence uniformly distributed; body color reddish brown 30

30(29). Spines in male circumdeclivital ring projecting only slightly; male declivity more distinctly convex, strial rows easily discernible; female frons moderately concave, pubescence abundant; suture 1 on antennal club strongly procurved, extending beyond basal third; Nayarit, $1.9-2.2 \mathrm{~mm}$ (see also 35. punctatorugosus Schedl)-...................................................... 32. dissidens Wood

- Spines in male circumdeclivital ring projecting conspicuously, especially in lateral areas; male declivity more nearly flattened, strial rows seen with difficulty; female frons convex, pubescence rather sparse; suture 1 on antennal club weakly procurved; Costa Rica; $2.0-2.2 \mathrm{~mm}$ (see also 33. clarki Wood)

## 1. Hylocurus binodatus Wood

Hylocurus binodatus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):17 (Holotype, female; Nicholson, Mississippi; U.S. Nat. Mus.)
Diagnosis.- The frontal area of this species has a pair of raised spongy patches somewhat like the rudis group of species, but the elytral declivity is similar to harnedi Blackman.

Female.- Length 1.8-2.0 mm, 2.7 times as long as wide; color very dark brown, almost black.

Frons with a large, transversely reniform concavity from midway between epistoma and upper level of eyes to vertex, widest point at upper level of eyes, occupying threefourths of area between eyes: concavity rather abruptly impressed, moderately deep; central area of each half of concavity occupied by a protuberant, oval, spongy area, occupying about half of concave area; spongy areas rather narrowly separated from one another; general sculpture as in rudis; subglabrous.

Pronotum as in rudis except granules on dise smaller. Elytral dise as in rudis. Declivity as in rudis except tubercles distinctly larger; interstriae 1 with a moderately large protuberance at middle of declivity, slightly displaced from suture, almost as high as wide, similar to but smaller than female harnedi; interstriae 9 not more strongly elevated than in rudis. Vestiture as in rudis.

Distribution.- Louisiana to Mississippi.
USA: Louisiana: Algiers, 18-IN-45. No. 45-8751, pecan, Rau. Mississippi: Nicholson, 15-1-45, No. 45-2357, under hickory bark, W. H. Anderson.

Host.-Carya sp.
Notes. - The above treatment was based on the type series of three specimens.

## 2. Hylocurus rudis (LeConte) <br> Figs. 148-149

Micracis rudis LeConte, 1876, Proc. Amer. Philos. Soc. 15:369 (Holotype, female?; Detroit. Michigan; Mus. Comp. Zool., 1020)
Micracis biorbis Blackman, 1920, Mississippi Agric. Expt. Sta. Tech. Bull. 9:22 (Holotype, male; Syracuse, New York; U.S. Nat. Mus., 58217); Wood, 1972, Great Basin Nat. 32:196. Synonymy
Diagnosis.- This species is distinguished from torosus Wood by the larger frontal excavation, the spongy area ventrolateral in position, mostly flat, and distinctly larger.

Female.- Length 1.9-2.1 mm, 2.7 times as long as wide; color very dark brown.

Frons deeply, broadly excavated, margins of concavity abrupt except median area below; surface minutely etched to rugulose; ventrolateral areas of concavity occupied by large, subcircular, minutely pilose areas (appearing spongy) of somewhat variable size and position, lower halves of these areas moderately protruding, upper halves almost flat, these areas separated below by a distance about equal to one-fourth width of concavity (variable in series); glabrous except for minute pile. Antennal club with two bisinuate sutures.

Pronotum 1.1 times as long as wide; sides almost straight and parallel on slightly more than basal half, broadly rounded in front; serrations on anterior margin almost obsolete; summit poorly developed, in front of middle; asperities continue as granules to base; posterior area reticulate, with a few granules. Glabrous.

Elytra 1.6 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal three-fourths, a slight notch at end of elevated interstriae 9, subacutely acuminate and mucronate behind; striae weakly impressed, punctures rather coarse, deep; interstriae weakly convex, smooth, punctures fine, uniseriate, rather widely spaced. Declivity steep, convex, produced at apex; striae rather obscure, a slight impression below where 3 and 7 join; interstriae 9 rather strongly elevated, its apex declining gradually, all interstriae with several rounded granules; acuminate area tuberculate to its base. Vestiture of fine, moderately long hair, largely confined to declivity.

Male.-Similar to female except frontal excavation slightly smaller, not as deep, spongy areas flatter; declivital granules slightly larger except smaller on interstriae 1 and 2.

Distribution.- Michigan and Pennsylvania to Kansas and Georgia.

USA: District of Columbia: Washington. Georgia: Black's Mt., Clarksville. Kansas: Ottawa. Kentueky: Humble. Maryland: Jacksons, Plummers Island. Michigan: Detroit. New Jersey: Pequest. Ohio: Delaware Co., Franklin Co.. Westerville. Pennsylvania: Blain, Harrisburg. Hummelstown. Pittsburgh, University Park. Vir ginia: "Va."

Hosts.- Carya spp., Fagus grandifolia, Quercus velutina, Ulmus americana.

Biology. - Presumably as described for the genus.

Notes. - The above treatment was based on the holotypes of rudis and biorbis and on 43 other specimens.

Apparently there is a great deal of variation in the size of the spongy areas on the frons in this rare species.

## 3. Hylocurus torosus Wood <br> Figs. 148-150

Hylocurus torosus Wood, 1971, Brigham Young Univ: Sci. Bull., Biol. Ser. 15(3):2S (Holotype, female; Florence, South Carolina; Wood Coll.)

Diagnosis.- This species is distinguished from rudis (LeConte) by characters of the frontal excavation and its protuberances as noted below.

Female.- Length $2.0 \mathrm{~mm}, 2.7$ times as long as wide; color very dark brown.

Frons deeply excavated on median twothirds from just above epistomal margin to well above eyes, broadly oval in outline, its margins abrupt on all sides; surface etched as in rudis; lateral walls of concavity with a pair of large, protruding, subcircular areas, almost as high as wide, pile longer than in rudis.

Antenna, pronotum and elytra as in rudis.
Distribution.- Illinois and Maryland to Alabania and South Carolina.

Fig. 148. Micracini spp., antennae: 1, Hylocurus torosus, female; 2, Hylocurus rudis (=biorbis), female; 3, Hylocurus bicornus, female; 4, Hylocurns harnedi, female; 5, Hylocurus langstoni, female; 6-7, Micracis suturalis, female, 8, same, male; 9-10, Micracis swainei ( 9 is an abnormally slender club), female; 11, Micracisclla opacicollis, female. (After Blackman 1920:pl. I.)

USA: Alabama: Corona Mines, 18-[X-76, B. A. Hawkins. Illinois: Pine Hills Field Station, Union Co., 15-V67. Maryland: Plummers Island, Carya and Celtis, A. D. Hopkins. North Carolina: Tryon, Acer, Carya, Casanea dentata, S. F. Fiske. South Carolina: Florence, 12-V-61, in flight, V. M. Kirk.

Notes. - The above treatment was based on the holotype and on 10 other specimens.

## 4. Hylocurus bicornus (Blackman)

Figs. 148-149
Micracis bicornus Blackman, 1920, Mississippi Agric. Expt. Sta. Tech. Bull. 9:23 (Lectotype, female; Mendenhall, Mississippi; U.S. Nat. Mus., present designation.)
Diagnosis.-- This species is distinguished from rudis (LeConte) by the very different sculpture of the frons as noted below.

Female.-- Length $1.7-2.0 \mathrm{~mm}, 2.7$ times as long as wide; color very dark brown.

Frons excavated about as in rudis except bilobed spongy areas borne on a strongly elevated median partition; spongy area about one-fourth as wide as frontal concavity.

Pronotum as in rudis except posterior area less distinctly reticulate. Elytra as in rudis except striae indistinctly impressed, punctures smaller, not as deep; declivity more finely sculptured, more nearly shining.

Male.-Similar to female except frontal excavation not as deep, median partition absent, spongy areas borne on paired processes arising from median half of floor of concavity, basally, narrowly separated, each process higher than wide, its basal longitudinal axis about twice as great as its transverse axis.

Distribution.- Mississippi.
USA: Mississippi: Mendenhall, 26, 30-XII-I9, hickory, M. W. Blackman.

Host.- Carya sp.
Biology.- Apparently as described for the genus.

Notes.- The above treatment was based on the lectotype, on the lectoallotype, and on 20 other specimens. The female syntype in the U.S. National Museum, labeled as the holotype, is here designated as the lectotype of this species.

## 5. Hylocurus biconcavus Blackman Fig. 147

Hylocurus biconcacts Blackman, 1943, Proc. U.S. Nat. Mus. 93:344. (Holotype, female?; Kentucky; U.S. Nat. Mus., 56397)

Female.- Length $2.0 \mathrm{~mm}, 2.7$ times as long as wide; color almost black. As in bicornus (Blackman) except large, deep, transversely oval frontal excavation completely divided by a narrow median partition; slightly spongy texture limited to summit of this partition.

Distribution.-Kentucky. USA: Kentucky: "Ky."
Notes.- The above treatment was based on the holotype. Insufficient material is available to evaluate the status of this species.

## 6. Hylocurus harnedi (Blackman)

Figs. 148-149, 151

Micracis harnedi Blackman, 1920, Mississippi Agric. Expt. Sta. Tech. Bull. 9:24 (Lectotype, female; Mendenhall, Mississippi; U.S. Nat. Mlus., present designation)
Diagnosis.- This species and the allied spadix Blackman are remotely related to other known Hylocurus. In both species the elytral declivity is armed by only one pair of prominent, blunt elevations, these apparently derived from interstriae 1. In the harnedi male these processes are basally subcontiguous at the suture just below the base of the declivity, and in the female they are just above the middle of the declivity about in line with interstriae 2.

Female.- Length $1.8-2.2 \mathrm{~mm}, 2.8$ times as long as wide; color almost black.

Frons obscured in available specimens; evidently moderately convex and finely granulate, with sparse vestiture. Pronotum essentially as in bicornus.

Elytra 1.7 times as long as wide; sides almost straight and parallel on more than basal two-thirds, abruptly rounded, then strongly acuminate behind, with a pair of projecting declivital processes interrupting outline; striae feebly impressed toward declivity, punctures moderately coarse, deep; interstriae as wide as striae, weakly convex posteriorly, shining, with occasional transverse lines, punctures fine, often rather obscure, uniseriate, becoming finely granulate on posterior third. Declivity very steep, broadly convex; striae 1 and 2 apparently obsolete; a large, pointed elevation just above middle of declivity in line with interstriae 2, higher than wide; a shallow impression between
horns from base of declivity to base of acuminate elytral apex; interstriae lateral to horns bearing uniseriate, isolated, pointed granules; interstriae 9 rather strongly elevated, elevation terminated abruptly behind. Vestiture confined to declivital base, of sparse, stout, almost scalelike setae.

Male.-Similar to female except sutural interstriae bearing a rather slender, blunt, fingerlike process near base of declivity, interstriae 3 convex and uniseriately granulate to middle of declivity, not bearing a pair of horns at this position; declivital interstriae 9 more strongly elevated.

Fig. 149. Micracini spp., protibiae: 12, Hylocurus torosus, female; 13, Hylocurus rudis, female; 14, Hylocurus bicornus, female, 15, same, male; 16, Hylocurus harnedi, female; 17. Hylocurus langstoni, female; 18-19, Micracis suturalis, female; 20-21, Micracis swainci, female; 22, Micracisclla opacicollis, female. (After Blackman 1920:pl. II.)

Distribution.- Mississippi.
USA: Mississippi: Mendenhall, 30-XII-19, Carya, M. W. Blackman.

Biology.- Specimens were removed from hickory branches. The gallery systems apparently were as described for the genus.

Notes.- The above treatment was based on the lectotype, on the lectoallotype, and on three paratypes. The female syntype from Mendenhall, Mississippi, that was labeled "type" by Blackman is here designated as the lectotype of this species.

## 7. Hylocurus spadix Blackman

Hylocurus spadix Blackman, 1928, Bull. New York St. Coll. For., Syracuse Tech. Bull. 25:188 (Holotype, female; Tryon, North Carolina; U.S. Nat. Mus., 27131)

Diagnosis.- This species is distinguished from harnedi Blackman by the pair of declivital spines below the middle of the declivity, located in the same position in both sexes (in line with interstriae 3).

Male.- Length $1.8-2.0 \mathrm{~mm}, 2.8$ times as long as wide; color almost black.

Frons and pronotum as in harnedi.
Elytra 1.6 times as long as wide; outline as in hamedi; striae feebly impressed at base, more strongly toward declivity, punctures rather coarse, deep; interstriae almost as wide as striae, smooth with a few transverse lines, punctures uniseriate, fine, rather coarse, uniseriate granules at declivital base. Declivity very steep, rather broadly convex; a pair of large, blunt, almost mammiform elevations at or just below middle of declivity in line with interstriae 3 , almost as high as wide, basal width slightly greater than width of an interstriae; lateral areas with granules and interstriae 9 as in harnedi. Vestiture of sparse, stout setae at base of declivity.

Female.- Similar to male except declivital granules much smaller, interstriae 9 less strongly elevated; mammiform declivital elevations with smaller basal width but equal in height.

Distribution.- Pennsylvania to North Carolina.

USA: North Carolina: Tryon. Hopk. U.S. 3190B, hickory, W. F. Fiske. Pennsylvania: Linglestown, 2-VIII-13, hickory, A. D. Hopkins.

Host.- Carya.
Biology.- Presumably as in harnedi.

Notes.- The above treatment was based on the holotype, allotype, two paratypes, and on one other specimen.

## 8. Hylocurus incomptus Wood

Hylocurus incomptus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):44 (Holotype, male; Volcán de Agua, Esquintla, Guatemala; Wood Coll.)
Diagnosis.- This species is distinguished from nodulus Wood by characters summarized in the above key.

Male.- Length 2.1-2.5 mm, 2.6 times as long as wide; color black.

Frons moderately convex, epistomal margin slightly elevated; a conspicuous, transverse carina occupying median half at upper level of eyes; surface coarsely reticulate, sparse punctures minute; vestiture inconspicwous except on epistomal margin. Eye smaller than in related species.

Pronotum 1.2 times as long as wide; widest at base, sides almost straight, converging slightly anteriorly on posterior two-thirds, broadly rounded in front; anterior margin subserrate; sculpture as in femineus Wood, with tubercles behind summit finer, becoming obsolete at base; vestiture inconspicuous, hairlike.

Elytra 1.5 times as long as wide, 1.4 times as long as pronotum; sides straight and parallel on basal two-thirds, rather abruptly rounded behind, median fourth extending into a rather well-developed mucro; striae not impressed, punctures fine, shallow but distinct; interstriae about three times as wide as striae, marked by irregular lines, almost flat, punctures minute, widely separated, becoming finely granulate on posterior fourth. Declivity convex, very steep; strial punctures obscure; interstriae 3 weakly, 9 moderately elevated, 1 feebly raised and terminating apically in mucro; all interstriae with a row of tubercles on upper third, minute on 2 , rather coarse on 3 , and last tubercle on 9 , those on 3 extend to middle, on 1 two or three minute granules scattered on lower half. Vestiture hairlike, consisting of rows of short strial and slightly longer interstrial setae on declivity.

Female.- Similar to male except evidently very slightly more finely sculptured; declivital vestiture longer and more abundant.

Distribution.- Chiapas to Guatemala.
MEXICO: Chiapas: 13 km Ne San Cristóbal, I5-V-69, Quercus. D. E. Bright. GUATEMALA: Volcán de Agua, Esquintla, 19-V-64, 1090 m , No. 616, S. L. Wood.

Biology.- The original series was taken from an old, decaying, fallen limb, 20 cm in diameter, of an unidentified tree. The

Fig. 150. Micracini, dorsal aspect: 35, Hylocurus torosus; 36, Micracis swainei, female; 37, Micracis suturalis, female, 38, same, male. (After Blackman 1922, pl. VII.)
galleries were such that it appeared more than one generation had been completed within this one limb; there were no exit holes or indications that the mature beetles were making tunnels in the direction toward the surface of the limb.

Notes.- The above treatment was based on the type series of 69 specimens and on one other specimen.

## 9. Hylocurus flaglerensis Blackman Fig. 147

Hylocurus flaglerensis Blackman, 1943, Proc. U.S. Nat. Mus. 93:345 (Holotype, female; Flagler Co., Florida; U.S. Nat. Mus., 56400)
Diagnosis.- This species is somewhat intermediate between incomptus Wood and nodulus Wood, but it is distinguished by the larger size, by the larger upper declivital tubercles, and by other characters mentioned below.

Male.- Length 2.2-2.4 mm, 2.5 times as long as wide; color almost black.

Frons as in nodulus; pronotum as in incomptus except posterior area feebly reticulate, almost shining, granules narrower.

Elytral outline as in incomptus; striae not impressed, punctures rather coarse, deep; interstriae very slightly wider than striae, uniseriate punctures rather coarse, their anterior sides elevated to form fine nodules that become distinctly larger toward declivity, largest about half as high as wide. Declivity convex, moderately steep, apex acuminate; arrangement of tubercles basically as in incomptus, interstriae 1 armed by a moderately large tooth just below base of declivity, 3 bearing a rather coarse, blunt tooth near middle of declivity, two or more smaller tubercles may occur dorsad of this major one, one small tubercle at or near apex of 5 and 7 , tubercle at junction of 3 and 9 proportionately smaller than in incomptus. Vestiture of rather long, coarse hair of moderate length.

Distribution.- Florida.
USA: Florida: Marion Co., 31-I-30, fruit fly trap, R. B. Mathews.

Notes.- The above treatment was based on the holotype and paratype.
10. Hylocurus nodulus Wood

Fig. 152
Hylocurus nodulus Wood, 1956, Canadian Ent. 88:141
(Holotype, male; Pujal, San Luis Potosí, Mexico; Snow Ent. Mus., Univ. Kansas)

Diagnosis.- This species is in the robustus Schedl group of species, but it is very distinct. It is distinguished from North American forms by characters included in the above key.

Male.- Length $1.6-2.2 \mathrm{~mm}, 2.5$ times as long as wide; color almost black.
Frons convex, a moderately deep, rather narrow, transverse impression at level of antennal insertion; surface somewhat granulatepunctate, a conspicuous, rather coarse, transversely compressed median granule at upper level of eyes. Antennal club subcircular, with sutures 1 and 2 weakly procurved.

Pronotum 1.1 times as long as wide; sides very feebly arcuate, subparallel on basal half, rather narrowly rounded in front; anterior margin armed by two coarse, closely set teeth; posterior surface obscurely reticulate, with rather numerous isolated granules toward summit. Vestiture of sparse, coarse hair.

Elytra 1.4 times as long as wide, 1.3 times as long as pronotum; outline about as in rudis; striae not impressed, punctures small, distinct at base, becoming larger, malformed toward declivity; interstriae smooth, with distinct punctures on basal third, 1 and 2 with large, rounded nodules on middle third, higher and more acutely rounded behind on all interstriae. Declivity confined to posterior third; steep, convex, produced at apex; strial punctures very small, not always clearly formed; interstriae 1 elevated toward apex, 3 weakly, broadly raised on middle third, 1 and 2 unarmed, others with tubercles on upper two-thirds, lower one or two tubercles on 3 larger, 9 rather weakly elevated, not tuberculate. Vestiture largely confined to declivity; of coarse, blunt, moderately long interstrial bristles.

Female.- Similar to male except frontal impression not as deep; teeth on anterior margin of pronotum smaller; all nodules and granules on elytra rather small; vestiture of slender, pointed bristles.

Distribution.-Jalisco and San Luis Potosí to Costa Rica.

MEXICO: Jalisco: Guadalajara, 26-VII-42, bamboo (Nogales interception No. 55.381). San Luis Potosí: Pujal, 20-Vl-53, bamboo, S. L. Wood. HONDURAS: La Lima, Cortez, 5-V-64, 200 m , bamboo, S. L. Wood. COSTA R1CA: Santa Ana, San José, 1-VIII-63, No. 94, bamboo, S. L. Wood; San José, San José, 12-IX-63. No. 161, 22-X63. No. 239, Bambusa vulgaris, S. L. Wood.

Hosts.- Bamboo.
Biology.- Essentially as described for the genus.

Notes.- The above treatment was based on 15 paratypes and on 33 other specimens.

## 11. Hylocurus simplex Blandford <br> Fig. 152

Hylocurus simplex Blandford, 1898, Biol. Centr. Amer., Coleopt. 4(6):222 (Holotype, male; El Tumbador, San Marcos, Guatemala; British Mus. Nat. Hist.)
Diagnosis.- This species has several equal, uniseriate interstrial tubercles at the base of the declivity, and interstriae 9 joins the costal margin.

Male.- Length 2.7-3.2 mm, 2.7 times as long as wide; color reddish brown.

Frons rather strongly convex, abruptly, transversely impressed on lower third; surface brightly shining, smooth, with large, deep, close punctures uniformly distributed from impression to vertex; glabrous. Antennal club subcircular; two weakly procurved sutures.

Pronotum 1.1 times as long as wide; widest at base, sides almost straight, converging slightly on basal half, rather narrowly rounded in front; anterior margin irregularly serrate; posterior area subreticulate, with isolated granules extending to base. Glabrous.

Elytra 1.6 times as long as wide, 1.5 times as long as pronotum; outline about as in rudis; striae distinctly impressed, punctures moderately small, very close, deep; interstriae smooth, shining, a few transverse lines, punctures small, almost uniseriate; each interstriae with two coarse, rounded nodules at base of declivity except 3 and 5 with more. Declivity steep, convex, produced at apex; striae not impressed, punctures small, rather shallow; interstriae smooth, shining, 1 with a few small granules on lower half, 3 with four to eight rather large, rounded nodules on upper two-thirds, 5 and 7 each with five nodules at base, $2,4,6$, and 8 smooth except at extreme base, 9 subacutely, rather strongly elevated and joining costal margin; a few granules on or near apex. Glabrous except for a few hairlike setae near base of declivity.

Female.-Similar to male except frons flattened on median half, transverse impression absent, flattened area finely punctured,
with abundant, fine, hairlike setae of moderate length; anterior margin of pronotum unarmed; declivital interstrial tubercles slightly smaller, mostly pointed, larger and more abundant on 1, more abundant (10) on 3.

Distribution.- Guatemala to Panama.
guatemala: el Tumbador, San Marcos, g. C. Champion. PANAMA: Cerro Punta, 19-XII-63, No. 315. 11-I-64, No. 404, 1800 m , Inga, S. L. Wood.

Host.- Inga sp.
Biology.- As described for the genus. Specimens were taken from dying limbs and boles up to 15 cm in diameter.

Notes.- The above treatment was based on the holotype and on 15 other specimens. The holotype is a male, not a female as stated by Blandford.

## 12. Hylocurus egenus Blandford

Hylocurus egenus Blandford, I898. Biol. Centr. Amer., Coleopt. 4(6):222 (Holotype, male; Motzorongo, Veracruz, Mexico; British Mus. Nat. Hist.)
Diagnosis.- This species is distinguished from simplex Blandford by the smaller size, by the elimination of nodules on declivital interstriae 2 and their reduction to one on 4 , by the coarser declivital strial punctures, by the smoother discal interstriae, and by the scalelike interstrial setae on the declivity.

Male.- Length $1.8 \mathrm{~mm}, 2.6$ times as long as wide; color reddish brown.

Frons of type not clearly visible, evidently similar to simplex.

Pronotum 1.15 times as long as wide; as in simplex except basal areas more strongly reticulate, granules finer, less numerous.

Elytra 1.5 times as long as wide, 1.3 times as long as pronotum; outline as in simplex; striae weakly impressed, punctures rather coarse, deep; interstriae as wide as striae near declivity, twice as wide as striae near base, smooth, shining, punctures fine, uniseriate, rather sparse, with no transverse lines. Declivity steep convex; about as in simplex except strial punctures larger, deeper, interstriae 2 without nodules, 4 with one, those on 1 and 3 sharply pointed; nodules not extending to disc. Vestiture confined to declivity where nodules, punctures, or tubercles occur, consisting of erect, flattened interstrial bristles, each as long as distance between
rows, each about six to eight times as long as wide.
Distribution.- Veracruz.
MEXICO: Veracruz: Motzorongo, Flohr.
Notes. - The above treatment was based on the male holotype.

## 13. Hylocurus dilutus Wood

Hylocurus dilutus Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):29 (Holotype, male; Volcán Colima. Jalisco, Mexico; Wood Coll.)
Diagnosis.- This species is allied to simplex Blandford and ruber Wood, but it is distinguished by the smaller average size, by the smaller interstrial tubercles in both sexes, and by the small, confused strial punctures on the declivity.

Male.- Length 2.1-2.5 mm, 2.6 times as long as wide; color rather dark reddish brown.

Frons convex, transversely impressed on lower third; surface obscurely reticulategranulate, convex area with rather numerous, very large, low, shining granules over more than central half; vestiture fine, sparse, inconspicuous except more abundant along epistoma. Antennal club broadly oval; sutures 1 and 2 strongly procurved, 1 almost reaching middle.

Pronotum 1.1 times as long as wide; as in simplex except sides weakly arcuate; anterior margin armed by eight coarse serrations; posterior area more strongly reticulate, with isolated granules slightly smaller.

Elytra 1.5 times as long as wide, 1.4 times as long as pronotum; outline as in simplex; striae not impressed, punctures moderately large, rather deeply, not sharply impressed; interstriae almost smooth, with a few obscure, transverse lines, evidently narrower than striae, punctures not clearly defined; each interstriae near declivity with about two low, poorly formed granules. Declivity steep, convex, produced at apex; strial punctures small, deep, confused on lower twothirds; interstriae 1 and 3 weakly elevated, 1 with very small granules on upper two-thirds, 3 with small granules on upper third, 9 rather strongly elevated on basal half, its summit subserrate, a rather broad impression between 9 and costal margin. Subglabrous; very sparse, short, fine hair on some specimens.

Female.-Similar to male except frons flattened on at least median half, transvrse impression absent, surface reticulate, dull, with rather abundant, small, deep punctures and fine, short, abundant hair; serrations on anterior margin of pronotum smaller, irregular; strial punctures on disc smaller, not as deep, sharply defined; tubercles on declivity evidently slightly smaller.

Distribution.- Jalisco to Michoacán.
MEXICO: Jalisco: Volcán Colima, 23-VI-65, 2500 m , No. 102; S. L. Wood. Michoacán: Zirimicuaro, 2-XI-80, $1350 \mathrm{~m}, \mathrm{~T} . \mathrm{H}$. Atkinson.

Biology.- As described for the genus. Specimens were taken from a branch of a leguminous tree.

Notes. - The above treatment was based on the type series of 14 specimens.

## 14. Hylocurus ruber Wood

Hylocurus ruber Wood, 1956, Canadian Ent. 88:142 (Holotype, male; 32 km NE Ciudad del Maís. San Luis Potosí, Mexico; Snow Ent. Mus., Univ. Kansas)
Diagnosis.- This species resembles simplex Blandford, although the relationship may be rather remote; it is distinguished by characters summarized in the above key.

Male.- Length 2.3-2.6 mm, 2.5 times as long as wide; color dark reddish brown.

Frons broadly convex, a shallow, transverse impression just above epistoma; surface obscurely reticulate, deeply, rather coarsely punctured except rather coarsely granulate at center; vestiture of coarse, short, rather abundant setae uniformly distributed. Antennal club elongate-oval; sutures 1 and 2 moderately procurved.

Pronotum 1.1 times as long as wide; essentially as in simplex except posterior area with fine granules extending almost to base with moderately large, shallow punctures intermixed.

Elytra 1.5 times as long as wide, 1.3 times as long as pronotum; outline about as in rudis; striae moderately impressed toward declivity, punctures rather small and shallow at base, coarse and very deep toward declivity; interstriae as narrow or narrower than striae, smooth, shining, convex, fine punctures widely spaced, replaced by nodules at base of declivity on all interstriae. Declivity steep, convex, produced at apex; surface
smooth, shining, all striae rather coarsely punctured in rows; interstriae 1,3, and 9 moderately elevated, $2,4,5,6$, and 8 each with one or two large, rounded nodules at base, 1 with moderately small, pointed denticles to apex, 3 with large pointed denticles to junction with 9,7 with five nodules, 9 with a series of contiguous nodules to junction with 5 . Vestiture largely confined to declivital area, of long, slender, interstrial scales; absent from central face of declivity except on 1 and 3.

Female.-Similar to male except frons flattened, with dense, uniformly short pubescence over broad area; anterior margin of pronotum more finely, less regularly serrate; strial punctures on disc slightly smaller, interstrial nodules much smaller.

Distribution.- San Luis Potosí.
Mexico: San Luis Potosí: Los Abritos ( 32 km NE Ciudad del Mais), 18-VI-53, Robinia, S. L. Wood.

Biology.- As described for the genus.
Notes.- The above treatment was based on four paratypes.

## 15. Hylocurus hirtellus (LeConte)

Fig. 147

Micracis hirtellus LeConte, 1876, Proc. Amer. Philos. Soc. 15:369 (Holotype, female; Southern California: Mus. Comp. Zool., 1021)
Hylocurus crinitus Blackman, 1943, Proc. U.S. Nat. Mus. 93:347 (Holotype, male; Orange, California; U.S. Nat. Mus., 56401); Bright, 1966, Pan Pacific Ent. 42:304. Synonymy
Diagnosis.- Except for the antenna, protibia, and elytral denticles, this species might easily be confused with Micracis species. Within Hylocurus it might be confused with femineus Wood or effeminatus Wood, except that the sparse tubercles on interstriae 3 continue to the junction with interstriae 9.

Male.- Length 1.4-1.8 mm, 2.9 times as long as wide; very dark brown to almost black.

Frons broadly convex, a distinct transverse callus near middle, a slight, transverse impression just above epistoma; epistomal area shining, upper area rather coarsely granulatepunctate; vestiture rather sparse, moderately coarse, long. Antennal club oval; sutures 1 and 2 moderately, asymmetrically procurved.

Pronotum 1.1 times as long as wide; widest just behind middle, sides moderately arcuate on basal two-thirds, rather narrowly rounded in front; anterior margin somewhat irregularly armed by six to eight coarse teeth; posterior area reticulate, with rather abundant, close, small, isolated, shining granules. Vestiture of rather abundant, fine, long hair.

Elytra 1.9 times as long as wide, 1.7 times as long as pronotum; outline as in rudis; striae very feebly impressed, punctures coarse, rather deep; interstriae shining, almost as wide as striae, anterior margins of punctures raised on basal .half, distinctly, finely granulate toward declivity. Declivity steep, convex, apex acutely produced; strial punctures smaller than on disc, distinct; interstriae 1 and 3 very feebly elevated, 9 moderately elevated, 1 finely, 3 more coarsely, irregularly tuberculate, tubercles on 3 attain junction with 9 ; interstriae 5,7 , and 8 each with about two to four small tubercles near base, others with occasional small granules. Vestiture of rows of fine, rather abundant, strial and interstrial hair, that of interstriae much longer.

Female.-Similar to male except frons flattened, with a dense patch of fine, long, yellow hair on central half on upper twothirds; anterior margin of pronotum almost unarmed; discal interstriae not as irregular; declivital tubercles somewhat more abundant; vestiture evidently finer, slightly shorter.
Distribution.- Washington to Baja California.

USA: California: Alameda Co., Arcata, Berkeley, Contra Costa Co., Eureka, Fieldbrook, Los Angeles, Mill Valley, Mt. St. Helena, Mt. Tamalpais, Monterey Co., North Hollywood, Oakland, Orange, Palo Alto, Pasadena, Riverside Co., Santa Ana, Scotia, Solano Co., Ventura Co. Oregon: Portland. Washington: Hobart in King Co. MEXICO: Baja California: Santa Domingo.

Hosts.- Alnus sp., Arbutus menziesii, Ceanothus sp., Populus sp., Rhus sp., Salix spp. Bright (1973:64) adds Myrica, Quercus, Rhamnus, Umbellularia.

Bıology.- Essentially as described for the genus.

Notes.- The above treatment was based on the holotypes of hirtellus and crinitus and on 142 other specimens.

## 16. Hylocurus longipennis Wood

Hylocurus longipennis Wood, 1979, Great Basin Nat. 39:141 (Holotype, male; 5 km W El Salto, Durango, Mexico: Wood Coll.)
Diagnosis.- This species is distinguished by the slender body form and by other characters cited below. Although it is more closely allied to hirtellus (LeConte) than to other known species, the relationship is not close.

Male.- Length 2.5 mm (females 2.8-3.0 $\mathrm{mm}), 3.1$ times as long as wide; color very dark brown.

Frons with a strong, transverse carina on more than median half midway between level of antennal insertion and upper margin of eyes; surface concealed by pronotum above carina, smooth, shining, with small punctures at sides and below. Antenna about as in hirtellus except club slightly longer, wider, with sutures slightly more strongly procurved.

Pronotum 1.2 times as long as wide; about as in hirtellus except disc longer, more strongly reticulate, with subcrenulate tubercles almost twice as large.

Elytra 2.0 times as long as wide, 1.7 times as long as pronotum; sides straight and parallel on basal four-fifths, rather abruptly, serrately tapered to strong, apical mucro; striae not impressed, punctures rather coarse, deep, spaced by diameter of a puncture; interstriae slightly narrower than striae, smooth, shining, punctures small, close, their anterior margins slightly elevated, more strongly so near declivity. Declivity very steep, convex; about as in hirtellus except smoother, more brightly shining, tubercles at base slightly larger, broader, interstriae 3 without tubercles below junction with 7, 9 higher and without tubercles on its posterior half; costal margin near apex finely serrate. Vestiture much as in hirtellus except interstrial setae at base of declivity longer, coarser, strial setae much shorter.

Female.-Similar to male except frons without a carina, an indefinite callus in its place, upper surface with indefinite punctures and fine, sparse granules, vestiture rather sparse; tubercles at base of declivity finer.

Distribution.- Durango.
MEXICO: Durango: El Salto, 7-V1-65, 2500 m , No. 41, Quercus branch, S. L. Wood.

Notes.- The above treatment was based on the type series of four specimens.

## 17. Hylocurus femineus Wood

Hylocurus femineus Wood, 1959, Great Basin Nat. 19:59
(Holotype, male; Miller Canyon, Huachuca Mts., Arizona; Wood Coll.)
Diagnosis.- This species is distinguished from the allied effeminatus Wood by the larger size, by the smoother, shining pronotal disc, by the finer elytral setae, and by the more nearly flattened female frons, which is more densely, more extensively pubescent.

Male.- Length 2.2-2.5 mm, 2.3 times as long as wide; color almost black.

Frons convex above, a conspicuous transverse carina at upper level of eyes on median half, rather strongly, transversely impressed below carina; surface densely, rather coarsely punctured above, finely punctured and transversely etched below; vestiture sparse, fine, limited to lateral areas of impression. Antennal club subcircular; sutures 1 and 2 rather weakly procurved.

Pronotum 1.05 times as long as wide; essentially as in simplex except posterior area largely shining (reticulate in Michoacán series), with isolated granules to base, most granules with a shallow puncture on anterior margin, granules larger toward summit. Vestiture of fine, sparse hair.

Elytra 1.4 times as long as wide, 1.3 times as long as pronotum; outline about as in simplex; striae very feebly impressed, punctures rather small, deep, some of them connected by longitudinal lines; interstriae wider than striae, smooth, with occasional transverse lines, punctures small, uniseriate. Declivity very steep, broadly convex, produced at apex; strial punctures slightly smaller than on disc, in rows; interstriae 1 with a few minute granules, $2,4,5$, and 6 with one or two tubercles at base, 3 and 8 with tubercles reaching middle of declivity, 9 rather strongly elevated, subserrate, with one or two fine granules between apex of elevation and terminal mucro. Vestiture of moderately coarse hair at base of declivity, few setae on declivital face.

Female.- Similar to male except frons flattened, carina absent, broadly, rather densely pubescent; anterior margin of pronotum finely serrate; elytral dise smoother;
major tubercles on declivital interstriae 1 and 3 slightly larger, others smaller, 9 less strongly elevated; vestiture finer, more generally distributed.
Distribution.- S Arizona to Michoacán.
USA: Arizona: Miller Canyon, Huachuca Mts., 22-VIII-58, S. L. Wood. MEXICO: Michoacán: PatzcuaroArio de Rosales km 32, 31-X-80, S-I29, Quercus, T. H. Atkinson.
Biology.- As described for the genus. The host was thought to be a small, uprooted Aesculus sp., but native representatives of this genus are unknown at the type locality.
Notes.- The above treatment was based on the type series of six specimens.

## 18. Hylocurus effeminatus Wood

 Fig. 145Hylocurus effeminatus Wood, 1956, Canadian Ent. 88:143 (Holotype, male: 8 km NW Totolapan, Oaxaca, Mexico; Snow Ent. Mus., Univ, Kansas)
Diagnosis.- This species is distinguished from the allied femineus Wood by the smaller size, by the dull, reticulate pronotal disc, by the coarser elytral setae, and by the transverse, female frontal callus.
Male.- Length $1.7-2.1 \mathrm{~mm}, 2.5$ times as long as wide; color almost black.

Frons as in femineus except vestiture more conspicuous. Antennal club oval; sutures 1 and 2 feebly arcuate.

Pronotum 1.1 times as long as wide; as in femineus except sides almost straight and parallel on basal half, and discal area reticulate, dull, without punctures.

Elytra 1.4 times as long as wide, 1.3 times as long as pronotum; outline as in femineus; striae very feebly impressed, punctures rather small, deep; interstriae as wide as striae, smooth, devoid of lines, punctures small, widely spaced. Declivity steep, convex, acuminate at apex; striae and tubercles essentially as in femineus except tubercles average smaller in size and very slightly more numerous. Vestiture largely confined to declivital base, consisting of interstrial scales; each scale about four to six times as long as wide.

Female.- Similar to male except frontal carina poorly developed, represented by a transverse callus bearing several coarse granules, vestiture sparse, limited to central area; anterior margin of pronotum less coarsely serrate; declivital tubercles averaging slightly
larger; elytral vestiture much more slender and more widely distributed.

Distribution.- Oaxaca.
MEXICO: Oaxaca: 6 km N Totolapan, 3-vil-53, 20-V1-67, 1100 m, Nos. 61, 63, S. L. Wood: 30 km SE Cameron, 21-VI-67, leguminous tree, S. L. Wood.

Host.- Leguminous trees.
Biology.-As described for the genus.
Notes. - The above treatment was based on 8 paratypes and on 64 other specimens.

## 19. Hylocurus schwarzi Blackman

Hylocurus schwarzi Blackman. 1928. Bull. New York St. Coll. For., Syracuse, Tech. Pub. 25:189 (Holotype, male; Victoria, Texas; U.S. Nat. Mus., 27132)

Diagnosis.- This species is very similar to effeminatus Wood, but it is distinguished by characters included in the following description.

Male.- Length $2.2 \mathrm{~mm}, 2.4$ times as long as wide; color almost black.

Frons convex, weakly, transversely impressed above epistoma and in median area; entirely devoid of transverse carinate elevation; surface reticulate-granulate with low, subaciculate rugae in lateral areas; vestiture sparse, inconspicuous.

Pronotum 1.03 times as long as wide; as in effeminatus but slightly more shining.

Elytra 1.4 times as long as wide; outline about as in effeminatus but stouter; strial punctures deeper, transversely larger than effeminatus; interstriae weakly convex, on posterior fourth of disc each with row of rounded nodules larger and more broadly rounded than in effeminatus. Declivity about as in effeminatus except interstriae 2 not impressed, bearing a row of very small tubercles to middle, 3-8 all armed by similar, larger, rounded tubercles, those on 3 and 7 continuing almost to middle of declivity, others end on upper fourth. Vestiture as in effeminatus except scales narrower at their apices than at bases, each about six to eight times as long as wide.

Distribution.-S Texas.
USA: Texas: Victoria, 27-H1, E. A. Schwarz.
Notes.- The above treatment was based on the holotype and on one paratype.

## 20. Hylocurus errans Blandford

Hylocurus crrans Blandford, 1898, Biol. Centr. Amer., Coleopt. $4(6): 224$ (Lectotype, male; "Mexican"
tobacco refuse, but probably from Brazil; British Mus. Nat. Hist., present designation)
This species was found at Paris in "Mexican" tobacco refuse. Virtually all of the Blandford species named from that material that have now been identified in the American fauna, are from Brazil, not Mexico. Until this species can be identified in the Central American or in the Mexican fauna, it should be regarded as a Brazilian species.

The first specimen in the syntypic Blandford series has been labeled "Type," although it has never been so designated. 1 here designate this male as the lectotype of errans Blandford.

## 21. Hylocurus rivalis Wood

Hylocurus ritalis Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):16 (Holotype, male; 5 km or 3 miles N Suchixtepec, Oaxaca, Mexico; Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from schwarzi Blackman by the serrate male declivital interstriae 9 , with the nodules on all interstriae higher and slightly closer, by the numerous, strong, irregularly transverse, interstrial lines, and by the more strongly ru-gose-reticulate pronotal disc. It is probably more closely related to effeminatus Wood.

Male.- Length 2.1-2.7 mm, 2.8 times as long as wide; color very dark reddish brown, some specimens almost black.

Frons as in effeminatus, including transverse elevation. Antennal club distinctly larger than in effeminatus. Pronotum as in effeminatus.

Elytra 1.8 times as long as wide; outline similar to effeminatus; striae not impressed, punctures moderately large, deep; interstriae slightly wider than striae, shining, with numerous, irregular, coarse, transverse lines giving interstriae a subcrenulate appearance, some of low, transverse ridges continuing across striae; moderately high, rounded nodules near declivity on all interstriae. Declivity steep, convex, contours about as in schwarzi; striae 1 and 2 continuing to base of mucro; base of each interstriae with three to five rounded nodules, largest as high as wide, 1,3 , and 7 with small, pointed tubercles to middle of declivity, tubercles on 2 and 4 extending to upper third, those on 5,6 , and 8
ending on upper fourth, 9 moderately elevated about as in schwarzi but with small nodules to apex of elevation. Vestiture more abundant than in schwarzi, of rows of minute strial hair, and rows of delicate, coarse, pointed bristles of same texture as schwarzi; bristles longest near base of declivity, each of longest bristles longer than distance between rows, more closely spaced within a row.

Female.- Similar to male except frons devoid of transverse elevation; transverse lines and subcrenulate ridges on elytral dise poorly developed; interstrial nodules much less than half as high, extending almost to middle of disc; declivital tubercles smaller; vestiture finer.

Distribution.- Oaxaca.
MEXICO: Oaxaca: 5 km or 3 miles N Suchixtepec on Highway 175, 4-VI-71, 3000 m , Pinus, D. E. Bright.

Notes.- The above treatment was based on the type series of 54 specimens.

## 22. Hylocurus parkinsoniae Blackman

Hylocurus parkinsoniae Blackman, 1922, New York St. Coll. For., Syracuse, Tech. Pub. 22(5):142 (Holotype, male; Ray, Arizona; U.S. Nat. Mus., 26629)
Diagnosis.- This species is somewhat intermediate between the group of species having the male circumdeclivital interstrial spines all of equal length and the group having them alternate between long and short spines. In this species spine 5 (and occasionally 3 ) is slightly longer than the others.

Male.- Length $1.7-2.3 \mathrm{~mm}, 2.5$ times as long as wide; color dark brown to almost black.

Frons convex above, abruptly, moderately, transversely impressed on lower third; surface of upper area coarsely, very closely punctured, lower area with fine punctures and some transverse striations; vestiture fine, sparse, largely confined to impressed area. Antennal club subcircular; sutures 1 and 2 moderately procurved.

Pronotum 1.1 times as long as wide; as in effeminatus except posterior area subshining, granules decreasing in size posteriorly, some of them with shallow punctures on their anterior sides.

Elytra 1.4 times as long as wide, 1.3 times as long as pronotum; sides straight, diverging very slightly to declivital base, then abruptly converging, a conspicuous notch at apex of
elevated interstriae 9 , with broad, subacute, produced apex mucronate; striae weakly impressed, punctures moderately large, deep; interstriae shining, convex, as wide as striae, punctures rather fine, uniseriate, rather close, each ending precipitously at base of declivity in a large, blunt tubercle. Declivity very steep, subtruncate, face broadly convex, with a circumdeclivital ring of large tubercles, produced at apex; strial punctures clearly impressed, in rows, those near base coarse, becoming finer toward apex; tubercles or blunt spines 1 to 8 in circumdeclivital ring of equal length, not projecting, except 5 longer (sometimes 3 also), 3, 5 , and 7 usually with a supplemental tubercle immediately below spine and on 3 and 5 sometimes joined to it, 9 strongly elevated and ending abruptly well before apex; interstriae 3 with two coarse tubercles on middle third, 1 with a dozen or more fine, pointed tubercles; surface subshining. Vestiture confined to declivital base and tubercles on face; consisting of coarse bristles.

Female.- Similar to male except frons flattened, very finely punctured, with rather abundant, coarse, moderately long, subplumose setae on central two-thirds; anterior margin of pronotum less coarsely serrate; tubercles on pronotal disc larger, punctures almost obsolete; circumdeclivital spines replaced by a series of small granules; declivity more convex, strial punctures of equal size, interstriae 9 less strongly elevated; vestiture finer, more generally distributed.

Distribution.- California to Texas.
USA: Arizona: Fort Yuma, Mesa, Ray, Sabino Canyon, Santa Catalina Mts. California: Mecca, Palo Verde. Texas: Brownsville, Columbus, Davis Mts., Hidalgo Co., Southmost, Victoria.

Hosts.- Celtis laevigata, Cercidium microphyllum, C. floridum, Condalia obtusifolia, Mimosa sp., and Quercus sp.

Brology.- As described for the genus.
Notes.- The above treatment was based on the holotype and on 172 other specimens.

## 23. Hylocurus cancellatus Blandford

Hylocurus cancellatus Blandford, 1898, Biol. Centr. Amer., Coleopt. 4(6):221 (Lectotype, male; Quiché Mts., Guatemala: British Mus. Nat. Hist., present designation)
Diagnosis.- This species is distinguished from medius Wood by the larger size, by the
black color, by the much coarser deeper strial punctures on the male disc, by the steeper declivity, by the different arrangement of minor tubercles on the declivital face, and by other characters.

Male.- Length 2.6-2.9 mm, 2.5 times as long as wide; color very dark brown to black.

Frons convex, rather strongly, transversely impressed below carina; a conspicuously elevated, transverse carina slightly below upper level of eyes occupying median half; surface shining rather coarsely granulate-punctate above carina, lower area smooth, shining, impunctate on median half, finely punctured laterally; vestiture fine, sparse, inconspicuous except along epistoma. Antennal club with sutures more strongly procurved than in allied species.

Pronotum 1.3 times as long as wide; essentially as in microcornis Wood.

Elytra 1.8 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal three-fourths, slightly wider at base of declivity, abruptly narrowed at base of declivity, acutely mucronate behind; striae weakly impressed, punctures very deep, rather small at base, gradually increasing in size toward declivity, those near declivity at least three times larger than those at base; interstriae shining, three times as wide as striae at base, half as wide near declivity, punctures small, sparse, obscure; declivital margin abrupt, margin armed by a circumdeclivital ring of equal, nonprojecting, coarse, blunt tubercles. Declivity steep, moderately convex; striae distinctly marked by rows of punctures to near apex, punctures moderately coarse near base, becoming very fine below; interstriae 1 with a row of fine tubercles from base to apex, 2 unarmed, 3 armed by one tubercle just below basal margin and four to five tubercles on lower twothirds, lowest one in line with 9 and with a weak elevation extending to 9,6 and 7 each with two tubercles, 9 rather strongly elevated, ending rather abruptly near but separate from costal margin. Vestiture confined to declivity, of sparse, moderately coarse, rather long hair.

Female.- Similar to male except frontal carina much more poorly developed; frontal vestiture above carina moderately abundant; strial punctures on posterior area of disc only
twice as large as those at base, not as deep as in male; circumdeclivital ring of tubercles not evident, each interstriae with about three small uniseriate tubercles at base of declivity; declivital face as in male except tubercles extend from apex of interstriae 3 to 9 .

Distribution.-Guatemala.
GUATEMALA: Quiché Mts., 5-9700 ft, G. C. Champion.

Notes. - The above treatment was based on four of Blandford's syntypes. The male syntype on the first pin in the Blandford series is here designated as the lectotype of cancellatus Blandford.
24. Hylocurus langstoni (Blackman)

Figs. I48-I 49, I51
Micracis langstoni Blackman, 1920, Mississippi Agric. Expt. Sta. Tech. Bull. 9:26 (Lectotype, female; Agricultural College, Mississippi; U.S. Nat. Mus., 24734 , present designation)
Diagnosis. - This species is distinguished from the allied medius Wood by the smaller interstrial tubercles in the male circumdeclivital ring, with two or more tubercles below the ring on interstriae 5 and 7 , by the rather coarse, uniform strial punctures on the declivity, and by the less strongly impressed, more broadly pubescent female frons, the male frons similar to that of the female.

Male.- Length $1.8-2.3 \mathrm{~mm}, 2.6$ times as long as wide; color very dark brown.

Frons broadly flattened, rather finely punctured, with abundant, erect, coarse, subplumose, moderately long setae. Antennal club subcircular; sutures 1 and 2 weakly procurved.

Pronotum 1.1 times as long as wide; as in effeminatus except basal area with shallow punctures at anterior margin of granules.

Elytra 1.5 times as long as wide, 1.4 times as long as pronotum; outline about as in effeminatus; dise as in parkinsoniae except interstriae feebly convex, punctures rather widely separated, tubercles in circumdeclivital ring much smaller. Declivity very steep, broadly convex, apex produced; strial tubercles coarse, deep, in rows, only slightly larger toward base; interstriae 1 with fine, irregular granules to apex, 3 with about four larger, pointed tubercles to middle of declivity, 5 and 7 each with two tubercles below circumdeclivital ring, 9 strongly elevated,
ending abruptly at posterior end. Vestiture largely confined to declivital base and at tubercles on declivital face; consisting of stout bristles.

Female.- Similar to male except frons slightly impressed; anterior margin of pronotum minutely serrate; circumdeclivital ring of tubercles absent, other tubercles smaller; vestiture more generally distributed, finer.

Distribution.- Texas to Maryland and Florida.

USA: Florida: Lake Co. Maryland: Brunswick, Plummer's Island. Mississippi: Agricultural College. South Carolina: St. Catherine Island. Texas: Beeville, Brownsville, Columbus. Gillespie, Karnes City. Virginia: Lovettsville, Rocky Point in Franklin Co.

Host.- Celtis pallida, C. sp., Ulinus sp.
Biology.-As described for the genus.
Notes.- Blackman based this species on a long series of syntypes. He selected a female from this series and labeled it as the type and placed it in the type collection at the U.S. National Museum without validating his action. I here designate that female as the lectotype of langstoni Blackman. The above treatment was based on the lectotype and on 71 other specimens.

## 25. Hylocurns medius Wood Fig. 145

Hylocurus medius Wood, 1956, Canadian Ent. S8: I44 (Holotype, male; 8 km W Antiguo Morelos, Tamaulipas, Mexico; Snow Ent. Mus., Univ. Kansas)
Diagnosis.- This species is distinguished from the allied langstoni (Blackman) by the much larger tubercles in the male circumdeclivital ring, by the absence of male frontal vestiture, and by other characters mentioned in the above key.

Male.- Length $1.8-2.2 \mathrm{~mm}, 2.4$ times as long as wide; color very dark brown.

Frons convex, a transverse, granulate callus just below upper level of eyes; surface finely subrugose, finely, shallowly, closely punctured; vestiture of sparse, stout, setae of moderate length. Antennal club subcircular; sutures 1 and 2 poorly formed, moderately procurved.

Pronotum as in effeminatus.
Elytra 1.4 times as long as wide, 1.3 times as pronotum; outline as in parkinsoniae; dise as in parkinsoniae except some strial punctures connected by longitudinal lines, a few transverse lines cross interstriae; circum-
declivital spines as in parkinsoniae except all of equal length. Declivity as in parkinsoniae except submarginal tubercles on interstriae 3 ,

5,7 , and occasionally on others distinctly below circumdeclivital ring. Vestiture shorter, more nearly scalelike than in parkinsoniae.

Fig, 151. Hylocurus, dorsal aspect: 31, langstoni, male, 32, same, female; 33, harnedi, male, 34, same, female. (After Blackman 1922:pl. VI.)

Female.-Similar to male except frons very shallowly concave, with a dense patch of rather long, coarse, subplumose setae on central two-thirds; anterior margin of pronotum minutely serrate; circumdeclivital ring of tubercles absent; strial punctures on declivity of equal size, tubercles smaller, vestiture finer and more generally distributed.

Distribution.- Tamaulipas to San Luis Potosí.
Mexico: San Luis Potosí: Pujal, 20-vi-53, S. L. Wood. Tannaulipas: 8 km W Antiguo Morelos, 20-VI-53. S. L. Wood.

Brology.-As described for the genus.
Notes.- The above treatment was based on 16 paratypes.

## 26. Hylocurus microcornis Wood

Hylocurus microcornis Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2):45 (Holotype, male: 26 km E Texmelucan, Puebla, Mexico: Wood Coll.)
Diagnosis.- This species is distinguished from the allied equidens Wood by characters summarized in the above key.

Male.- Length 2.5-2.9 mm, 2.7 times as long as wide; color black.

Frons weakly convex, ascending slightly toward epistoma; surface very closely, subgranulately punctured, with a transverse carina occupying median third at level immediately below upper level of eyes. Antennal club very slightly longer than distance equal to width of eye, 1.7 times as long as wide.

Pronotum 1.06 times as long as wide; widest on basal third, sides weakly arcuate and converging slightly to anterior third, then rather narrowly rounded in front; anterior margin armed by eight teeth; anterior slope asperate, posterior area closely tuberculate, interstriae rather coarsely reticulate; vestiture inconspicuous, hairlike.

Elytra 1.9 times as long as wide, 2.0 times as long as pronotum; striae slightly impressed on posterior third, punctures deep, small at base, increasing in size toward declivity; interstriae as wide as striae, weakly convex except near declivity, terminating abruptly at margin of declivity in a blunt, nonprojecting spine, punctures rather fine, uniseriate. Declivity abrupt, somewhat convex within ring of subequal marginal tubercles (except those on 1 smaller); costal margin near apex subserrate; strial punctures impressed, in rows;
interstriae shining, 1 bearing nine small pointed tubercles, 3 with three small granules, lateral interstriae unarmed, mucro well developed, reticulate. Vestiture confined to declivity, consisting of minute strial hair and rather long, slender bristles.

Female.-Similar to male except frons above more nearly flattened, slightly more protuberant below, ornamented on median two-thirds by a conspicuous tuft of rather long, yellow hair from near epistoma to vertex, median area immediately above epistoma smooth and shining, remaining area rather finely reticulate-granulate, punctures obscure, carina absent; anterior margin of pronotum unarmed; tubercles on declivital margin absent; declivital striae as on disc, interstriae except 2 armed by fine tubercles, those on $1,3,7$, and 9 extending to middle of declivity, others ending on upper fourth; elytral vestiture finer, shorter, extending to disc.

Distribution.- Puebla.
MEXICO: Puebla: 26 km E Texmelucan, 13-VI-67, 2900 m. No. 29, Salix, S. L. Wood.
Biology.-As described for the genus.
Notes.- The above treament was based on the type series of eight specimens.

## 27. Hylocurus equidens Wood Fig. 145

Hylocurus equidens Wood, 1956, Canadian Ent. 88:144 (Holotype, male; Los Abritos, 32 km NE Ciudad del Mais, San Luis Potosí, Mexico; Snow Ent. Mus., Univ. Kansas)
Diagnosis.- Refer to the above key to distinguish this species from the closely allied microcornis Wood.

Male.- Length $1.8-2.0 \mathrm{~mm}, 2.5$ times as long as wide; color very dark brown.

Frons, antenna, and pronotum as in parkinsoniae except pronotal disc reticulate, with isolated granules to base, punctures absent.

Elytral disc as in parkinsoniae exceot blunt circumdeclivital spines slightly larger, all spines of equal length; declivity steeper. Declivity as in parkinsoniae except less convex, strial punctures near base larger, submarginal tubercles entirely absent except on interstriae 1 and 3; these tubercles as in parkinsoniae except interstriae 3 weakly elevated near center, two tubercles slightly larger; setae much coarser.

Female.- Frons, pronotum, and elytra as in female medius.

Distribution.- San Luis Potosí.
Mexico: San Luis Potosí: Los Abritos, 32 km Ne Ciudad del Mais, 18-VI-53. S. L. Wood.
Biology.- As described for the genus.
Notes.- The above treatment was based on 12 paratypes.

## 28. Hylocurus disparilis Wood

Hylocurus disparilis Wood, 1971, Brigham Young Univ: Sci. Bull., Biol. Ser. 15(3):29 (Holotype, male; Zamorano, Morazán, Honduras; Wood Coll.)
Diagnosis.- This species is distinguished from inaequalis Wood by the exaggerated development of the male circumdeclivital spines.

Male.- Length $2.2 \mathrm{~mm}, 2.5$ times as long as wide; color very dark brown.

Frons, antenna, pronotum, and elytral disc as in inaequalis Wood except circumdeclivital spines longer, particularly on alternate odd-numbered interstriae, spines 1 and 9 conspicuously longer than others; elytral apex much more slender than in allied species. Declivital face with punctures on lower two-thirds of striae 1 and 2 very small, in rows, all other punctures coarse, deep, confused, becoming much larger toward base: interstriae 3 not elevated, armed by two blunt tubercles.

Distribution.- Honduras.
HONDURAS: Zamorano, Morazán, 18-IV-64, 700 m . No. 558, Ficus glabrata, S. L. Wood.

Biology.- The unique type was taken from a new tumnel in the wood of a small. broken, fig branch.

## 29. Hylocurus alternus Wood

Hylocurus alternus Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. $10(2): 43$ (Holotype, male; 21 km SE Liberia, Guanacaste, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from the rather closely related inaequalis Wood, by the less strongly developed spines in the circumdeclivital row of the male, and by the distinct rows of strial punctures in lateral areas on the male declivity; and by the less abundant vestiture on the female frons.

Male.- Length $1.7-2.5 \mathrm{~mm}, 2.5$ times as long as wide; color very dark brown, almost black.

Frons convex and granulate above, transversely impressed and punctured below a
transverse carina formed at upper level of eyes by four basally confluent tubercles; vestiture inconspicuous.

Pronotum 1.1 times as long as wide; widest near base, sides feebly arcuate and converging very slightly on basal two-thirds, then rather broadly rounded in front; anterior margin armed by about 12 coarse serrations; summit in front of middle; posterior area subshining, rather finely punctured, posterior margin of each puncture subasperate, more coarsely sculptured toward summit. Vestiture consisting of short, inconspicuous hair.

Elytra 1.4 times as long as wide, 1.2 times as long as pronotum; sides almost straight and parallel to declivital base; profile of posterior margin interrupted by projection of spines on interstriae 9 and 3 and by sutural apex; striae not impressed, punctures large, deeply impressed; interstriae narrower than striae, irregularly, sparsely punctured, each ending posteriorly at declivital margin in a tubercle or spine. Declivity abrupt, very steep; upper and lateral margins armed by a row of tubercles, those on interstriae 2,4 , and 6 distinctly shorter, all tubercles abruptly declivous behind, 9 longer and projecting; declivital face convex, coarsely punctured, with two rather coarse tubercles on interstriae 3 and about four smaller ones on middle third of 1 ; apex narrowly acuminate. Vestiture consisting of short, stout, bristles.

Female.- Similar to male except frontal carina absent, frons more finely sculptured; anterior margin of pronotum finely serrate; elytra not abruptly declivous, without a marginal row of tubercles on declivity; each interstriae bearing about three to five small tubercles on upper or lateral half of declivity.

Distribution. - Costa Rica.
COSTA RICA: 21 km or 13 miles SE Liberia, Guanacaste, $10-\mathrm{Vl}-66,50 \mathrm{~m}, \mathrm{~S} . \mathrm{L}$. Wood.

Biology. - As described for the genus.
Notes. - The above treatment was based on the type series of 41 specimens.

## 30. Hylocurus inaequalis Wood

Fig. 145

Hylocurus inaequalis Wood, 1956, Canadian Ent. 85:146 (Holotype, male; 9 km S Tehuantepec, Oaxaca, Mexico; Snow Ent. Mus., Univ. Kansas)

Diagnosis.- This species is distinguished from the allied alternus Wood by the characters summarized in the above key and in the diagnosis of alternus.

Male.- Length 1.5-2.1 mm, 2.5 times as long as wide; color very dark brown.

Frons with a subcarinate, irregular, transverse row of granules just below upper level of eyes, broadly convex above, transversely impressed below; surface very finely rugose and minutely, rather obscurely punctured above, more finely sculptured below; vestiture moderately abundant. Antenna as in allied species. Pronotum as in alternus.

Elytral dise and declivity as in alternus except odd-numbered spines in circumdeclivital ring projecting about four times or more as far as even-numbered spines and more than twice as far as in alternus, and punctures in lateral areas of declivital face considerably larger, confused, general relief more exaggerated, tubercles on interstriae 3 higher, vestiture similar.

Female.-As in female alternus except frons shallowly concave on median third of lower half, more finely sculptured, more closely pubescent.

Distribution. - Nayarit to Oaxaca.

MEXICO: Colima: 3 km W , No. 136, and 24 km W Armeria, No. 151, 50 m , thorness shrub, S. L. Wood; 53 kim S Colima, 27-VI-65, 700 m , No. 123, shrub, S. L. Wood. Nayarit: 8 km S Rosamorada, 14-VII-65, 100 m , No. 248, Inga paterno, S. L Wood. Oaxaca: 9 km S Tehwantepec, 8-VII-52, Acacia, S. L. Wood.

Hosts.- Acacia sp., Inga paterno, etc.
Brology.- As described for the genus.
Notes.- The above treatment was based on 26 paratypes and on 97 other specimens.

## 31. Hylocurus elegans Eichhoff

 Fig. 152Hylocurus elegans Eichhoff, 1872, Berliner Ent. Zeitschr. 15:134 (Holotype, male; Teapa, Tabasco, Mexico; Brussels Mus.)
Hylocurus minor Wood, 1961, Great Basin Nat. 21:4 (Holotype, female; Finca Alto Bonito, Caicedonia, Valle de Cauca, Colombia; Wood Coll.); Wood, 1972, Great Basin Nat. 32:195. Synonymy
Diagnosis.- This species superficially resembles microcornis Wood and its allies, but it is distinguished in the male by the absence of an abrupt notch at the posterior end of elevated interstriae 9 ; instead interstriae 9 joins the costal margin. In the female the frontal pubescence is limited to the upper half of the facial area and is almost completely divided along the median line into two parts.

Fig. 152. Hylocurus spp., males: A, simplex; B, nodulus; C, elegans.

Male.- Length 1.3-1.8 mm, 2.7 times as long as wide; color very dark brown.

Frons as in alternus Wood except transverse carina continuous, rather well developed. Pronotum as in alternus except punctures absent.

Elytra 1.4 times as long as wide; sides almost straight and parallel on more than basal three-fourths, then abruptly rounded to subacute, rather strongly produced apex; striae feebly impressed toward declivity, punctures moderately coarse, deep; interstriae slightly narrower than striae, weakly convex, punctures moderately convex, rather widely spaced, their anterior margins slightly elevated, interstriae all ending in a circumdeclivital ring of large, rounded nodules of equal length and size at abrupt base of declivity. Declivity very steep, broadly, weakly convex, produced at apex; surface shining; strial punctures larger and in rows toward base, smaller and confused on lower half; a few small, obscure granules on interstriae 1 , two small teeth on 3,9 rather strongly elevated, joining costal margin and continuing to apex as a continuous ridge (allotype of minor with a slight notch at end of interstriae 9 rarely seen in Mexican material). Vestiture largely confined to declivital area, consisting of interstrial scales; each scale about four times as long as wide.

Female.- Similar to male except frons very shallowly, rather narrowly concave below upper level of eyes, convex above, upper area bearing a pair of dense patches of erect, coarse, rather long, yellow, subplumose setae on median half, patches often connected at upper extremities; anterior margin of pronotum unarmed; elytral dise more conservatively sculptured, circumdeclivital nodules absent; declivity more strongly convex, basal area with several interstrial tubercles, two tubercles on interstriae 3 near middle of declivity larger, interstriae 9 ending abruptly, not joining costal margin; declivital scales more slender, longer.

Distribution. - Nayarit to Colombia.
MEXICO: Colima: 3 km W Ammeria, 28-V1-65, 70 mm , No. I36, tree branch: 24 km W Armeria, 30 -VI- $65,30 \mathrm{~m}$, No. 15I, shrub; 6 km S Cihuatlán, 30-VI-65, 70 m , No. 158, tree branch; all by S. L. Wood. Nayarit: Los Corchos, 10-VII-65, 7 m , No. 2II, Inga, and 11-VII-65, 10 m, No. 218, Acacia, S. L. Wood. HONDURAS: Zamorano, Morazán, IS-IV-64, 700 m , No. 546, Acacia pemnatula, S. L. Wood. COSTA RICA: Dominical, 9-VIl-63, 3
m. No. 296, shrubly vine (liana), S. L. Wood. COLOMBIA: Finca Alta Bonito, Caicedonia, Valle de Cuaca, 30-IV-59, vine, J. Restrepo; Finca El Bosque, Caicedonia, Valle de Cauca, VI-59, Coffea, J. H. Losso.

Hosts.- Acacia spp., Inga sp., Coffea arabica, etc.

Brology.- As described for the genus.
Notes.- The above treatment was based on the type series of 12 specimens and on 219 other specimens.

## 32. Hylocurus dissidens Wood

Hylocurus dissidens Wood. 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. I5(3):30 (Holotype, male; Laguna Santa María, Nayarit, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from aberrans Wood by the slightly smaller spines in the male circumdeclivital ring, by the more strongly convex male declivital face, by the more abundant pubescence on the female frons, and by the more strongly procurved suture on the antennal club.

Male.- Length $1.9-2.2 \mathrm{~mm}, 2.7$ times as long as wide; color dark reddish brown.

Frons as in aberrans. Antennal club with sutures moderately procurved. Pronotum as in aberrans except granules in discal area slightly larger, punctures not indicated.

Elytra 1.6 times as long as wide; widest at base of declivity, sides straight on more than basal three-fourths, abruptly, serrately rounded behind, obtusely produced at apex; striae not impressed except near declivital margin, punctures moderately coarse, deep; interstriae almost as wide as striae, smooth, punctures small, sparse; each interstriae ending at margin of declivity in a coarse nodule of equal length, 3-9 acutely pointed on their lateral margins and projecting slightly. Declivity abrupt, very steep, broadly convex, produced behind; strial punctures in rows, those near base of declivity larger, interstriae minutely granulate, 1 slightly elevated to apex and bearing about five small granules on middle third, 3 rather weakly elevated on upper two-thirds, with four closely set, acutely pointed teeth on middle third; interstriae 9 acutely elevated, joining costal margin, but with a very small notch at its apex as it joins costal margin. Glabrous except for a few minute, hairlike setae at declivital margin.

Female.-Similar to male except frons shallowly concave on central half, upper
two-thirds of concavity with dense, erect, coarse, subplumose setae, surface minutely reticulate-granulate, devoid of larger granules; anterior margin of pronotum more finely serrate; strial punctures slightly smaller; circumdeclivital ring of nodules absent, declivity more strongly convex; declivital face similar, more finely sculptured, all interstriae with a few minute granules near base, 9 rather weakly elevated, ending remote from costal margin; vestiture rather widely distributed, sparse, coarse, moderately long.

Distribution.- Nayarit.
MEXICO: Nayarit: Laguaa Santa María, 6-VII-65. $10(K) \mathrm{m}$, No. 197, S. L. Wood.

Biology.-As described for the genus. The host was a large, square-stemmed, thorny, shrubby vine (liana).

Notes. - The above treatment was based on the type series of 21 specimens.

## 33. Hylocurus clarki Wood

Hylocurus clarki Wood, 1979, Great Basin Nat. 39:141 (Holotype, male: between Sicabé and San Miguel Ixtahuacán, San Marcos, Guatemala; Wood Coll.)
Diagnosis.- This species is distinguished from aberrans Wood by the more coarsely tuberculate pronotal disc, by the smaller discal strial punctures, and by the very different male elytral declivity.

Male.- Length 2.3-2.5 mm, 2.4 times as long as wide; color dark reddish brown.

Head about as in aberrans.
Pronotum as in aberrans except dise much more strongly reticulate, rounded tubercles conspicuously larger.

Elytra similar to aberrans except strial punctures smaller, interstriae slightly wider than striae and marked by more numerous transverse lines, declivity with spines in circumdeclivital ring blunt, conspicuously more strongly projecting, particularly on upper half, degree of projection about equal to width of spine, punctures on declivital face confused, vestiture on circumdeclivital ring conspicuously longer, more slender, setae on declivital face short, of stout hair.

Distribution.- Guatemala.
GUATEMALA: Between Sicabé and San Miguel Ixtahuacán, San Marcos, 24-11-72, Pinus tenuifolia, E. W. Clark.

Notes.- The above treatment was based on the type series of two males.

## 34. Hylocurus aberrans Wood

Hylocurus aberrans Wood, 1969, Brigham Young Univ. Sci. Bull., Biol. Ser. 10(2): 44 (Holotype, male; Dominical, Puntarenas, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from the closely allied dissidens Wood by characters summarized in the above key.

Male.-Length 2.0-2.2 mm, 2.6 times as long as wide; color dark reddish brown.

Frons broadly convex, with a slight transverse impression just above epistomal margin; surface finely, regularly granulate. Antennal club with two procurved sutures, 1 extending two-fifths of club length from base, 2 extending four-fifths from base.

Pronotum 1.2 times as long as wide; widest on basal half, sides feebly arcuate, rather broadly rounded in front; anterior margin armed by 16 or more serrations; summit in front of middle; posterior area reticulate, with small, subgranulate punctures of moderate abundance. Vestiture consisting of short, erect scales with a few bristles in asperate area.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel to base of declivity, then slightly wider at middle of declivity; posterior outline interrupted by declivital spines on interstriae 7,8 , and 9 and by short, broad, sutural apex; striae slightly impressed, punctures deep, coarse, much smaller toward base; interstriae about half as wide as striae, punctures on 1 moderately large, others mostly minute. Declivity abrupt, very steep, almost entirely margined by a row of tubercles or spines; tubercles at base of declivity on interstriae 1 and 2 not pointed, abruptly declivous behind, those on 2 to 8 produced into increasingly large and pointed toothlike spines, 9 similar but lower and extending nearer elytral apex than normal for this genus; apex not strongly produced, its margin subserrate, small dentations about half as high as apex of elevation on interstriae 9; central area coarsely punctured, interstriae 3 slightly elevated near center and bearing three small teeth, 1 on lower third gradually elevated to apex and finely serrate. Vestiture consisting of a few stout bristles or scales at margin and on interstriae 1 and 3 .

Female.- Similar to male except frons less strongly convex, finely punctured, ornamented by stout, short, rather sparse setae; scape flattened and bearing a tuft of long, coarse setae; anterior margin of pronotum almost unarmed; elytra more finely sculptured, declivity convex, without marginal ring of tubercles, striae regularly punctured, oddnumbered interstriae bearing several rounded granules; rows of broad scales on upper half of all declivital interstriae.
Distribution.- Costa Rica.
COSTA RICA: Dominical, Puntarenas, 9-Xll-63, 3 m . S. L. Wood.

Brology.- Presumably as described for the genus; the tunnel was not fully developed.

Notes.- The above treatment was based on the holotype and allotype.

## Hylocurus retusipennis Blandford

Hylocurus retusipennis Blandford, 1898, Biol. Centr. Amer., Coleopt. $4(6): 223$ (Holotype, male; "Mexican" tobacco refuse intercepted at Paris; British Mus. Nat. Hist.)
It has been assumed since its description that retusipennis Blandford was a Mexican species. The type is identical to a series of males from southern Brazil (Santa Catarina) that have been in my collection under the name Hylocurus bidentatus Schedl, as determined by Schedl. The suspected synonymy has not been confirmed.

## 35. Hylocurus punctatorugosus (Schedl)

Micracis punctatorugosus Schedl, 1948. Rev. de Ent. 19:575 (Holotype, female: Huetamo, Michoacán, Mexico; Schedl Coll.)
Diagnosis.- The antennal scape and certain other features superficially resemble certain species of Micracis; however, the frons, protibia, elytral declivity, and other features clearly indicate an affinity to aberrans Wood and to the South American singularis Wood, dimorphus (Schedl), and allied species. It is the only Central American species in this section of the genus with a triangularly expanded, elaborately pubescent antennal scape.

Female.- Length $2.4 \mathrm{~mm}, 3.0$ times as long as wide; color rather dark reddish brown.

Frons flat on slightly more than median half from level of antennal insertion to well
above eyes, epistoma rather strongly ascending to margin; flattened area smooth, brightly shining, impunctate, its lateral margins with a rather dense row of very fine, moderately long hair from epistoma to upper level of eyes (upper areas concealed by pronotum). Scape narrowly triangular, one-fourth of its length projecting beyond insertion of pedicel; ornamented by a tuft of long hair arising from anterior margin from base to level of insertion of pedicel, a separate tuft arising from apex of extended portion; longest setae more than three times length of scape. Antennal club about 1.5 times as long as wide, very similar to some Micracis.

Pronotum 1.3 times as long as wide; sides straight and parallel on more than basal half; summit at middle; anterior slope asperate as in allied species, anterior margin rather narrowly rounded, armed by six serrations; posterior areas almost smooth, shining, punctures rather coarse, moderately deep. Vestiture hairlike.

Elytra 1.9 times as long as wide, 1.5 times as long as pronotum; outline as in female aberrans; disc about as in aberrans except strial punctures slightly smaller. Declivity convex, rather steep, mucro rather poorly developed; surface smooth, shining; striae slightly impressed, punctures about as on disc; alternate interstriae each armed by a row of fine, pointed tubercles, 9 subcostate, unarmed, and joining costal margin; rugosereticulate at mucro. Vestiture of fine, short strial hair and rows of fine, erect interstrial bristles on disc and declivity, each as long as distance between rows.

Distribution.- Michoacán.
MEXICO: Michoacán: Huetamo, 328 m .
Notes.- The above treatment was based on the holotype.

## Hylocurus beckeri Hedquist

Hylocurus beckeri Hedquist, 1954, Ent. Tidskr. 75:8 (Holotype, female; Chimaltenango, Guatemala; Naturhistoriska Riksmuseet, Stockholm)
Diagnosis.- This species was based on three females, two of which are virtually unrecognizable; the holotype also is in rather poor condition. The slender form suggests a relationship to the elegans species group, but the granulate, nonpubescent frons and the fine, hairlike declivital vestiture cannot be
associated with any species presently before me.
Female.- Length $2.0 \mathrm{~mm}, 2.75$ times as long as wide; color very dark brown.

Frons convex, much as in female effeminatus Wood except rounded granules more numerous and more widely distributed, vestiture finer, less abundant.

Pronotum 1.1 times as long as wide; very similar to bicornis (Blackman) except discal area more strongly rugose, tubercles more nearly circular in outline. Elytra as in male bicornis except interstriae 1 with several fine tubercles of equal size, vestiture shorter, finer, two tubercles on interstriae 3 slightly larger.
Distribution.-Guatemala.
GUATEMALA: Chimaltenango, Chimaltenango, 1951, 1250 m, Pinus, G. Becker.
Notes. - The above treatment was based on the type series of three female specimens.

## Hylocurus spinifex Blandford

Hylocurus spinifex Blandford, 1904, Biol. Centr. Amer., Coleopt. 4(6):225 (Lectotype, male; "Mexican"
tobacco refuse, but probably from Brazil; British Mus. Nat. Hist., present designation)
Diagnosis.- This aberrant species, named from specimens found at Paris in "Mexican" tobacco refuse, almost certainly does not belong to the Mexican fauma. It probably came from Brazil. There is some doubt that it belongs to Hylocurus, although it shares several characters with that genus. It is unique in having the antennal insertion on the frons, with the insertions separated by slightly more than half the distance between the eyes. The scape is unusually long, the club apparently of the Hylocurus type, but it can be seen only at an extreme angle on the type. The anterior margin of the pronotum is serrate, the pronotal disc is deeply punctured, the declivity is as illustrated by Blandford except the apex is emarginate, not mucronate, and the emargination is filled by the peculiar apex of sternum 5 ; the tibiae are unusually small.

The first syntype in the Blandford series, a male, has been labeled "Type," although it has never been so designated. I here designate this male as the lectotype of spinifex Blandford.

## Tribe CACTOPINiNi

Cactopinae Chamberlin, 1939, The bark and timber beetles of North America, p. 243 (Type-genus: Cactopinus Schwarz, 1899)

Anatomical features.- The frons is sexually dimorphic, with the male impressed and armed by a pair of (usually confluent) hornlike spines of large to enormous size, the female is convex and unarmed, the posterodorsal area of the head is slightly produced caudad, the eye is small and entire, the antennal funicle is 5 -segmented, the club is almost conical to rather strongly flattened, the pronotum is asperate, its summit is at or near the posterior margin, the procoxae are contiguous, and the elytral sculpture is somewhat unique and almost always coated by a film of host origin.

Biological features.- All species are monogamous, and those species in hosts other than cactus are phloeophagous. Those in cactus breed in dry tissue immediately below the epidermis, or (hubbardi Schwarz) in scar tissue in deep wounds. The parental galleries consist of an irregular cave, often with indefinite, broad egg galleries. The eggs are deposited individually in niches. Larval mines may be individual or lost in a criss-crossing maze. Successive generations have been bred in the same piece of dry cactus for four years. Symbiotic relationships with fungi have not been reported.

Taxonomy.- This unique tribe is restricted to the Mexican plateau region. Its nearest relationships appear to be with Micracini, but that connection is remote. They are exceedingly rare.

## Genus CACTOPINUS Schwarz

Cactopinus Schwarz, 1899, Psyche 8 (Suppl. 1):11 (Typespecies: Cactopinus hubbardi Schwarz, monobasic)
Cactopinorus Bright, 1967, Canadian Ent. 99:918 (Typespecies: Cactopinus cactophthorus Wood, original designation); Wood, 1969. Coleopterists Bull. 23:42. Synonymy

Diagnosis.- This unique genus is remotely related, at best, to other known genera of Scolytidae. The paired epistomal male horns, the distinctive antenna, pronotum, and elytra are unmatched in the family.

Description.- Length 1.2-2.3 mm, 2.0-2.6 times as long as wide; color very dark brown to black, often covered by an incrustation; vestiture hairlike except for epistomal brush.

Frons profoundly dimorphic; male with a pair of separate or contiguous epistomal hornlike spines varying from short to half length of body, frontal area moderately to profoundly excavated; female frons simple, unarmed, convex to shallowly concave, vestiture usually sparse. Eye moderately small, finely faceted, anterior margin entire or broadly sinuate. Antennal scape moderately short, slender; funicle 5 -segmented; club very small and slender to rather large and broad, two sutures straight to strongly procurved, indicated by rows of setae. Pronotum with summit well behind middle, projecting behind posterior margin in some species; anterior slope armed by narrow asperities. Scutellum small, laterally compressed, much longer than wide, somewhat depressed. Elytra striate, conservatively to coarsely sculptured; declivity abrupt, usually somewhat bisulcate. Anterior coxae contiguous.

Distribution.- S California and S Utah to Oaxaca; 14 species are known.

Biology.- These monogamous species breed in certain species of giant cacti, rucca, Bursera, Pinus, and Rhus. They excavate an elongate, cave-type tunnel having large, irregulary formed egg niches along its margins. Little effort is made by the beetles to remove frass from their tunnels, thereby making it necessary for them to wallow in the frass. Presumably the male horns were developed
as tactile organs to facilitate excavation of the tunnel or location of his mate. Larval tunnels mine surrounding tissues; ordinarily they are rather long and winding. Apparently
it is common for several successive generations to be completed in a piece of host material without adult emergence between generations.

1. Body stout, 2.0 times as long as wide; male epistomal horns widely separated, space between them at least as wide as one horn; antennal club large, circular, sutures procurved; strial punctures coarse and very deep

- Body more slender, more than 2.2 times as long as wide; male epistomal horns contiguous at least on basal half; antennal club small and oval to large and circular, sutures either straight or procurved; strial punctures smaller, usually not as deep

2(1). Male frons shallowly concave, its upper margin rounded; male horns very short, their height usually not greater than their basal width; lateral convexities on elytral declivity moderate, with striae 2 clearly marked before summit; interstrial nodules on disc continue to base of elytra; Oaxaca; giant cactus; 1.5-1.9 mm

- Male frons broadly, deeply concave, its upper margin abrupt; male horns each three or more times longer than its basal width; lateral convexities of elytral declivity abruptly, strongly elevated, striae 2 obsolete toward summit of lateral elevation; interstrial nodules largely obsolete on basal half of disc; Jalisco; giant cactus; $1.3-1.6 \mathrm{~mm}$

2. mexicanus Wood

3(1). A majority of pronotal asperities on anterior half, including anterior fourth; posteromedian area of pronotum weakly conical, usually not projecting behind posterior margin; pronotal asperities irregular in size, mostly fine, close, abundant; male frons deeply, broadly concave (except excavated but transversely flat to feebly concave in cactophthorus)

- A majority of pronotal asperities on posterior half, anterior fourth usually unarmed; posteromedian area of pronotum strongly projecting over scutellum; pronotal asperities coarse, isolated, comparatively sparse; male frons transversely flat or convex

4(3). Pronotal asperities more widely distributed, supplemented in lateral areas by rounded granules extending to lateral margins; posteromedian margin of pronotum narrowly elevated into a small cone projecting very slightly above scutellum; body never covered by an incrustation

- Pronotal asperities more narrowly distributed on posterior half, lateral areas devoid of granules; posteromedian area not narrowly elevated or produced into a cone; body usually largely covered by an incrustation

| 5(4). Antennal club rather small, distinctly longer than wide, sutures straight; male |
| :--- |
| frons more narrowly excavated, upper half not wider than distance between |
| eyes (except cactophthorus); usually smaller, $1.2-1.9 \mathrm{~mm} . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . ~$ |

- Antennal club rather large, about as wide as long, sutures rather strongly, subangulately procurved; upper half of male frontal excavation distinctly wider than distance between eyes; usually larger, 1.3-2.3 mm

6(5). Male frons strongly excavated but transversely almost flat, anterior margin of eye touching excavation when viewed from lateral aspect; frontal horn of male longer than median length of frontal excavation; strial punctures slightly smaller, not as deep; interstriae slightly wider, punctures fine, somewhat confused; Puebla; giant cactus; $1.2-1.4 \mathrm{~mm}$
3. cactophthorus Wood

- Male frons more narrowly concave, anterior margin of eye not reaching excavation when viewed from lateral aspect; frontal horn of male much shorter than length of frontal excavation; strial punctures slightly larger, deeper; interstriae narrower, punctures somewhat coarser, usually uniseriate

7(6). Discal interstriae uniseriately punctured to margin of declivity; Oaxaca; giant cactus; 1.6-1.9 mm

- Discal interstriae uniseriately, closely, rather coarsely granulate on slightly less than posterior half; Oaxaca; giant cactus; 1.3-1.6 mm

5. granulifer Wood

8(5). Frons devoid of a median carina, sometimes feebly, obtusely raised in male; sutures of antennal club strongly, obtusely bisinuate; elytral punctures and pronotal asperities slightly larger, posteromedian marginal cone on pronotum rather well developed; Puebla to Oaxaca; giant cactus; $1.4-1.7 \mathrm{~mm}$
6. nasutus Wood

- Upper half of frons bearing an acutely elevated median carina in both sexes; sutures of antennal club angulate, 1 acute (more pronounced in male); elytral punctures and pronotal asperities slightly smaller, posteromedian marginal cone on pronotum poorly developed; Hidalgo; giant cactus; 1.5-1.8 mm

7. carinatus Wood

9(4). Strial punctures fine, shallow, interstrial punctures minute, confused; declivity rather gradual, more narrowly sulcate above, elytral apex narrowly rounded behind; lateral convexities of declivity entirely devoid of granules or teeth; San Luis Potosí to Hidalgo; Y'ucca leaves; $1.3-1.5 \mathrm{~mm}$
8. depressus Bright

- $\quad$ Strial punctures rather coarse, deep; interstriae 1,3, and 5 uniseriately granulate to base; elytra broadly rounded behind; declivity steep, rather broadly excavated, lateral convexities each armed by about three to five coarse teeth; Jalisco to Oaxaca; Burscra, etc.; $1.4-1.7 \mathrm{~mm}$

9. spinatus Wood

10(3). Elytral declivity shallowly sulcate, lateral convexities armed by minute granules; elytra rather narrowly rounded behind; male horn shorter than half length of pronotum; body slender, more than 2.5 times as long as wide11

Elytral declivity rather deeply sulcate, lateral convexities armed by small to
very large denticles; elytra very broadly rounded behind; male horn usually
longer than half length of pronotum ........................................................................... 12
11(10). Elytral declivity not sulcate except for feeble impression on interstriae 1 , interstriae l-3 not granulate; Utah to Baja California; Pinus; 1.3-1.5 mm

- Elytral declivity shallowly sulcate, interstriae 1-3 uniseriately, coarsely granulate; S California; Rhus diversalobata, R. trilobata; 1.3-1.8 mm

11. rhois Blackman

12(10). Body slender, 2.6 times as long as wide; sulcus extending anterior to declivital base between sutural striae; lateral convexities of declivity armed by fine, rounded granules; setae on sides of elytra very long, coarse; S California to S Nevada; Pinus; $1.6-2.0 \mathrm{~mm}$
12. pini Blackman

Body stout, 2.4 times as long as wide; sulcus not extending anterior to
declivital base; lateral convexities of declivity armed by pointed denticles ............ 13
13(12). Declivital interstriae 3 armed by small, pointed denticles; declivital sulcus deeper, narrower; antennal club larger, at least three times as wide as last funicular segment, 1.1 times as long as wide; S Arizona; Carnegia gigantea; $1.6-2.3 \mathrm{~mm}$ 13. hubbardi Schwarz

- Declivital interstriae 3 armed by a row of about three to eight long, slender teeth; declivital impression almost flat; antennal club small, not more than twice as wide as last funicular segment, 1.3 times as long as wide; S California to Baja California; Bursera; 1.6-2.1 mm

14. desertus Bright
15. Cactopinus microcornis Wood Fig. 153

Cactopinus microcornis Wood, 1969, Coleopt. Bull. 23:45 (Holotype, male; 10 km S Ihuajuapan, Oaxaca, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from mexicanus Wood by characters summarized in the above key.

Male.- Length $1.5-1.9 \mathrm{~mm}, 2.0$ times as long as wide; color black.

Frons rather narrowly concave on median half, about two-thirds of concave area above upper level of eyes, lower area halfway between epistomal margin and upper level of eyes armed by a pair of hornlike tubercles, distance between tubercles and height of each tubercle about equal to its basal width; surface subreticulate, with rather sparse fine punctures; vertex rather coarsely rugose-reticulate, vestiture rather sparse, hairlike, abundant, and coarse on epistomal margin. Antennal club circular in outline, sutures moderately bisinuate.

Pronotum 0.89 times as long as wide; widest a third of length from base, posterior two-thirds of sides very strongly arcuate, narrowly rounded in front; basal margin slightly produced behind in median area; summit on basal fourth; asperities begin on median third just behind anterior margin and extend to pointed posteromedian extremity projecting above scutellum, closely set but not high, asperate area rather abruptly subinflated on posterior half; lateral areas almost smooth, with isolated, setiferous, rounded granules of moderate size; vestiture hairlike, rather sparse, of moderate length.

Elytra 1.2 times as long as wide, 1.3 times as long as pronotum; sides almost straight and parallel on more than basal two-thirds, broadly subemarginate behind; sutural striae
feebly, others not at all impressed, punctures coarse, deep, close; interstriae narrower than striae, uniseriately granulate to base, nodules increase in height posteriorly. Declivity short, very steep, strongly sulcate; striae 1 rather strongly impressed; interstriae 1 moderately elevated, areas lateral to striae 1 ascending to broad summit on 4 , tubercles absent on 1 and 2 , of moderate size on 3 and 4 , coarse on 5 to 9 . Vestiture consisting of interstrial rows of moderately long hair on $3,5,7$, and lateral areas, setae on other interstriae minute if present.

Female.- Similar to male except frontal concavity not as deep and extending further toward epistoma, tubercles entirely absent; elytral tubercles very slightly smaller.

Distribution.- Oaxaca.
MEXICO: Oaxaca: 10 km , No. 44 , and 32 km , No. 47, S Huajuapan, 16-VI-67, 2000 m , giant cactus, S. L. Wood.

Biology.- As described for the genus. When competing for space with granulifer, this species tended to occupy the summits of the cactus ridges.

Notes.- The above treatment was based on the type series of 58 specimens.

## 2. Cactopinus mexicanus Wood

 Fig. 153Cactopinus mexicanus Wood, 1967, Great Basin Nat. 27:37 (Holotype, male; 21 km N Juchitlán, Jalisco, Mexico; Wood Coll.)
Diagnosls.- This species is distinguished from the closely allied microcomis by the much longer epistomal horns and the more deeply concave frons of the male, by the much more strongly sulcate elytral declivity, and by the smaller elytral tubercles.

Male.- Length $1.3-1.6 \mathrm{~mm}, 2.0$ times as long as wide; color black.

Frons deeply, broadly excavated from vertex to epistomal area; epistoma armed by two widely spaced hornlike spines, each spine about four times as long as its basal width, separated from one another by basal width of a spine; excavated area glabrous, a few setae on spines, epistomal brush conspicuous. Eye, antenna, and pronotum as in microcornis except posterolateral areas of pronotum more coarsely granulate.

Elytra as in microcornis except interstrial granules largely obsolete on anterior half of disc, smaller in posterior areas; lateral convexities on declivity abruptly elevated and much higher, sulcus between them deep; striae 2 usually obsolete in vicinity of lateral convexities of declivity; sutural interstriae on declivity with low, rounded granules.

Female.- Similar to male except frons flattened, transversely impressed just above epistoma, horns absent.

Distribution.- Jalisco.
MEXICO: Jalisco: 21 km N Juchitlán, 2-V11-65, 1000 m , No. 176, giant cactus, S. L. Wood.

Host.- Probably Pachycereus pectenaboriginum.

Biology.- This species infested dry, yellowing tissues immediately below the epidermis of a large, dying arm of its host. The tunnels were so crowded their pattern could not be ascertained, but evidently they were similar to related species.

Notes.- The above treatment was based on the type series of 114 specimens.

## 3. Cactopinus cactophthorus Wood

 Fig. 154Cactopinus cactophthorus Wood, 1957, Great Basin Nat. 17:105 (Holotype, male; 16 km SE Tehuitzingo, Puebla, Mexico; Snow Ent. Mus., Univ. Kansas)

Fig. 153. Cactopinus microcornis, male head and elytral declivity. (After Wood 1969:46.)

Diagnosis.- This species is distinguished from the allied niger Wood and granulifer Wood by the very different frontal excavation in the male and larger epistomal horns, and by other characters mentioned in the above key.

Male.- Length 1.2-1.4 mm, 2.3 times as long as wide; color black.

Frons very deeply excavated from vertex to epistoma, including lateral margins; excavated area almost flat to rather shallowly concave in transverse direction, very deeply concave on longitudinal axis; upper margin abrupt; surface minutely subrugose; epistomal horns fused except at tips, length about equal to length of frontal excavation (variable); tubercle at lateral margin near antennal insertion rather well developed. Antennal club rather small, 1.2 times as long as wide; sutures straight.

Pronotum 1.02 times as long as wide; widest just behind middle, sides moderately arcuate on slightly more than basal half, rather narrowly rounded in front; summit on basal fourth; asperities narrow, high, extending from base to anterior margin; lateral areas minutely granulose, devoid of granules. Vestiture of sparse hair.

Elytra 1.4 times as long as wide; sides almost straight and parallel on basal two-thirds, broadly rounded behind except lateral convexities of declivity project to give a subemarginate appearance; striae 1 feebly impressed, punctures coarse, deep; interstriae distinctly narrower than striae, minutely irregular, punctures small, uniseriate. Declivity very steep, rather broadly sulcate; strial punctures much smaller than on disc, rows except 1 not clearly discernible; interstriae 2 strongly impressed, l convex, slightly

Fig. 153 continued. Cactopinus mexicanus, male head and elytral declivity. (After Wood 1969:46.)
elevated, lateral areas strongly, rather abruptly elevated in central area, not on lower fourth; granules small, confused except on interstriae 3 . Vestiture largely confined to sides, of moderately coarse, short, interstrial hair.

Female.-Similar to male except frons moderately, transversely impressed on central half, its sides rounded, epistomal horns absent; lateral convexities on elytral declivity less strongly elevated, granules smaller.

Distribution.- Puebla.
MEXICO: Puebla: 24 km SE Acatlán, 16-V1-67, No. 41, giant cactus, S. L. Wood; Tehuitzingo, 3-VII-53, giant cactus, S. L. Wood.

Biology.- As described for mexicanus. A small piece of exceedingly dry cactus was kept to preserve an example of the tunnels of this species. It was examined six weeks later and found to contain an active colony of this species, presumably derived from unhatched eggs or previously unnoticed larvae. Three flights of beetles were preserved from this colony, emerging at about one- to two-month intervals. The piece of cactus was almost reduced to powder by the beetles before it was fumigated.

Notes. - The above treatment was based on 79 paratypes and on 19 other specimens.

## 4. Cactopinus niger Wood

Cactopinus niger Wood, 1969, Coleopt. Bull. 23:46 (Holotype, male; 32 km S Huajuapan, Oaxaca, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from cactophthorus Wood by characters summarized in the above key.

Male.-Length $1.6-1.9 \mathrm{~mm}, 2.3$ times as long as wide; color black.

Frons deeply, broadly concave from base of horns to vertex, upper margin acute; basally contiguous pair of horns arise just above epistoma, fused on their basal half, diverging distally, their total length slightly less than distance equal to longitudinal axis of frontal concavity; lateral margins armed by a pair of small tubercles just above antennal insertion; surface of concavity smooth to subreticulate, with a few minute punctures, area above concavity rugose-reticulate; vestiture of fine, short hair above horns, slightly longer on horns, much longer and somewhat reddish on epistomal margin. Antennal club rather small, oval, sutures straight.

Pronotum 1.0 times as long as wide; widest on basal third, sides moderately arcuate, distinctly constricted on anterior third, rather narrowly rounded in front; posterior margin produced behind in median area; asperate area beginning just behind anterior margin on median third, expanding laterally toward middle, then narrowed to median process at base, not inflated laterally, transition to asperate area gradual; lateral areas smooth, with isolated rounded granules, granules transcend gradually into asperities above; vestiture hairlike, longer anteriorly.

Elytra 1.26 times as long as wide, 1.34 times as long as pronotum; sides almost straight and parallel on basal two-thirds, broadly subemarginate behind; striae 1 weakly, others not impressed, punctures coarse, close, deep; interstriae smooth but undulating, punctures uniseriate, moderately large, deep, their anterior margins slightly higher, a few weak granules toward declivity. Declivity short, steep, strongly, broadly sulcate; striae 1 strongly impressed on upper twothirds; interstriae 1 slightly elevatd, lateral areas ascending to broad summit on 4, lower fourth of 2 flattened, 3-9 each bearing a uniseriate row of moderately large, high, rounded tubercles. Vestiture consisting of a few short, interstrial, hairlike setae on declivity and sides.

Female.- Similar to male except frons feebly convex with a shallow impression on median third, horns entirely absent.

Distribution.- Oaxaca.
MEXICO: Oaxaca: 32 km S Huajuapan, Oaxaca, I6-VI-67, 2000 m , No. 46, giant cactus, S. L. Wood.

Biology.- As described for the genus. The host species had a distinctive bluish color.

Note.- The above treatment was based on the type series of 82 specimens.

## 5. Cactopinus granulifer Wood

Cactopinus granulifer Wood, 1969, Coleopt. Bull. 23:48
(Holotype, male; 6 km S Huajuapan, Oaxaca, Mexico; Wood Coll.)
Diagnosis.- As indicated by the characters summarized in the above key, this species is very closely related to niger Wood.

Male.- Length $1.3-1.6 \mathrm{~mm}, 2.36$ times as long as wide; color black.

Frons deeply, broadly concave from epistomal horn to vertex, upper margin abrupt,
subacute; epistomal horns similar to but smaller than in niger, about two-thirds as long as longitudinal axis of concavity; surfaces and vestiture as in niger. Antennal club rather small, subcircular in outline; suture 1 straight, 2 feebly bisinuate.
Pronotum 1.02 times as long as wide; as in niger except asperities begin well behind anterior margin and do not extend as far laterally, granules in lateral areas smaller and less abundant, intermixed with numerous, close, fine, deep punctures; vestiture hairlike, longer anteriorly.

Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; outline essentially as in niger; striae 1 feebly, others not impressed, punctures coarse, deep, close, with interspaces between punctures uniseriately granulate, granules increasing in size posteriorly until almost as large as those of interstriae at declivital margin; interstriae narrower than striae, irregular, uniseriate granules increasing in size toward declivity. Declivity short, very steep, broadly, deeply sulcate; general sculpture as in niger except lateral convexities higher, granules higher, much more numerous (including those on striae), granules reduced on striae 1 and interstriae 1 on lower two-thirds. Vestiture consisting of uniseriate rows of erect interstrial hair of moderate length, except minute on declivity.

Female.- Similar to male except frons weakly convex, with a slight transverse impression near upper level of eyes.

Distribution.- Oaxaca.
Mexico: Oaxaca: 6 km N Totolapan, 20-VI-67, 1200 m, No. 67: 6 km , No. 44, and 32 km , No. 47 , S Huajuapan, $16-\mathrm{VI}-67,2000 \mathrm{~m}$; all from giant cactus by S . L. Wood.

Host.- Giant cactus.
Biology. - As described for the genus. When in competition for space with microcornis, this species tended to avoid the summits of ridges on the host.

Notes.- The above treatment was based on the type series of 97 specimens.

## 6. Cactopinus nasutus Wood

Cactopinus nasutus Wood, 1969. Coleopt. Bull. 23:49 (Holotype, male; 16 km S Matamoros, Puebla, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from cactophthorus Wood by the broad antennal club, which has bisinuate sutures, and
by other characters summarized in the above key.

Male.- Length 1.4-1.7 mm, 2.2 times as long as wide; color black.

Frons extensively excavated from epistomal horns to well back on vertex, reaching inner margins of eyes and exceeding width of eyes above, upper margin acute; surface of excavation smooth, shining, a feebly median elevation on lower half; horns rather large, as long as longitudinal axis of excavation, their proximal half fused, diverging slightly apically, subapical tufts of hair well developed; a pair of small tubercles located on lateral margins just above antennal insertion; vestiture confined to horns and epistomal margin. Antennal club large, circular in outline, sutures very strongly bisinuate.

Pronotum 1.02 times as long as wide; outline as in niger; asperities attain anterior margin and blend laterally with rounded granules; a few, fine, punctures evident laterally; vestiture hairlike, longer anteriorly.

Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; outline as in niger; striae 1 weakly, others not at all impressed, punctures coarse, deep, close; interstriae almost as wide as striae, shining, undulating slightly, punctures uniseriate, rather coarse, deep, close, not at all granulate. Declivity steep, broadly, rather shallowly sulcate; general sculpture as in niger, tubercles on interstriae 3-9 uniseriate, comparatively small, those on lower half of 1 and 2 obsolete. Vestiture consisting of uniseriate rows of interstrial hair; not evident in impressed area of declivity.

Female.- Similar to male. except frons weakly convex, flattened below, with a pair of low, subtuberculate, raised areas in position of male horns.

Distribution.- Puebla to Oaxaca.
MEXICO: Oaxaca: 6 km N Totolapan, 20-Vl-67, 1200 m , No. 67, giant cactus, S. L. Wood. Puebla: 16 km S Matamoros, 14-VI-67, 1700 m , No. 36, giant cactus, S. L. Wood.

Host.- Giant cactus.
Biology.- As described for the genus.
Notes.- The above treatment was based on the type series of 81 specimens.

## 7. Cactopinus carinatus Wood

Cactopinus carinatus Wood, 1969, Coleopt. Bull. 23:50 (Holotype, male; 26 km N Ixmiquilpan, Hidalgo, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from nasutus Wood by characters summarized in the above key.

Male.-Length 1.5-1.8 mm, 2.4 times as long as wide; color black.

Frons as in nasutus except excavation slightly less extensive above, and divided by a distinctly elevated, median carina; horns slightly smaller. Antennal club large, subcircular in outline, sutures very strongly bisinuate, 1 angulate. Pronotum and elytra as in nasutus except strial punctures smaller, interstrial punctures on disc minute, declivital granules of reduced size, and declivital sulcus narrower, lateral convexities more abruptly elevated.

Female.- Similar to female of nasutus except frons with a median carina on upper half, transverse impression at upper level of eyes more pronounced, and subepistomal elevations somewhat more extensive.

Distribution.- Hidalgo.
MEXICO: Hidalgo: 26 km N Ixmiquilpan, lo-VII-67, 1700 m , No. 190 , giant cactus, S. L. Wood.

Biology.- As described for the genus.
Notes. - The above treatment was based on the type series of 48 specimens.
8. Cactopinus depressus Bright

Cactopinus depressus Bright, 1967, Canadian Ent. 99:921 (Holotype, male; 46 miles or 73 km N San Luis Potisí, San Luis Potosí, Mexico; Canadian Nat. Coll., 9391); Wood, 1969, Coleopt. Bull. 23:51 (female)
Diagnosis.- This species is distinguished by the very small, shallow strial punctures, by the absence of interstrial granules, and by other characters mentioned in the key. Its relationship to other species is not close.

Male.-Length $1.3-1.5 \mathrm{~mm}, 2.6$ times as long as wide; color very dark brown to black.

Frons very deeply concave from vertex to epistoma, but somewhat less extensively than in most other species; fused epistomal horns slightly shorter than longitudinal axis of excavation; surface minutely granulate. Antennal club small, about 1.4 times as long as wide; two very obscure sutures indicated by rows of setae.

Pronotum 1.0 times as long as wide; widest just behind middle, sides weakly arcuate, subparallel on basal two-thirds, very broadly rounded in front, almost straight on median half of anterior margin; summit on basal fourth, narrow, high asperities on triangular elevated area, a few extending to anterior fourth; lateral areas almost smooth. Vestiture confined to marginal areas, of coarse hair, a few exceedingly long.

Elytra 1.6 times as long as wide; sides straight and parallel on more than basal twothirds, obtusely subangulate behind, slightly produced; striae not impressed, punctures very small, shallow; interstriae about three times as wide as striae, smooth, shining, except entire surface usually covered by a thin, dull incrustation, punctures fine, shallow. Declivity moderately steep, deeply, rather narrowly sulcate, sulcus extending almost to middle of elytra; surface essentially as on disc; lateral convexities on upper half rather abrupt, moderately high. Vestiture largely confined to sides, of sparse, coarse, rather long, hairlike setae.

Female.- Similar to male except frons irregularly convex, finely granulate; declivital sulcus very shallow.

Distribution.-San Luis Potosí to Hidalgo.

MEXICO: Hidalgo: 26 km N Ixmiquilpan, 10-VII-67, 1900 m , No. 189, Yuced, S. L. Wood. San Luis Potosí: 73 km N San Luis Potosí, 2-IX-58, Yucca, E. Mockford.

Host.- Yucca sp.
Biology.- This species infested the yellow, dying leaves of a very large, branching, living Yucca tree. The entrance tunnels were mostly on the lower surfaces. The transverse adult galleries were essentially as described for the genus; straight, longitudinal larval mines were made between fibers of the leaf and were rather long.

Notes.- The above treatment was based on the holotype and 121 other specimens.

## 9. Cactopinus spinatus Wood Fig. 154

Cactopinus spinatus Wood, 1957, Great Basin Nat. 17:106 (Holotype, male; 2 km SE Cameron, Oaxaca, Mexico: Snow Ent. Mus., Univ. Kansas)
Diagnosis.- This species has large declivital spines comparable to those of desertus Bright, but the pronotal asperities are much
more widely distributed, the pronotal summit is not at all conical, the declivital sulcus is much deeper and wider, and the declivity lateral to interstriae 3 is armed by several coarse tubercles.

Male.-Length $1.4-1.7 \mathrm{~mm}, 2.5$ times as long as wide; color black.

Frontal concavity essentially as in cactophthorus except surface rather coarsely punctured; fused epistomal horns longer than longitudinal axis of concavity; lateral angles above antennal insertion coarsely bituberculate, a smaller tubercle on epistomal margin near median line; vestiture of fine, short setae on acute upper margin of concavity, conspicuous on horns and epistomal margin.

Pronotum 1.0 times as long as wide; widest just behind middle, sides moderately arcuate, converging very slightly on basal two-thirds, broadly rounded in front; summit at base, not conical or projecting, asperate area somewhat elevated, rather sharply defined on a rather definite, narrow triangle from base to anterior margin; asperities narrow, high, less numerous on anterior fourth; lateral areas shining, with fine punctures and granules.

Fig. 154. Cactopinus and Pseudothysanoes: C. cactophthorus, 1, male, 4, antenna, 5, scape, 6, protibia; C. spinatus, 2, male, 3, male head, 7, parental gallery with egg niches; P. multispinatus, 8, lateral aspect of male elytra. (After Wood 1957:I08.)

Vestiture of fine and coarse, short and very long, moderately abundant hair.

Elytra 1.6 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, posterior margin straight on median two-thirds; striae 1 moderately impressed toward declivity, punctures rather coarse, deep; interstriae about half as wide as striae, minutely granulate, somewhat convex, odd-numbered interstriae regularly granulate, granules slender, moderately high, other interstriae irregularly granulate. Declivity steep, rather broadly, deeply excavated; punctures in excavated area small, confused except on striae 1 ; interstriae 1 strongly depressed, rather weakly convex, with a row of very fine granules; excavated area rather narrow above, broad below, lateral elevations very high, median margins of their summits armed by a row of four to seven coarse, slender teeth, lateral margins of summits armed by similar smaller teeth; lateral areas with several smaller denticles, presumably on interstriae 3 to 9 . Vestiture of strial and interstrial hair, short and fine to long and very coarse; rather abundant.

Female.- Similar to male except frons very shallowly impressed, all tubercles represented but smaller, those in position of horns widely separated and each about as high as wide; declivital spines slightly larger.

Distribution.- Jalisco to Oaxaca.
MEXICO: Jalisco: 1 km N Atenquique, 21-VI-65, 1000 m , No. 112 . Bursera. S. L. Wood. Oaxaca: 2 km SE Cameron, 7 -Vll- $53,800 \mathrm{~m}$, twigs of laige tree; 57 km SE Cameron, 22-Vl-67, No. 83, Bursera; 6 km N Totolapan, 20-VI-67, 1100 m , No. 62, Bursera; all by S. L. Wood.

Hosts.- Bursera spp., etc.
Biology. - Specimens were taken from small dying branches on living trees of three species of Bursera and of one other tree genus. The galleries evidently were similar to those described for the genus. Resins from the tree and beetle activity from this and Dendroterus species greatly complicated observation.

Notes.- The above treatment was based on 14 paratypes and on 79 other specimens.

## 10. Cactopinus koebelei Blackman

Cactopinus koebelei Blackman, 1938, Proc. Ent. Soc. Washington 40:156 (Holotype, male, Argus Mts., Inyo, California; U.S. Nat. Mus., 52796)

Diagnosis.- This species is distinguished from thois Blackman by the very shallowly impressed declivital sulcus, and by the absence of granules on declivital interstriae 1-3 (fine granules on upper half in some specimens).

Male.- Length 1.3-1.5 mm, 2.5 times as long as wide; color black.

Frons presumably as in rhois (concealed in specimens at hand); lateral areas unarmed by tubercles; horns straight, fused, less than half as long as pronotum. Antennal club very small, 1.5 times as long as wide, sutures straight.

Pronotum 1.0 times as long as wide (projecting summit excluded); widest at middle, sides weakly arcuate and subparallel on basal two-thirds, broadly rounded in front; summit projecting rather strongly behind base above scutellum, asperate area abruptly, strongly elevated on narrow triangular area to anterior fourth, anterior fourth neither elevated nor asperate; lateral areas finely, closely, shallowly, irregularly punctured. Vestiture abraded in specimens at hand.

Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on more than basal two-thirds, narrowly rounded behind; striae impressed, punctures coarse, moderately deep; interstriae half as wide as striae, slightly irregular, punctures fine, obscure, uniseriate. Declivity steep, rather broadly convex with a slight sulcus; striae 1 impressed on upper half, lateral convexities on upper half moderately high, rounded; strial punctures slightly smaller than on declivity; interstriae $l$ and 3 with irregular, obscure indications of very fine granules. Vestiture largely confined to lateral areas, of sparse short and sparse coarse, long hair.

Female.-Similar to male except frons convex above eyes, a transverse impression on lower half, horns represented by a pair of widely spaced, large, blunt tubercles about as high as wide.

Distribution.- Baja California to SW Utah.

USA: California: Argus Mts., V-9I, A. Koebele; Lock wood Canyon, 13-V-13, Pimus monophylla, A. D. Hopkins: Mt. Hawkins, 13-V1-40, P. lambertiana, C. R. Bruck; Mt. Pinos, 30-VIII-41, P. monophylla, C. R. Brack; Pith Creek, 13-V-13, P. monophylla, A. D. Hopkins: Valyermo, 1-I, I-V-37, P. monophylla, A. T.
Mc.Clay. Utah: Deep Creek Mts. near Calleo, Juab Co., 24-V11-57, P. monophylla, D. E. Bright. MEXICO: Baja California: Laguna Hanson, 27-VIII-58, E. L. Sleeper.

Host.-Pinus monophylla and $P$. lambertiana.

Biology.- Presumably this species breeds in small twigs of pinyon pine.

Notes. - The above treatment was based on the holotype and on 93 other specimens.

## 11. Cactopinus rhois Blackman Fig. 96

Cactopimus rhois Blackman, 1938, Proc. Ent. Soc. Washington 40:154 (Holotype, male: Ventura Co., California; U.S. Nat. Mus. 52795)
Diagnosis.- This species is distinguished from the allied koebelei Blackman by the more strongly sulcate elytral declivity, and by the presence of moderately coarse granules on declivital interstriae 1 to 3 .

Male.- Length 1.3-1.8 mm, 2.5 times as long as wide; color black.

Frons strongly excavated from epistoma to vertex, upper margin obtusely angulate; very shallowly concave at middle on transverse line; surface shining, rather coarsely, closely, shallowly punctured; horns equal to slightly less than half length of pronotum; lateral epistomal tubercles absent. Antennal club as in koebelei.

Pronotum as in koebelei.
Elytra 1.5 times as long as wide; outline about as in rhois; striae 1 moderately impressed, punctures rather coarse, moderately deep; interstriae shining, slightly more than half as wide as striae, punctures very fine, evidently supplemented by rather numerous, confused, impressed points almost as large as punctures. Declivity steep, rather broadly convex, with a moderately impressed sulcus; striae 1 strongly impressed; interstriae 1 depressed, convex, area lateral to striae 1 ascending rather abruptly to rounded summit; all interstriae with small, high, rather closely set granules. Vestiture of moderately abundant, fine, short and long, coarse hair.

Female.- Frons as in koebelei except frontal tubercles smaller; otherwise as in male.

Distribution.-S California.
USA: California: Montrose, 16-XII-34, Rhus trilobata, and 10-XII-33, Rhus otata, C. R. Bruck; Henniger Flats, Mt. Wilson, 2I-Vl-40, R. ovata, C. R. Bruck; Coyote Creek in Ventura Co., 20-VI-40, R. trilobata, C. R. Bruck.

Hosts.- Rhus diversilobata, R. trilobata.
Brology.- As described for the genus.
Notes.- The above treatment was based on the holotype and on 266 other specimens.

## 12. Cactopinus pini Blackman

Cactopinus pini Blackman. 1938, Proc. Ent. Soc. Wachington 40:153 (Holotype, male; Griffen, Kern. California: U.S. Nat. Mus., 52794)
Diagnosis.- This species is distinguished from the closely allied rhois Blackman by the less strongly impressed male frons, by the longer male horns, by the steeper, more strongly sulcate elytral declivity, and by the absence of elytral granules particularly on the declivity.

Male.- Length $1.6-2.0 \mathrm{~mm}, 2.6$ times as long as wide; color black.

Frons as in rhois except flattened or weakly convex on a transverse line, surface more finely punctured; epistomal horns straight, longer, about half length of pronotum. Pronotum as in rhois.

Elytra 1.5 times as long as wide; sides almost straight and parallel on basal two-thirds, very broadly rounded behind; dise as in rhois except evidently impressed interstrial points reduced or absent (obscured by incrustation). Declivity steep, very strongly sulcate; sutural interstriae very strongly impressed above, impression expanding to interstriae 3 below; lateral areas abruptly, very strongly, broadly elevated; granules not evident. Vestiture of coarse, very long, rather sparse, interstrial hair, and more abundant, finer, short hair.

Female.- Similar to male except frons not excavated, rather narrowly flattened, horns absent.

Distribution.-S California and Nevada.
USA: California: Ventura Co., 13-XI-05 (or 17-XI-06?), Hopk. US 2775, Jeffrey pine, A. D. Hopkins; Frazier Mt., 6-IX-40, Pinus monophylla, C. R. Bruck; Mt. Pinos, 30-VII1-41, P. monophylla, C. R. Bruck. Nevada: Reno, Melrose Highway, 5-IV-74, P. jeffreyii, M. M. Furniss.

Hosts - Pinus jeffreyii and P. monophylla.
Biology.- Specimens were taken from shaded out branches of the host.

Notes. - The above treatment was based on the holotype and on 73 other specimens.

## 13. Cactopinus hubbardi Schwarz

Cactopinus hubbardi Schwarz, 1899, Pssche 8(Suppl. I):I1 (Lectotype, male; Tucson, Arizona; U.S.

Nat. Mus., present designation); Blackman, 1938, Proc. Ent. Soc. Washington 40:152 (redescription)
Diagnosis. - This species probably is more closely allied to rhois than to other known species, but it is distinguished by the stouter body form, by the steeper elytral declivity, by the smaller declivital granules, which are absent on interstriae 1 and 2 , by the stouter pronotal asperities, and by the longer male epistomal horns.

Male.- Length 1.6-2.3 mm, 2.2-2.4 times as long as wide; color very dark brown to black.

Frons as in pini, epistomal horns often much longer.

Pronotum 0.96 times as long as wide (protruding summit omitted); essentially as in rhois except asperities stouter and obsolete on anterior fourth.

Elytra 1.4 times as long as wide; sides almost straight and parallel on basal two-thirds, rather broadly subemarginate behind; striae 1 moderately impressed, strial punctures coarse, deep; interstriae slightly narrower than striae, weakly convex, almost smooth, punctures fine, uniseriate. Declivity very steep, rather deeply sulcate; sutural striae deeply impressed, impression wider below; lateral areas abruptly, rather strongly elevated; interstriae 2 armed by granules only at base, 3 and 4 tuberculate to their apices, lateral areas with occasional smaller granules. Vestiture of moderately long, coarse, rather abundant hair.

Female.-Similar to male except frons convex above, very shallowly concave on narrow area below, epistomal horns absent.

Distribution.-S Arizona.
USA: Arizona: Tucson, 31-XII-1896. Cereus giganteus, H. G. Hubbard and E. A. Schwarz: Sabino Canyon, Pima Co., 9-VIII-62. Carnegiea gigantea, S. L. Wood: Santa Catalina Mits., 17-IN-64, saguaro.

Host.-Carnegiea gigantea.
Biology.- This species differs in habits from all other giant-cactus-inhabiting species. It breeds only in scar tissue formed in the living host on the inner walls of deep cavities, such as those made by woodpeckers. The tunnels are very shallow in the scar tissue.

Notes.- The above treatment was based on the lectotype, about 240 paratypes, and on 14 other specimens. The male in the type collection at the U.S. National Museum has
been regarded as the type, but it has never been officially designated. It is here designated as the lectotype of this species.

## 14. Cactopinus desertus Bright

Fig. 96
Cactopinus desertus Bright, 1967, Canadian Ent. 99:923 (Holotype, male; 7 miles or 11 km S Ocotillo Wells, Anza-Borrego Desert Park, San Diego Co., California; California Acad. Sci.)
Diagnosis. - The declivital armature of this species superficially resembles that of spinatus Wood, but the pronotal characters are as in hubbardi and its allies. The distinguishing characters were summarized in the above key.

Male.- Length $1.6-2.1 \mathrm{~mm}, 2.4-2.5$ times as long as wide; color black.

Frons as in rhois; epistomal horns straight, usually more than half as long as pronotum. Pronotum as in rhois, anterior fourth devoid of asperities.

Elytra 1.6 times as long as wide; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind, outline interrupted by projecting declivital spines; striae 1 moderately impressed, strial punctures coarse, deep; interstriae about half as
wide as striae, somewhat convex, punctures fine. Declivity steep, rather broadly, deeply sulcate; striae 1 clearly indicated, 2 and 3 obsolete; lateral convexities high, armed by a row of six to nine large, spinelike teeth beginning at base on interstriae 2 but diverging to what probably is interstriae 3 (judged from tubercles on other species), alternate teeth often smaller. Vestiture of sparse short and very long, coarse hair.

Female.- Similar to male except frons as in female hubbardi, epistomal brush especially well developed.

Distribution.-S California to Baja California.

USA: California: 7 miles or 11 km S Ocotillo Wells, Anza-Borrego Desert State Park, 1I-111-65, Bursera microphylla, C. W. O’Brien. MEXICO: Baja California: 50 km N La Paz, 27-III-74, Bursera, M. M. Furniss; 11 km SW Mission San Borja, 31-Ill-73, Bursera, J. Doyen; Santa Rosalia, 29-III-74, Bursera, M. M. Furniss.

Host.- Bursera microphylla.
Biology.- As described for the genus. Specimens were taken from small branches, limbs, and bole; evidently several generations were produced in the same tree.

Notes.- The above treatment was based on 2 male and 2 female paratypes and on 37 other specimens.

Tribe IPINI

lpint Bedel, 1858, Amm. Soc. Ent. France, hors serie 6:386 (Type-genus: Ips DeGeer, 1775)

Anatomical features.- The frons is usually sexually dimorphic, the eye is sinuate to shallowly emarginate, the antennal funicle is 5 -segmented, the club is either obliquely truncate or the sutures on the posterior face are strongly displaced toward the apex, the pronotum is declivous and asperate on the anterior half, its lateral margins are rounded, the coxae are contiguous, and the declivity is usually strongly impressed or excavated, with the lateral margins armed by spinose denticles.

Biological features.- All are polygamous and phloeophagous. Eggs are deposited in niches. Larval mines are individual and rarely cross one another. Symbiotic fungi apparently are associated with them, but not in a mycetophagous sense. The northern genera are restricted to coniferous hosts, Acanthotomicus occurs in broadleaf trees.

Taxonomy.- Because only a minor fraction of the species groups found in Eurasia are represented in American Pityogenes and Orthotomicus, it is presumed that these genera originated in Eurasia and reached North America rather recently. The reverse situation is found in Pityokteines and Ips, where a North American origin is postulated; the ancestral stock from which both were derived presumably reached North America from Eurasia in an earlier migration. Acanthotomicus occurs in tropical America, Africa, and the Indo-Australian area; species groups common to both South America and Africa suggest a faunal exchange well after the basic generic features were fixed. The lpini are a compact group, closely allied to the Dryocoetini, in which the generic limits may be obscure. The separation of Ips and Orthotomicus is particularly difficult and may not be justified.

## Genus Pityogenes Bedel

Pityogenes Bedel, 1888, Ann. Soc. Ent. France, hors ser. 6:397 (Type-species: Dermestes chalcographus Linnaeus, original designation)
Eggersia Lebedev, 1926, Ent. Blätt. 29:121 (Type-species: not designated): Schedl, 1962, Centralbl. Forstw. 79:132. Synonymy
Pityoceragenes Balachowsky, 1949, Faune de France 50:244 (Type-species: Bostrichus bidentatus Herbst, original designation); Schedl, 1958. Tijdschr. Ent. 101:145. Synonymy
Diagnosis.- Within the tribe Ipini this genus is distinguished by the very short, obtuse intercoxal piece on the prosternum, and by the large spines on the elytral declivity. The females of all American species, except meridianus Blackman, have a large fossal excavation on the frons; this character does not occur in most European or Asian species.

Description.- Length 1.8--3.7 mm, 2.5-2.7 times as long as wide; light brown to almost black.

Frons sexually dimorphic, male convex, female with a large central fossa (except meridianus); vestiture hairlike, sparse, inconspicuous. Eye elongate-oval, weakly sinuate on anterior margin; finely granulate. Antennal scape elongate; funicle 5 -segmented; club oval, two sutures on anterior face, 1 reaching basal half, posterior face with one suture well below apex. Pronotum slightly longer than wide; anterior slope asperate, punctured on posterior areas; anterior margin serrate. Scutellum well-developed, flat. Elytra with small, widely spaced strial and interstrial punctures in somewhat obscure rows; declivity gradual to steep, sulcate, armed by two or three pairs of denticles, those in male much larger. Vestiture hairlike, rather inconspicuous.

Distribution.- North America, Europe, and Asia where native pine forests grow; 19
species are known; 7 occur in North America.

Brology.- The American species infest trees of the genus Pinus. They breed primarily in slash and in cut or fallen limbs and branches, although they are not uncommon in the bole or in standing, dying trees. All species are polygamous. The male forms the entrance tunnel and nuptial chamber; the females cut long egg galleries in the cambium
region that radiate out from the nuptial chamber. Eggs are deposited in individual niches made by the female for that purpose. Larval mines radiate away from the egg gallery in a more or less irregular pattern; they are visible on the surface of peeled bark throughout their length. Pupation occurs in the cambium region, and young adults emerge from individual exit holes.

Key to the Species of Pityogenes

1. Male elytral declivity armed by three pairs of coarse denticles; female declivity rather gradual, armed by three pairs of denticles of about equal size and equally spaced; female frontal fossa large, undivided; in 5-needle pines

- Male elytral declivity armed by two pairs of teeth, upper pair long, slender, hooked; female declivity very steep, armed by three pairs of denticles, upper pair much smaller and much closer to second pair; female fossa divided by a median septum, except undivided in carimulatus and absent in meridianus 3

2(1). Pronotal disc more deeply, closely punctured; female frontal fossa large, extending well above upper level of eves; male elytral declivity more strongly impressed, denticles distinctly larger; British Columbia and California to Arizona and Colorado; Pinus monticola, P. flexilis; 1.8-2.5 mm

1. fossifrons (LeConte)

- Pronotal disc less deeply, very sparsely punctured; female frontal fossa much smaller, ending well below upper level of eyes; male elytral declivity shallowly impressed, denticles distinctly smaller; Minnesota and Newfoundland to Tennessee and North Carolina; Pinus strobus; 1.8-2.1 mm .......... 2. hopkinsi Swaine
3(1). Punctures on elytral declivity coarse, rather deep; female frons convex, devoid of fossal excavation
- Punctures on elytral declivity fine to obsolete; female frons with a conspicuous fossal excavation

4(3). Smaller species; upper male declivital spines less strongly hooked; discal interstriae with punctures more confused; female elytral declivity less strongly convex, sulcus wider; North Carolina to Mississippi; Pinus echinata, P. taeda; $2.5-3.0 \mathrm{~mm}$
3. meridianus Blackman

- Larger species; upper male declivital spines more strongly hooked; discal interstriae more regularly punctured; female elytral declivity more strongly convex, sulcus narrower; Mexico; Pinus hartwegii; 3.2-3.4 mm

4. mexicanus Wood

5(3). Larger; lower fourth (variable) of posterolateral margin of male elytral declivity carinate, carina ending in lower tooth; female frontal fossa very large, extending well above upper level of eyes, undivided; British Columbia and South Dakota to California and Chihuahua; Pinus; 2.3-3.7 mm

- Smaller; posterolateral margin of male declivity rounded; female frons with fossa smaller, not extending above upper level of eyes, divided by a median partition

6(5). Female frontal fossa usually smaller, not as deep, often poorly formed; elytral surface and surface of vertex tending to be smoother; elytral vestiture averaging very slightly longer; E Alberta and Quebec to North Carolina; Pinus; $1.9-2.5 \mathrm{~mm}$
6. plagiatus (LeConte)

- Female frontal fossa larger, deeper; elytral surface and vertex tending to be wrinkled to subrugose; elytral vestiture averaging slightly shorter; British Columbia, Alberta, and South Dakota to California and Colorado; Pinus contorta; $1.9-2.9 \mathrm{~mm}$

7. knechteli Swaine

## 1. Pityogenes fossifrons (LeConte)

Pityophthorus fossifrons LeConte, 1876, Proc. Amer. Philos. Soc. 15:353 (Lectotype, female; V'ancouver Island, British Columbia; Mus. Comp. Zool., 1028, present designation)
Diagnosis.- This species is closely related to chalcographus (Linnaeus), of Europe and Asia, but it has the elytral declivity less strongly impressed, with the lateral denticles slightly smaller, and it has the female frons slightly narrower, with the frontal spongy area and fossa distinctly smaller.

Male.- Length $1.8-2.5 \mathrm{~mm}, 2.6$ times as long as wide; color very dark brown, almost black.

Frons broadly convex; surface shining, punctures rather small, close, moderately deep, some very feebly granulate; vestiture of fine, sparse, inconspicuous hair. Eye 2.0 times as long as wide; antennal club with suture 1 straight.

Pronotum 1.1 times as long as wide; widest at base, sides weakly arcuate, converging toward narrowly rounded anterior margin; anterior margin armed by eight subcontiguous teeth; summit at middle; anterior slope asperate; posterior area smooth, shining, surface marked by many minute points, punctures rather coarse, deep, moderately close, interstriae about equal to diameter of a puncture; median line impunctate, distinctly elevated. Vestiture restricted to marginal areas; sparse.

Elytra 1.6 times as long as wide, 1.3 times as long as pronotum; sides almost straight and parallel on basal three-fourths, rather broadly rounded behind; striae not impressed, obscure, punctures very small, not deep; interstriae about four to six times as wide as striae, somewhat irregularly marked by shallow lines, minute points, etc., punctures equal in size and appearance to those of striae, widely spaced. Declivity moderately steep, broadly
sulcate, lateral margins armed by three pairs of coarse, equally spaced, pointed teeth; strial and interstrial punctures in impressed area obsolete, part of surface near suture subreticulate. Vestiture hairlike, sparse.

Female.- Similar to male except central third of frons with a very deep, cone-shaped cavity extending well above upper level of eyes, area between cavity and epistomal margin spongy and finely pubescent; elytral declivity steeper, less strongly, less broadly impressed, lateral denticles much smaller but of equal size to one another.

Distribution.- British Columbia and California to Arizona and Colorado.

CANADA: British Columbia: Adam's Lake, Cowitchan, Rossland, Sugar Lake, Trinity Valley. USA: Arizona: Hannagan Camp in Greenlee Co. California: Big Pines, Blancos Corral, Callahan in Siskyou Co., Glen Alpine, Grassy Lake in Lassen Co., Inyo N.F., Onion Valley in Inyo Co., White MIt. in Mono Co., Yosemite. Colorado: Long's Peak, Manitou Mt., Pingree Park. Idaho: Coeur d'Alene, Franklin Basin Road in Franklin Co., Kellogg, Kootenai, Krassel, Sand Point. Montana: Sheridan. Nevada: Lee. Oregon: Santiam Pass. Utah: Brighton, Logan Canyon, Logan Dry Canyon. Washington: Easton, Metaline Falls. Wyoming: Saratoga.

Hosts.-Pinus albicaulis, P. balfouriana, P. flexilis, monticola, P. strobiformis, rarely in other hosts.

Biology.- This locally abundant species breeds mostly in slash and broken limbs and branches. In Utah the egg galleries are almost exclusively transverse; the only two gallery systems observed in Oregon were of the typical unmodified star shape. Larval mines in Utah are parallel to the grain of the wood.

Notes.- The above treatment was based on the lectotype and on 211 other specimens. The one female syntype remaining in the LeConte collection is here designated as the lectotype of Pityophthorus fossifrons LeConte, as indicated above.

## 2. Pityogenes hopkinsi Swaine

 Fig. 155Pityogenes hopkinsi Swaine, 1915, New York St. Coll. For., Syracuse, Tech. Pub. 2:8 (Lectotype, female; Ste. Amne de Bellevie, Quebec; Canadian Nat. Coll., 9294. designated by Bright, 1967, Canadian Ent. 99:677)
Diagnosis.- This species is distinguished from fossifrons (LeConte) by the smaller average size, by the less deeply, more sparsely punctured pronotal disc, by the smaller female frontal fossa, and by the less strongly impressed male elytral declivity.

Male.- Length 1.8-2.1 mm, 2.5 times as long as wide; color brown.

Frons and pronotum as in fossifrons except pronotal punctures less numerous, interstriae averaging about twice as wide as diameter of a puncture. Elytra as in fossifrons except declivity less strongly, more narrowly impressed, lateral denticles slightly smaller.

Female.- Similar to male except differing as female fossifrons differs from male and frontal fossa smaller, ending well below upper level of eyes, spongy area smaller; declivital sulcus not as deep, narrower.

Distribution.- Minnesota and Newfoundland to Tennessee and North Carolina.

Fig. 155. Pityogenes hopkinsi: 1, male; 2, female. (After Blackman 1915:pl. I.)

CANADA: Newfoundland, New Brunswick, Nova Scotia, Ontario, Quelec. USA: Connecticut, Illinois, Indiana, Maine, Massachusetts, Michigan, Minnesota, New Hampshire, New Jersey, New York, North Carolina, Ohio, Pennsylvania, Tennessee, Virginia, West Virginia, Wisconsin.

Hosts. - Pinus strobus.
Biology.- Essentially as in fossifrons (Blackman 1915).

Notes.- The above treatment was based on 553 specimens; the lectotype was also examined.

## 3. Pityogenes meridianus Blackman Fig. 156

Pityogenes meridianus Blackman, 1921, Mississippi Agrie. Expt. Sta. Tech. Bull. 10:15 (Lectotype, male; Meridian, Mississippi; U.S. Nat. Mus., present designation)
Diagnosis.- This unique species is distinguished from all other American representatives of the genus by the coarsely punctured elytral declivity, by the absence of a fossal excavation on the female frons, and by the distribution.

Male.- Length 2.5-3.0 mm, 2.6 times as long as wide; color dark reddish brown to almost black.

Frons as in knechteli Swaine except more strongly convex, punctures very close, deep, rather coarse, tubercles slightly more abundant. Pronotum as in knechteli except punctures on disc larger and without evident granules on their margins.

Elytra about as in knechteli except discal punctures distinctly larger. Declivity similar except punctures in excavated area much coarser and deeper; posterolateral margin of declivity with two small teeth, margin between these denticles and upper spine with about five small granules; upper spines and vestiture as in knechteli.

Female.- Similar to male except frontal punctures and granules much smaller; not excavated as in the other American species; declivity as in female knechteli except more broadly impressed, punctures coarse and deep.

Distribution. - North Carolina to Mississippi.

USA: Mississippi: A\&M, 3-NI-19, Mi. 10, M. W Blackman (also Meridian, Hattiesburg). North Carolina: Durham, 6-X-39, Pinus taeda, J. A. Beal.

Brology.- This rare species evidently lives in shaded-out branches of living, standing trees.

Notes. - The above treatment was based on the syntypic type series of 11 specimens and on one other specimen. I here designate Blackman's male type, on which his description was based, as the lectotype of this species.

## 4. Pityogenes mexicanus Wood

Pityogenes mexicanus Wood, 1950, Great Basin Nat. 40:356 (Holotype, female; Parque Nacional Zoquiapan. Mexico, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from meridianus Blackman by the much larger size, by the shorter, more strongly hooked upper spines on the male elytral declivity, by the more regularly punctured discal interstriae, and by the much more strongly convex female elytral declivity. The female frons of this species and meridianus differs from all other American Pityogenes in lacking a deeply excavated central area.

Male.- Length 3.2-3.4 mm, 2.6 times as long as wide; color very dark brown.

Frons broadly granulate, a few fine punctures interspersed; vestiture of fine, long, moderately abundant hair.

Pronotum essentially as in meridianus except minute, impressed points much more numerous.

Elytra essentially as in meridianus except interstrial punctures regular, about equal in size to those of striae; upper declivital spines slightly shorter, more strongly hooked, series of tubercles on lower fourth of lateral margin much lower and rounded except lowest one larger and pointed (male meridianus not at hand; comparison based on Blackman's drawing).

Female.- Similar to male except median line on upper half of frons shallowly concave; epistomal area on median third slightly protuberant, granulate, and ornamented by moderately abundant, fine, short hair; frontal tubercles smaller; declivity shallowly, narrowly sulcate (more shallowly impressed than any other American Pityogenes), declivity with stouter, more abundant vestiture than in meridianus.

Distribution.- Mexico.
MEXICO: Mexico: Parque Nacional Zoquiapan, VIIl79. Pinus hartuegii branch, T. H. Atkinson.

Notes.- The above treatment was based on the type series of four specimens.

## 5. Pityogenes carinulatus (LeConte) <br> Fig. 158

Cryphalus carinulatus LeConte, 1574 Trans. Amer. Ent. Soc. 5:70 Lectotype, female: California: Mus. Comp. Zool., 1005: present designation)
Xylcborus humatus LeConte. 1874. Trans. Amer. Ent. Soc. 5:72 (Lectotype, male; Mojave desert, California: Mus. Comp. Zool., 1004, present designation); LeConte, 187s, Proc. Amer. Philor. Soc. 17:624. Synomymy
Diagnosis. - This species is distinguished from other American representatives of the genus by the large size, by the very large, undivided female frontal fossa, and by the carinate ventrolateral margin of the male elytral declivity.

Male.- Length 2.3-3.7 mm, 2.5 times as long as wide; color dark brown.

Fig. 156. Pityogenes meridianus: 7, female; 8-9, male; 10, female? (After Blackman 1921:13.)

Frons broadly convex, with a slight central impression; surface shining, closely, rather coarsely granulate-punctate; vestiture of fine, long hair of moderate abundance. Eye 2.3 times as long as wide. Antennal club with sutures 1 and 2 bisinuate, slightly procurved.

Pronotum 1.1 times as long as wide; sides almost straight and parallel on slightly more than basal half, rather abruptly, arcuately narrowed to distinct constriction just before rather narrowly rounded anterior margin; anterior margin armed by about 10 small teeth; summit at middle; anterior slope coarsely asperate; posterior area smooth, shining, punctures rather small, moderately close, deep, those near summit somewhat granulate; median line impunctate, subacutely elevated. Vestiture of sparse hair.

Elytra 1.4 times as long as wide, 1.3 times as long as pronotum; sides almost straight and parallel on basal two-thirds, then arcuately narrowed to lower denticles, broadly, shallowly emarginate on median third; striae not impressed, punctures small, widely spaced, rows not always regular; interstriae smooth, shining, six or more times as wide as striae, punctures as those of striae but rows more irregular. Declivity rather steep, broadly, rather shallowly excavated; upper margin armed on interstriae 2 by a pair of long, slender, hooked, hornlike spines; lower denticles of moderate size, pointed, on ventrolateral margin on interstriae 2 , ventrolateral margin strongly, acutely elevated from lower tooth about one-fourth of distance toward upper spine, remaining margin rounded; declivital face smooth and shining, punctures sparse except on striae 1 , minute.

Female.-Similar to male except frons deeply excavated on median area from just above epistoma to vertex, epistomal area minutely, densely punctured; declivity steeper, more narrowly, very shallowly sulcate, lateral margins rounded, armed by three small teeth, distance from denticle 1 to 2 half as great as from 2 to 3,1 much smaller.

Distribution.- S British Columbia and W South Dakota to California and Chihuahua.

CANADA: British Columbia: Aspen Grove, Midday Valley, Princeton, Shingle Creek, Vernon. USA: Arizona: Flagstaff, Kaibab N.F., Prescott, Sunset Crater. Williams. California: Alpine Co., Blanco's Corral, Cannel Meadows, Chester, Cisco, El Dorado Co., Faunskin, Fresno Co., Grass Lake, Guernevville, Humboldt Co.,

Hat Creek, Huntington Lake, Kern Co., Lake Tahoe, McCloud, Myers, Norval Flats, Plumas N.F., San Bernardino Co., Shasta Co., Ventura, Weaverville. Colorado: Colorado N.F., Durango, Estes Park, Poudre Canyon. Idaho: Athol, Centerville, Coeur d'Alene, Moscow. Montana: Columbia Falls, Pine Grove. Nebraska: Nanzel. Norden, Valentine. Nevada: Kyle Canyon in Clark Co., Lake Tahoe. New Mexieo: Capitan, Las Vegas, Meek. Oregon: Grants Pass, Hood River, La Grande, Sisters. South Dakota: Black Hills, Custer, Elmore, Hill City, Lead, Spearfish. Utah: Kamas, Long Valley Junction, Panguitch Lake, Pin Hollow in Fishlake N.F., Sanford Canyon in Dixie N.F. Washington: Buckeye, Spokane. Wyoming: Buffalo, Lusk. MEXICO: Chihuahua: San Juanito, 15-111-74, Pinus, M. M. Furniss.

Hosts.- Pinus ieffreyi, P. ponderosa; less common in other species of Pinus, rare in other conifers.

Biology.- This species is very common in slash. The habits are essentially as described for the genus.

Notes.- The first syntype in the LeConte series of carinulatus, a female, is here designated as the lectotype of Cryphalus carinulatus LeConte. The first syntype in the LeConte series of Xyleborus hamatus, a male, is here designated as the lectotype of hamatus LeConte. The above treatment was based on the LeConte series of 10 specimens and on 341 other specimens.

## 6. Pityogenes plagiatus (LeConte)

Nyleborus plagiatus LeConte. 1868, Trans. Amer. Ent. Soc. 2:161 (Lectotype, male; Maryland; Mus. Comp. Zool., 1003, present designation)
Pityogenes lecontei Swaine, 1915, New York St. Coll. For., Syracuse, Tech. Pub. 2:10 (Holotype, male; Marquette, Michigan; Mus. Comp. Zool.); Wood, 1957. Canadian Ent. 89:400. Synonymy

Diagnosis.- This species has the female frontal fossa divided by a median partition; the ventrolateral margin of the male elytral declivity is rounded. It is almost indistinguishable from knechteli Swaine, as indicated in the above key and in the diagnosis of that species.

Male.- Length 1.9-2.5 mm, 2.5 times as long as wide; color brown to very dark brown.

Frons broadly convex; surface shining, coarsely granulate below upper level of eyes, becoming punctate above; vestiture of fine, long, moderately abundant hair; epistomal brush conspicuous. Eye and antenna as in fossifrons (LeConte). Pronotum as in carinulatus (LeConte).

Elytra as in carinulatus except ventrolateral margin of declivity rounded, not at all carinate near lower tooth.

Female.- Similar to male except median third of frons below upper level of eyes excavated, excavation divided by a median partition, epistomal area somewhat spongy and minutely, densely pubescent; declivity as in female carinulatus.

Distribution.- Alberta and Quebec to North Carolina.

CANADA: Alberta: Smith. Manitoba: Marchand, Molson. Ontario: Constance Bay, Geraldton, Larchwood, Low Bush, Marson, Ottawa, Petawawa Res., Red Lake, Wavell. Quebec: Ft. Coulogne, Maniwaki. USA: District of Columbia: Brightwood, Washington. Maryland: Beltsville. Michigan: Camp Raco in Chippewa Co., Marquette. Minnesota: Cass Lake, Cloquet, Lake Itasca, Lake of the Woods. North Carolina: Durham. Pennsylvania: Kansas Valley in Perry Co., Mt. Alto, York. Virginia: Arlington, Chatham, Garrisonville, Onville, Rixey. West Virginia: Hampshire Co.. Kanawha Station, Ridgeville, Romney, Roosevelt, W'ood Co.

Hosts.-Pinus banksiana, P. echinata, $P$. resinosa, p. virginiana.

Biology.- The habits are essentially as described for the genus.

Notes. - The above treatment was based on the lectotype of plagiatus, on the holotype of lecontei, and on 236 other specimens. From the syntypic series of LeConte I here designate the first specimen, a male, from Maryland, labeled "Type No. 1003," as the lectotype of plagiatus. Swaine described the seventh specimen in this series as the holotype of lecontei.

This species is almost indistinguishable from knechteli and may hybridize with that species; see the taxonomic notes under that name.

## 7. Pityogenes knechteli Swaine Figs. 157-158

Pityogenes kuechteli Swaine, 1918, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(2):106 (Holotype, female; Beau Vent Lake, Jasper Park, Alberta; Canadian Nat. Coll., 9295)
Diagnosis.- This species is distinguished, with difficulty, from plagiatus LeConte by minute differences in the sculpture and vestiture, and by the female frontal fossa as indicated in the above key. It is entirely possible they are only geographical races of one another.

Male.- Length 1.9-2.9 mm, 2.6 times as long as wide; color brown to almost black.

Virtually identical to plagiatus except female with frontal fossa slightly larger, much deeper than plagiatus; surface of elytral disc tending to be wrinkled and, toward declivity, subrugose; elytral vestiture averaging slightly shorter.

Female.-See above.
Distribution.- British Columbia, Alberta, and W South Dakota to California and Colorado.

CANADA: Alberta: Banff Springs, Cypress Hills, Exshaw, Jasper Park, Sinith. British Columbia: Chetwynd, Creighton Valley, Hope Mt., Kooteney Valley, Lorma, Merritt, Peachland, Stanley, Trinity Valley. Saskatchewan: Cypress Hills. USA: California: Big Pines Park, Clover Valley in Lassen N.F., El Dorado Co., Fresno Co., Lone Pine, Madera Co., Mariposa Co., Mono Co., Myers, Rowell Meadow in Tulare Co., San Bernardino Co.. Shasta Co., Tulare Co., Tuolumne Co., Yosemite. Colorado: Camp Hale, Colorado N.F., Estes Park, Fraser, Gould, Grand Lake, Leadville, Pingree N.P., Rocky Mt. N.P., Troga Pass. Idaho: Cascade, Krassel, Smith; Ferry, Soda Springs, Tuttle. Montana: Big Horn N.F.. Columbia Falls, Clacier N.P., Mullan, Polaris, Ramshorn Canyon near Sheridan, Rocky Boy Indian Res. in Lake Co., Sula. Wisdom. Oregon: Chemult, North Powdery Peaks, Ochoco N.F., Warner Mts. in Lake Co. Utah: Elk Park in Ashley N.F., Hoop Lake in Wasatch N.F., Kamas, Logan Canyon, Mirror Lake in Summit Co. Wyoming: Keystone, Minview, Sheridan. Teton N.F.. Wood's Landing in Albany Co.

Hosts.- Pinus contorta.
Biology.- Very abundant in slash and fallen trees. The habits are essentially as described for the genus.

Notes. - The above treatment was based on the holotype and on 357 other specimens.

Fig. 157. Pityogenes knechteli, galleries: A, nuptial chamber; B, egg gallery; C, egg niche. (After Reid 1955:318.)

This is either an allopatric sibling species or a poorly differentiated subspecies of plagiatus. One series from Peace River, Alberta, in the zone of host hybridization, is intermediate between knechteli and plagiatus. If additional material from that region supports that indication of intergradation, then they must be treated as subspecies, as was done by Bright (1976:142).

## Genus Pityokteines Fuchs

Pityokteines Fuchs, 1911, Morphologische Studien uber Borkenkafer: I. Die Gattungen Ips DeGeer und Pityogenes Bedel, p. 33 (Type-species: Ips curvidens Germar, subsequent designation by Hopkins, 1914, Proc. U.S. Nat. Mus. 48:127)
Orthotomides Wood, 1951, J. Ent. Soc. Kansas 24:32 (Type-species: Orthotomicus lasiocarpi Swaine, original designation); Wood, 1975, Great Basin Nat. 35:21. Synonymy
Diagnosis.- In this genus the antennal club is obliquely truncate, as in Orthotomicus. From Orthotomicus it is distinguished by the narrowly excavated elytral declivity, with the lateral margins rounded, the lower margin narrowly, poorly developed, about half as long as distance between third pair of spines; by the absence of a spiracle on abdominal tergum 7; and by the long, abundant, conspicuous vestiture on the head and anterior parts of the pronotum in the female.

Description. - Length $1.6-2.9 \mathrm{~mm}$, 2.5-2.8 times as long as wide; color brown to very dark brown.

Frons rather strongly convex and sparsely pubescent (males) to weakly convex and densely pubescent (females, except moderately in ornatus, sparse in lasiocarpi). Eye very shallowly emarginate, rather small. Antennal scape elongate; funicle 5 -segmented; club obliquely truncate, two sutures evident on anterior face, none, one, or two on
posterior face. Pronotum slightly longer than wide; summit near middle, anterior area declivous and asperate, posterior area punctured. Scutellum rather large, flat. Elytra weakly to moderately striate; declivity sulcate to rather deeply excavated, impression deeper in males; lateral margins armed by three pairs of denticles, denticles larger in males; apex of declivital excavation subacutely, transversely elevated near suture, transverse length of this elevation equal to about half distance between lowest (third) denticles. Prosternal intercoxal piece acuminate.

Distribution.- N North America and N Eurasia; nine species are known, six of them occur in North America.

Biology.- These polygamous species construct radiate or star-shaped parental galleries in the phloem of the larger limbs or bole of cut, fallen, or dying trees. Their tunnels may or may not show on the surface of peeled bark. The larval mines are rather short, somewhat irregular, and they may or may not be in contact with the cambium. Reports as to their aggressiveness vary from a primary enemy of balsam fir (sparsus) to a secondary invader following the attack of Ips in ponderosa pine (ornatus).

Notes.- This genus is not sharply separated from Orthotomicus when only females are compared. However, when males are compared and all species are considered on a worldwide basis, two distinct cluster of species, without intermediates, are apparent. I prefer to recognize both as distinct genera. Schedl (1964) went to the opposite extreme and grouped Ips, Orthotomicus, Acanthotomicus, and Pityokteines into one large genus. In my opinion the grouping of such diverse species groups is not justified at the present time.

Key to the Species of Pityokteines

1. Larger; pronotum 1.25 times as long as wide; base of second declivital tooth in male enlarged, making this tooth appear much larger than 1 or 3; female frons strongly convex, rather coarsely granulate-punctate, vestiture rather sparse, about as in male; British Columbia and South Dakota to California and Colorado; Pinus ponderosa, etc.; $2.1-2.9 \mathrm{~mm}$ 1. ornatus (Swaine)

- Smaller; pronotum 1.05-1.20 times as long as wide; second declivital tooth in male little if any larger than third, its base moderately inflated or not; female frons very weakly convex, minutely, densely punctured, usually devoid of granules, pubescence dense and very long except greatly reduced in lasiocarpi; Abies
2(1). Elytral declivity of male weakly to moderately impressed, with lateral denticles small; in female weakly impressed, with denticles minute to obsolete; body 2.8-3.0 times as long as wide
- Elytral declivity of male strongly impressed, with lateral denticles rather coarse, in female moderately impressed, with denticles moderately large (as large or larger than male minutus); body 2.5-2.6 times as long as wide
3(2). Female with dorsal half of frons and anterior fourth of pronotum ornamented by abundant, very long setae; posterior face of antennal club with suture 1 at apical margin; elytral punctures modertely coarse; British Columbia and Alberta to Arizona and New Mexico; Abies lasiocarpa; 1.7-2.3 mm

2. minutus (Swaine)

- Female with setae on dorsal half of frons and anterior fourth of pronotum rather sparse, short; posterior face of antennal club with suture 1 subapical, 2 at apical margin; elytral punctures fine
4(3). Lower third of female frons with a dense brush of long hair; anterior margin of pronotum more narrowly rounded; declivital sulcus more deeply, more narrowly impressed; Washington; Abies amabilis; $1.7-2.1 \mathrm{~mm}$

3. mystacinus Wood

- Female frons with sparse, short pubescence; anterior margin of pronotum broadly rounded; declivital sulcus more broadly, more shallowly impressed; British Columbia and Alberta to Utah; Abies, Pseudotsuga; 1.6-1.9 mm

4. lasiocarpi (Swaine)

5(2). Strial punctures averaging slightly larger, deeper, closer; surface near lateral margins of pronotum subreticulate; British Columbia and N Idaho to California; Abies concolor, A. magnifica, A. procera, 1.9-2.6 mm .. 5. elegans Swaine

- Strial punctures averaging slightly smaller, not as deep and more widely spaced within a row; pronotal surface near lateral margins smooth; shining; E Alberta and Newfoundland to Wisconsin and West Virginia; Abies balsamea; $1.6-2.1 \mathrm{~mm}$ 6. sparsus (LeConte)

1. Pityoktcines ornatus (Swaine) Fig. 158
Orthotomicus ornatus Swaine, 1916, Canadian Ent. 48:185 (Lectotype, female; Williams, Arizona: Canadian Nat. Coll., 9298, designated by Bright, 1967, Canadian Ent. 99:676)
Pityokteines ornatus: Wood, 1966, Great Basin Nat. 26:27
Diagnosis.- This species is distinguished from other American species in the genus by the larger average size, by the basally enlarged, submammiform spine 2 on the male elytral declivity, by the less abundant vestiture on the female frons, by the more
strongly convex, granulate female frons, and by the host.

Male.- Length $2.1-2.9 \mathrm{~mm}, 3.0$ times as long as wide; color very dark reddish brown.

Frons convex, a weak, transverse impression on lower half; surface shining, rather coarsely granulate-punctate from epistoma to vertex; vestiture of fine, rather abundant, moderately long hair.

Pronotum 1.25 times as long as wide; sides almost straight and parallel on basal twothirds, anterolateral angles rather abrupt, rather broadly rounded in front; summit at

Fig. 15s. Lpini spp, heads and elytral declivities: a. Pityogenes carimulatus. female; b, Pityogenes knechteli, female: c, Pityoktcines ornatus. female, d. same, male; e, Orthotomicus caclatus, female. (After Bright 1976:146.)
middle; strongly declivous and rather coarsely asperate on anterior slope; posterior area smooth, shining, with obscure, minute points, punctures rather coarse, deep, moderately close. Vestiture of moderately abundant, fine, rather long hair.

Elytra 1.7 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal three-fourths, broadly rounded behind, with lower declivital spines interrupting outline; striae 1 moderately, others feebly impressed, punctures moderately large, deep, very close; interstriae as wide as striae, smooth, shining, with minute, obscure points, punctures uniseriate, moderately coarse, deep, widely spaced. Declivity abrupt, very steep, rather broadly, deeply excavated; interstriae 1 weakly elevated, finely, closely punctured, striae 1 deeply, coarsely punctured, lateral areas gradually, strongly elevated, with large, deep, confused punctures; a small denticle on interstriae 2 at base of declivity, spine 2 large, on an inflated, elevated, submammiform base, in line with interstriae 3 , on upper third of declivity; elevated, rounded, lateral margin continued to spine 3 on lower third, spine 3 rather large, conical, slightly smaller than 2 ; subapical margin a rather weakly, subacutely elevated costa at apex of interstriae I , two subtuberculate calluses on margin between costa and spine 3. Vestiture of moderately abundant, long strial and interstrial hair, longer at declivity.

Female.- Similar to male except lateral margins of declivity much less strongly elevated, spines 2 and 3 little if any larger than 1 ; vestiture slightly shorter.

Distribution.-S British Columbia and W South Dakota to California, Arizona, and Colorado.
CANADA: British Columbia: Merritt, Midday Valley, Summerland. USA: Arizona: Flagstaff, Kaibab N.F., Prescott, Walker, Williams. California: Bass Lake, Bear Lake, Burney, Carrville, Charlton, Chiquita Basin, Crystal Lake, Fallen Leaf Lake, Faunskin, Hackamore, Hat Creek, Idyllwild, Little Yosemite, Mather, Madrone, McCloud, Modoc N.F., Moffit Creek near Ft. Jones, Mt. Laguna, Northfork, Pinehurst, Placerville. San Jacinto Mts., Sugar Pine, Swayne, Tehachapi Mt. in Kern Co., Trinity Co., Tulare Co., Yosemite. Colorado: Bailey, Cascade, Colorado N.F., Colorado Springs, Fort Collins, Gumnison, Las Animas, Larkspur, San Isabel N.F.. Uncompahgre N.F. Idaho: Centerville. Montana: Bighorn N.F., Pine Grove, Riggins. New Mexico: Albuquerque.

Bandelier Mts., Capitan, Cloudcroft, Ft. Wingate, Lincoln N.F., Los Alamos, Sandia Mits. Oregon: Ashland, Ft. Rock, Keno, Klamath N.F., Klamath Falls, Ochoco N.F. South Dakota: Black Hills, Elmore, Hill City. Utah: Beaver, Bryce N.P., Elk Park in Ashley N.F., Pin Hollow in Fishlake N.F.. Panguitch Lake, Long Hollow in Dixie N.F., Sanford Canyon in Dixie N.F., Parowan.

Hosts.- Pinus ponderosa, less common in P. attenuata, P. contorta, P. edulis, P. jeffreyi, and Picea pungens.

Brology.- This species attacks the bole of dying, standing, cut, or fallen trees usually in association with Ips species well after the Ips are established. It infests the islands of phloem that remain. The gallery system may be entirely or partly in the phloem, or it may contact the cambium and be visible on peeled bark. Because the tunnels may be entirely concealed in peeled bark, it commonly is overlooked.

Notes.- The above treatment was based on 234 specimens, several of which I had compared to Swaine's type series.

## 2. Pityokteines minutus (Swaine)

Dryocoetes mimutus Swaine, 1912, Canadian Ent. 44:352 (Lectotype, female; Canadian Nat. Coll., 9370, designated by Bright, 1967, Canadian Ent. 99:674)
Pityokteines minutus: Swaine, 1918, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(2):124
Pityokteines jasperi Swaine, 1916, Canadian Ent. 48:181 (Lectotype, female; Jasper Park, Alberta; Canadian Nat. Coll., 9296, designated by Bright, 1967. Canadian Ent. 99:677): Wood, 1957, Canadian Ent. 89:401. Synonymy
Diagnosis.- This species is distinguished from others in the genus by the more poorly developed declivital spines, by the slender body form, and by the host.

Male.- Length $1.7-2.3 \mathrm{~mm}, 2.8$ times as long as wide; color dark brown.

Frons and pronotum about as in ornatus (Swaine) except pronotum 1.20 t4mes as long as wide.

Elytra as in female ornatus except striae 1 weakly, others not impressed, punctures smaller, more widely spaced, lateral margin of declivity on interstriae 6 and 7 with small, subtuberculate calluses, and denticles more sharply pointed.

Female.-Similar to male except frons very weakly, broadly convex, minutely, densely punctured over entire area, granules absent, densely covered by very long hair,
anterior margin of pronotum ornamented by similar hair; elytral declivity somewhat similar but shallowly, narrowly excavated, lateral areas rounded, not elevated, denticles reduced to small granules, sometimes entirely absent; elytral vestiture slightly shorter.

Distribution.- British Columbia and Alberta to Arizona and New Mexico.

CANADA: Alberta: Jasper Park, Tidler. British Columbia: Hope Trail ( 46 mile camp), Lorna, McGillivary. USA: Arizona: Grand Canyon N.P., Kaibab N.F., Pinaleno Mts. Colorado: Gould, Rabbit Ears Pass, Rico, Ridgeway, Wolf Creek Pass. Montana: Cohmbia Falls, Glacier N.P. New Mexico: Grants, Sandia Mts. Oregon: Crescent, Grant Co., Odel Lake. Utah: Hobble Creek in Utah Co., Horse Valley in Dixie N.F., Kamas, Logan Canyon, Logan Dry Canyon, Manti, Soapstone Creek in Wasatch N.F. Washington: Metaline Falls. Wyoming: Saratoga.

Hosts. - Abies lasiocarpa.
Biology.-As described for the genus.
Notes. - The above treatment was based on 228 specimens, several of which were compared directly to the type series of minutus and jasperi.

## 3. Pityokteines mystacinus Wood

Pityokteines mystacinus Wood, 1975, Great Basin Nat. 35:29 (Holotype, female; Mount Rainier National Park, Washington; Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from minutus (Swaine) by the smaller size, by the very different ornamentation of hair on the female frons, by the finer pronotal and elytral punctures, and by other characters. It is probably much more closely related to lasiocarpi (Swaine).

Female.- Length $1.7-2.1 \mathrm{~mm}, 3.0$ times as long as wide; color brown.

Frons similar to lasiocarpi except more broadly convex, surface not as smooth, somewhat dull, punctures averaging smaller and, on lower third, becoming almost obsolete; vestiture on lower third abundant, rather long, epistomal brush very broad, rather dense; setae on upper half of frontal area sparse, short. Antennal club almost as in lasiocarpi.

Pronotum as in lasiocarpi except anterior margin more narrowly rounded; vestiture uniformly short as in lasiocarpi. Elytra as in lasiocarpi except punctures on disc slightly larger, very slightly more confused on basal half, and declivital striae 1 more strongly impressed, with punctures on striae 1 slightly
larger, subapical transverse elevation at apex of sulcus more distinct (but still rather obscure); position, number, and size of tubercles as in lasiocarpi. Vestiture similar in abundance, but very slightly longer than in lasiocarpi.

Male.-Similar to female except upper half of frons more strongly convex, vestiture on lower third greatly reduced in abundance and length; elytral declivity with sulcus slightly deeper (about as in male lasiocarpi) but narrower.

Distribution.- Washington.
USA: Washington: Mt. Rainier N.P., 21-VIII-62, silver fir, D. E. Bright.

Host.- Abies amabilis.
Notes.- The above treatment was based on the type series of 5 specimens.

## 4. Pityokteines lasiocarpi (Swaine)

Fig. 160
Orthotomicus lasiocarpi Swaine, 1916, Canadian Ent. 48:183 (Lectotype, female; Rogers Pass, British Columbia; Canadian Nat. Coll., 9300, subsequent designation by Bright, 1967, Canadian Ent. 99:676)
Orthotomides lasiocarpi: Wood, 1951, J. Ent. Soc. Kansas 24:32.
Pityokteines lasiocarpi: Wood, 1975, Great Basin Nat. 35:2I
Diagnosis.- This species is rather easily distinguished from other Pityokteines species by characters of the antennal club, by the vestiture of the female, and by the much smaller declivital spines in the male.

Male.- Length $1.6-1.9 \mathrm{~mm}, 2.8$ times as long as wide; color dark brown.

Frons broadly convex; surface smooth, shining, with rather fine, close, deep punctures below, becoming larger and rather sparse toward vertex; vestiture of fine, rather sparse, short hair.

Pronotum 1.2 times as long as wide; widest behind middle, sides feebly arcuate, subparallel on posterior two-thirds, broadly rounded in front; summit very slightly in front of middle; anterior slope rather strongly declivous, moderately, closely asperate; posterior area smooth, shining, deeply, rather closely punctured. Vestiture of fine, inconspicuous hair.

Elytra 1.8 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal three-fourths, broadly
rounded behind; striae 1 feebly, others not impressed, punctures small, spaced within a row by about twice diameter of a puncture; interstriae three to four times as wide as striae, smooth, shining, punctures fine, uniseriate, spacing about equal to those of striae. Declivity rather steep, shallowly impressed; sutural interstriae rather weakly elevated, with a row of minute subgranulate punctures, shallowly impressed from position of striae 1 , gradually ascending to position of striae 3, surface shining, sparse, minute punctures confused, no indication of rows; all margins rounded, armed by three pairs of small, pointed denticles. Vestiture of rows of short, erect strial hair, and rows of distinctly longer, fine, interstrial hair.

Female.- Similar to male except elytral declivity less strongly, more narrowly impressed, lateral denticles minute.

Distribution. British Columbia and Alberta to Utah.

CANADA: Alberta: Banff, Blairmore, Edmonton. British Columbia: Kootenay Pass, Rogers Pass. U'SA: Idaho: Coeur d'Alene, Collens, Franklin Basin Road in Franklin Co. Montana: Glacier N. P. Oregon: Gold Lake in Willamette N.F. Utah: Brighton, Kamas, La Sal Mts., Logan Canyon, Logan Dry Canyon, Mt. Neloo. Washington: Mt. Rainier.

Hosts.- Abies amabilis, A. lasiocarpa, Picea engelmannii, Pseudotsuga menziesii.

Brology. - This polygamous species breeds in the bole and large limbs of cut, fallen, or dying trees. The parental tunnels are in the cambium region and feebly scar the surface of the wood. They are of the radiate or starshaped type. Larval mines are relatively short, and show on the phloem surface of peeled bark. It is not an aggressive species and rarely becomes abundant.

Notes. - The above treatment was based on Swaine's type series and on 265 other specimens.

## 5. Pityokteines elegans Swaine Fig. 160

Pityokteines elegans Swaine, 1916, Camadian Ent. 48:182 (Lectotype, female; Hood River, Oregon; Canadian Nat. Coll., 9297, designated by Bright, 1967, Canadian Ent. 99:677)
Diagnosis.- This species is distinguished from ornatus (Swaine) by the sexually dimorphic frons, in the male virtually devoid of granules, by the more widely spaced strial
punctures, by the smaller base of declivital spine 2, with well developed marginal tubercles between spines 2 and 3, and by the host.

Male- Length 1.9-2.6 mm, 2.6 times as long as wide; color dark brown.

Frons as in ornatus except almost entirely devoid of granules. Pronotum 1.13 times as long as wide; essentially as in ornatus except punctures immediately behind summit subgranulate to granulate; surface near lateral margins subreticulate.

Elytra 1.6 times as long as wide, 1.4 times as long as pronotum; as in ornatus except striae 1 weakly, others not impressed, punctures more widely spaced; declivital spine 2 with base only slightly inflated; lateral margin of declivity with rounded granules on interstriae 5 and 6 between spines 1 and 2; vestiture shorter, less abundant.

Female.-Similar to male except frons feebly concave, densely, minutely punctured from epistoma to vertex, surface on lower half minutely subgranulate; frons covered by abundant, long, fine hair, similar hair on anterior margin of pronotum; elytral declivity as in female ornatus.

Distribution.- British Columbia and N Idaho to California.

CANADA: British Columbia: Genoa Bay at Duncan. Qualicum. U'SA: California: El Dorado Co., Grassy Lake, Humboldt Co., Lake Tahoe, Lassen N.F., Lassen N.P., Madera Cu., Mariposa Co., Modoc Co., Mt. Raymond Trail, Placer Co., Plumas Co., Sequoia N.F., Norval Flats in Lassen Co., Shasta Co.. Trinity Co., Tulare Co., Tuolumne Co., Yosemite. Idaho: Deception Creek, Coeur d'Alene, Potlatch. Oregon: Ashland, Corvallis, Hood River, Pinehurst. Washington: Metaline Falls, Spokane.

Hosts.- Abies concolor, A. magnifica, less common in other hosts, except apparently restricted to Pseudotsuga menziesii in northern Idaho.

Biology.- Evidently more common in dying, standing trees up to about 25 cm in diameter. Habits apparently are as described for the genus.

Notes.- The above treatment was based on 132 specimens, several of which were compared to Swaine's type series by me.

## 6. Pityokteines sparsus (LeConte)

Xyleborus sparsus LeConte, 1868, Trans. Amer. Ent. Soc. 2:160 (Holotype, female: Point Keweenaw

#### Abstract

on Lake Superior, Michigan; Mus. Comp. Zool., 1002)

Pityokteines sparsus: Swaine, 1918, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(2):123 Tomicus balsamcus LeConte, 1878, Proc. Amer. Philos. Soc. 17:625 (Lectotype, male; Central New York; Mus. Comp. Zool., present designation); Swaine, 1918, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(2):123. Synomymy Diagnosis.- This species is distinguished, with difficulty, from elegans Swaine by the slightly smaller, more widely spaced strial punctures, by the smooth, shining, nonreticulate lateral areas of the pronotum, and by the distribution.

Male.- Length $1.6-2.1 \mathrm{~mm}, 2.5$ times as long as wide; color dark brown.

Evidently identical to elegans except as noted in above diagnosis.

Female.- Differing from female elegans as male and female of that species differ from one another.

Distribution.- Alberta and Newfoundland to Wisconsin and West Virginia.

CANADA: Alberta: Lesser Slave Lake. Manitoba: Whiteshell Prov. Park. New Brunswick: Acadia Station, Bathurst, Fredericton, Hillsboro, McGraw Brook, Plaster Rock, Riley Brook. Newfoundland: Comerbrook, Pasadena. Nova Scotia: Kejimukıyik, Kemptown. Ontario: Algonquin N.P., Barrie, Bovs, Calandar, Caramat, Gogama, Lanark, Matatchewan, Pass Lake, South March, Whitney. Quebec: Gaspé Co., Hudson, Kazabazua, Laniel, Montreal, Ste. Anne de Bellevue, Stoke. Saskatchewan: Prince Albert N.P. USA: Maine: Brunswick, Camp Caribou, Guilford, Monmouth. Massachusetts: Fitchburg. Michigan: Charlevoix, Grand Island, Harbor Spring, Ingleside, Mackinaw, Marquette, Point Keweenaw, Seney. Minnesota: Atkin, Ely Lake, Itaska Park, St. Louis Co. New Hampshire: Dartmouth. Gorham, Waterville, Went Loc. New York: Axton, Cranberry Lake, Elka Park, Saranac Inn. Pennsylvania: Tamarack. West Virginia: Kanawha Station. Wisconsin: Cedar Island, Clintonville.

Host.- Abies balsamea.
Biology.- As in elegans.
Notes.- The above treatment was based on the holotype of sparsus, on the type series of balsameus, and on 613 other specimens. Because a type has not been selected, I here designate the first male syntype in the LeConte series as lectotype of balsameus LeConte.

## Genus Orthotomicus Ferrari

Onthotomicus Ferrari, 1867, Die Forst- und Baumsuchtschädlichen Borkenkäfer, p. 44 (Typespecies: Bostrichus Laricis Fabricius, subsequent
designation by Hopkins, 1914, Proc. U.S. Nat. Mus. 48:126)
Orthotomicus Ferrari, 1869, Berliner Ent. Zeitschr. 12:256 (correlation of lapsus calami)
Ncotomicus Fuchs, 1911, Morphologische Studien uber Borkenkäfer, 1. Die gattungen Ips DeGeer und Pityogenes Bedel, p. 33 (Type-species: Bostrichus laricis Fabricius, subsequent designation by Hopkins, 1914, Proc. U.S. Nat. Mus. 48:125); Swaine, 1918, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. I4(2):I21. Synonymy
Diagnosis.- This genus is intermediate between Pityokteines Fuchs and Ips DeGeer. It shares with Pityokteines the obliquely truncate antennal club, the more abrupt, sexually dimorphic elytral declivity, with a more poorly developed apical margin. It differs from Pityokteines in having the apical margin of the elytral declivity transversely longer than the distance between the third pair of spines, with the lateral margin more strongly, more continuously elevated, and in having the frons sexually dimorphic. It differs from Ips by the structure of the antennal club, by the more striking sexually dimorphic elytral declivity, and by the third (lowest) pair of declivital spines being distinctly mesad of the lateral margin.

Description.- Length $2.4-3.3 \mathrm{~mm}, \quad 2.5$ times as long as wide; color very dark reddish brown.

Frons convex, granulate-punctate in both sexes; vestiture sparse, inconspicuous. Eye elongate-oval, shallowly emarginate. Antennal scape elongate; funicle 5 -segmented; club obliquely truncate, two recurved sutures indicated on anterior face. Pronotum slightly longer than wide; summit indefinite, near middle; anterior area strongly declivous and asperate, posterior area punctate. Scutellum rather large, almost flat. Elytra striate; declivity abrupt, broadly excavated, lateral margins elevated, dentate, apical margin broadly, acutely elevated, forming a continuous costa as long transversely as width of entire excavated area, last (lowest) denticle placed mesad of lateral margin; declivity moderately sexually dimorphic. Tibiae as in Ips.

Distribution.- Coniferous forests of northern North America, Europe and Asia; about a dozen species are known; one occurs in North America.

Biology.- The species are polygamous and phloeophagous. They construct modified
radiate parental gallery systems in the cambium of coniferous hosts. They attack the bole or large limbs of dying, standing, cut, or fallen trees. They are of secondary ecological importance.

Notes.- This genus has been of doubtful validity since it was first proposed. It occupies an intermediate position between Pityokteines, from which it is doubtfully distinct, and Ips, with which it intergrades somewhat. It is recognized here because these three groups are about equally distinct from one another and, in my opinion, it is not in the interest of either taxonomy or forestry to group Pityokteines and Ips in the same genus. If they are not grouped, the only alternative appears to be to give equal status to Orthotomicus. The reduction of one or all these groups to subgeneric status only relegates the problem to a different level and solves nothing. Although most of the published discussion on this problem has involved the relationship of Orthotomicus and Ips, it is my opinion that Orthotomicus genetically and structurally is much more closely allied to Pityokteines.

## Orthotomicus caelatus (Eichhoff) Fig. 158, 160

Tomicus caclatus Eichhoff, 1868, Berliner Ent. Zeitschr. 11:402 (Syntypes; Pennsylvania, Carolina; presumably lost in Hamburg Mus.)
Tomicus decretus Eichhoff, 1868, Berliner Ent. Zeitschr. 11:402 (Lectotype. female; New Orleans, Louisiana; Brussels Mus., present designation); LeConte, 1868. Trans. Amer. Ent. Soc. 2:177. Synonymy
Xyleborus vicinus LeConte, 1874, Trans. Amer. Ent. Soc. 5:72 (Holotype, female; British Columbia; Mus. Comp. Zool., 985); LeConte, 1876, Proc. Amer. Philos. Soc. 15:360 and Wood, 1973, Great Basin Nat. 33:179. Synonymy
Xyleborus punctipennis LeConte, 1878, Proc. Amer. Philos. Soc. 17:624 (Holotype, female; Marquette, Michigan; Mus. Comp. Zool., 1293); Wood, 1973. Great Basin Nat. 33:179. Synonymy
Diagnosis.- This is the only American species of this genus.

Male.- Length 2.4-3.3 mm, 2.5 times as long as wide; color very dark reddish brown.

Frons broadly convex, a slight transverse elevation near epistoma; surface granulatepunctate, at least part of surface above eyes usually reticulate.

Pronotum 1.16 times as long as wide; sides almost straight and parallel on more than
basal half, rather broadly rounded in front; summit indefinite, slightly in front of middle; anterior slope rather coarsely asperate; posterior area shining, often subreticulate laterally, rather coarsely, deeply punctured, those near summit granulate to subasperate. Vestiture hairlike, inconspicuous.

Elytra 1.5 times as long as wide, 1.3 times as long as pronotum; sides almost straight and parallel on basal three-fourths, subtruncate behind with third pair of denticles interrupting outline; striae 1 distinctly, others feebly impressed, punctures moderately coarse, deep, close; interstriae as wide as striae, smooth, shining, punctures uniseriate, rather widely spaced. Declivity abrupt, very steep, broadly excavated; face of declivity deeply, broadly excavated, smooth, shining, punctures on striae 1 in an indistinct row, rather coarse, shallow, not clearly formed, punctures in lateral areas similar, confused; lateral margins rather strongly elevated from interstriae 2 at base to sutural apex; spine 1 at base on interstriae 2 moderately large, acutely pointed; spine 2 basally separate from 1, in line with interstriae 3 , its base enlarged and united with a prominence in line with interstriae 4 , spine 2 rather large, acutely pointed; margin at interstriae 5 and 6 armed by separate rounded nodules, nodule at 7 poorly formed; spine 3 at level of a point between interstriae 6 and 7 , set well mesad of lateral margin, as large as spine 1 ; subapical margin formed by a subacutely elevated undulating costa from suture to a point between nodule of interstriae 7 and spine 3. Vestiture of rows of coarse interstrial hair, supplemented near base of declivity by shorter, strial hair.

Female.- Similar to male except declivital excavation not as deep, lateral margins not as high, declivital spines distinctly smaller.

Distribution.- Alaska and Nova Scotia to California and Florida.

ALASKA: Numerous localities. CANADA: Alberta, British Columbia, Manitoba, New Brunswick. Newfoundland, Northwest Territories, Nova Scotia, Ontario, Prince Edward lsland, Saskatchewan, Yukon. USA: Alabama, Arizona, Arkansas, California, Colorado, Connecticut. District of Columbia, Florida, Georgia, Idaho. Illinois, Indiana, lowa, Kansas, Louisiana, Maine, Maryland, Massachusetts, Michigan, Minnesota, Mississippi. Montana, Nebraska, Nevada, New Hampshire, New Jersey, New York, North Carolina, North Dakota, Ohio,

Oregon, Pennsylvania, South Dakota, Texas, Utah, Vermont, Virginia, Washington, West Virginia, Wisconsin, Wyoming.

Hosts.- Probably any species of Pinus, Picea, or Larix within its range.

Biology.- This common species attacks stumps, boles, limbs, and branches of dying trees, slash, etc. It is more common in the lower bole in thick bark. It is of secondary importance and usually accompanies the attack of more aggressive species. The habits are as described for the genus; egg galleries are short.

Notes. - The above treatment was based on the holotypes of vicinus and punctipennis, on Eichhoff specimens in the U.S. National Museum, possibly syntypes, of caclatus, on 3 syntypes of decretus, and on 1,209 other specimens. The first female syntype in the Chapuis series in the Brussels Museum is here designated as the lectotype for decretus Eichhoff.

## Genus ACANTHOTOMICUS Blandford

Acanthotomicus Blandford, 1894, Trans. Ent. Soc. London 1894:89 (Type-species: Acanthotomicus spinosus Blandford, monobasic)
Mimips Eggers, 1932, Rev. Zool. Bot. Afr. 22:33 (Typespecies: Ips pilosus Eggers, original designation); Wood, 1972, Great Basin Nat. 32:191. Synonymy
Diagnosis.- As in Ips DeGeer, this genus has the antemnal club strongly flattened, the lateral margin of the elytral declivity acutely to subacutely elevated, with all denticles on its summit, and the acutely elevated, transverse, subapical lower margin of the declivity broad. From Ips it is distinguished by the very strongly procurved sutures of the antennal club, by the large, coarsely faceted eyes, by the much smaller average size, and by the hosts.

Description.- Length $1.6-2.7 \mathrm{~mm}$, 2.5-2.6 times as long as wide; color yellowish
brown to very dark reddish brown; vestiture hairlike.

Frons in American species dimorphic, convex or partly impressed in males, more broadly flattened to impressed and pubescent in females. Eye very large, coarsely faceted; shallowly emarginate. Antennal scape elongate; funicle 5 -segmented; club moderately subcircular, large, strongly flattened, sutures (when visible) very strongly procurved. Pronotum slightly longer than wide; summit near middle; anterior slope moderately, closely asperate, rather strongly declivous, anterior margin armed or not; posterior area punctate. Scutellum rather large, flat. Elytra striate; declivity rather steep, broadly excavated, lateral margins elevated, dentate, subapical margin rather strongly elevated, broad, usually more strongly sculptured in males.

Distribution. - Tropical areas of Central and South America, Africa, and the Indo-Malayan area to Australia; more than 30 species are known, of which 10 occur in Central and South America, 3 of them from Central America.

Biology.- These phloeophagous, predominantly polygamous species infest limbs and branches of cut or fallen trees. The parental galleries are of the radiate type with short egg galleries. Larval mines are in the phloem and may or may not show on peeled bark. Up to 11 females were associated with one male (bidens Wood), although the average number for that species was about 5 ; ocularis (Wood) apparently is monogamous.

Notes. - Judging from recent additions to this genus and its discovery in tropical America, many more species remain to be described and much information on habits and behavior of named species must be gathered before a meaningful classification can be devised.

## Key to the Species of Acanthotomicus

1. Elytral declivity armed on upper two-thirds by at least three pairs of marginal denticles, ventrolateral margins encompassing an arc of less than one-third of a circle

- Elytral declivity armed on upper third by one or two pairs of marginal denticles, combined ventrolateral margins encompassing an arc of more than half of a circle

2(1). Smaller; male frons weakly impressed on lower half; anterior margin of pronotum finely serrate; pronotal dise partly reticulate; declivital setae on sutural interstriae stont, blunt; basal area of spine 2 on elytral declivity weakly developed; Veracruz and Jamaica to Venezuela; Spondias mombin; $1.6-2.0 \mathrm{~mm}$.......

1. mimicus (Schedl)

- Larger; male frons very strongly impressed on lower half; anterior margin of pronotum devoid of denticles; pronotal disc smooth, shining; declivital setae on sutural interstriae longer, slender, pointed; basal area of spine 2 on elytral declivity more strongly elevated; Veneznela; Spondias mombin; 1.9-2.4 mm

2. analogus (Wood)

3(2). Lateral margins of elytral declivity armed by two pairs of spines; Costa Rica to Panama; Spondias mombin; 2.3-2.5 mm
3. fortis (Wood)

- Lateral margins of elytral declivity armed by one pair of spines: Panama; $2.3-2.6 \mathrm{~mm}$.......................................................................... 4. chiriquensis (Blandford)

## 1. Acanthotomicus mimicus (Schedl)

 Fig. 159Mimips mimicus Schedl, 1961. Pan Pacific Ent. 37:227 (Holotype, male: Turrialba, Costa Rica; Schedl Coll.)
Diagnosis.- This species is distinguished, with difficulty, from analogus (Wood) by the smaller size, by the weakly impressed lower frons of the male, by the finely serrate anterior margin of the pronotum, by the more poorly developed basal area of spine 2 on the elytral declivity, and by the shorter, stouter, blunt setae on the sutural interstriae of the declivity.

Male.- Length $1.6-2.0 \mathrm{~mm}, 2.5$ times as long as wide; color yellowish brown.

Frons convex, moderately, transversely impressed on slightly less than lower half, less strongly toward median line; surface mostly shining, rather coarsely punctured above, more finely and with sparse granules below; vestiture of rather sparse, coarse, long hair. Antennal club subcircular, with two rather strongly procurved sutures clearly marked by rows of setae, suture 1 not attaining middle of club.

Pronotum 1.1 times as long as wide; widest just behind middle, sides weakly arcuate, anterior margin broadly rounded; anterior margin armed by about 10 small serrations; summit not clearly defined; anterior slope moderately asperate; posterior area rather coarsely, not deeply punctured, shining except obscure reticulation toward summit on some specimens. Vestiture hairlike, confined to marginal areas.

Elytra 1.5 times as long as wide, 1.3 times as long as pronotum; sides almost straight and parallel on basal two-thirds, then convergently arcuate and truncate on slightly more than median half behind; striae not impressed, punctures moderately large, rather deep; interstriae as wide as striae, smooth, shining, punctures uniseriate, equal in size and appearance to those of striae but not quite as deep. Declivity steep, broadly excavated as in $I p s$; face of declivity broadly concave, punctures large, shallow, concave, sutural interstriae feebly elevated; lateral margins rather strongly elevated from interstriae 2 to sutural apex; interstriae 2 at base armed by a moderately large, pointed denticle, 3 armed by a slightly larger denticle; 4 and 5 armed by a rounded nodule, bases of denticle 2 on interstriae 3 and nodule on 4 connected, denticle 3 on margin at interstriae 6 as large as denticle 1 ; ventrolateral margin forming a continuous undulating costa from lateral margin at interstriae 7 to sutural apex. Vestiture of coarse, blunt, moderately short, interstrial setae, supplemented toward declivital base by shorter strial setae; sparse setae on declivital face short, blunt.

Female.-Similar to male except frons more broadly convex, impression scarcely indicated, finely, densely punctured, devoid of granules, ornamented by abundant, fine, long hair; denticles and nodules on elytral declivity slightly smaller.

Distribution.- Veracruz and Jamaica to Venezuela and Brazil.
\1EXICO: Veracruz: Lago Catemaco, I-3-V-69, D. E. Bright. COSTA RICA: Turrialba, Cartago, dry wood, F. Nevermann. PANAMA: Barro Colorado Island, Canal Zone, 27-XII-63, 70 m , No. 340. evidently Spondias mombin, S. L. Wood; Ft. Clayton, 22-XII-63, 35 m , No. 323, evidently Spondias mombin, S. L. Wood. OTHER COUNTRIES: 9 km S Barrancas, Barinas, Venezuela, 5-X1-69, 150 m , No. I15, Spondias mombin, S. L. Wood; 40 km E Cantón, Barinas, Venezuela, 8-III-70, 70 m , No. 394, Spondias mombin, S. L. Wood; Try., Good Hope. Jamaica, II-VIII-66, A. T. Howden.

Host. - Spondias mombin.
Brology.- This species was taken from slash and from broken, fallen limbs and branches. The habits are essentially as described for the genus. About three to five females were associated with a male. Parental and larval mines penetrated the entire phloem tissue; they were not confined to the cambium region. When in competition with analogus for space in the same branches, this species restricted its activity to branches 2 to 3 cm in diameter. In the absence of competition in Panama, it attacked limbs up to 8 cm in diameter.

Notes.- The above treatment was based on the holotype and on 155 other specimens.

This species bears a very strong resemblance to $I p s$ and, except for the antennal club, could very well be placed in that genus.

## 2. Acanthotomicus analogus (Wood)

Mimips analogus Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):40 (Holotype, male; 40 km E Cantón, Barinas, Venezuela; Wood Coll.

Although this Venezuelan species has not been reported from Central America, it is mentioned here because its host does occur there and because it probably would be overlooked if special attention were not called to its very close resemblance to mimicus Schedl. Information that will permit identification of it is presented in the above key and in the treatment of mimicus. It attacks the broken limbs and branches of Spondias mombin larger than 3 cm in diameter.

## 3. Acanthotomicus fortis (Wood)

Fig. 159
Mimips fortis Wood, 1971, Brigham Young Univ. Sci Bull., Biol. Ser. 15(3):40 (Holotype, male; Finca Taboga, about 15 km SW Cañas, Guanacaste. Costa Rica; W'ood Coll.)
Diagnosis.- This species is easily recognized by characters summarized in the above key.

Male.- Length 2.3-2.5 mm, 2.6 times as long as wide; color very dark brown.

Frons as in analogus except transverse impression much weaker; vestiture sparse, fine. Pronotum as in analogus except anterior margin indistinctly serrate, discal punctures slightly larger, not as close.

Elytra 1.5 times as long as wide; disc as in analogus but punctures very slightly smaller, deeper; strial and interstrial punctures equal in size. Declivity very steep, truncate, broadly concave; lower two-thirds margined by an

Fig. 159. Acanthotomicus spp., male elytral declivity: A, mimicus; B, fortis; C, granulatus. (After Wood 1971:39-41.)
elevated, subacute, continuous, slightly undulating ridge, upper third armed by two coarse teeth (directed caudad), one in line with interstriae 2 , second in line with interstriae 4; face of declivity shining, with moderately abundant, large, shallow punctures. Vestiture of rather long, fine, interstrial hair, a few supplemental setae near declivity.

Distribution.- Costa Rica to Panama.
COSTA RICA: Finca Taboga, about 15 km Sw Cañas, Guanacaste, 8 -II- 67 , presumably Spondias mombin. Pandand: Ft. Clayton, Canal Zone, 22-X11-63, 35 m , No. 340, presumably Spondics mombin, S. L. Wood.

Host.- Presumably Spondias mombin.
Brology.- The one specimen from Panama was taken with a series of mimicus (Schedl) from a limb presumed to be Spondias mombin. The habits evidently are very similar to those of mimicus.

Notes.- The above treatment was based on the type series of four male specimens.

## 4. Acanthotomicus chiriquensis (Blandford)

Xylocleptes chiriquensis Blandford, 1898, Biol. Centr. Amer., Coleopt. 4 (6):189 (Lectotype, male; British Mus. Nat. Hist., present designation)
Mimips chiriquensis: Wood. 1966. Great Basin Nat. 26:24
Diagnosıs.- This species is distinguished from granulatus (Ferrari) by the smooth, shining posterior areas of the pronotum, by the smaller punctures on the elytral dise, by the larger, stouter, posteriorly directed spines that are in line with striae 2 at the basal margin of the declivity, by the three or four minute denticles on the lateral margin of the male declivity, and by the smaller declivital punctures.

Male.- Length 2.3-2.6 mm, 2.7 times as long as wide; color reddish brown.

Frons and pronotum as in fortis (Wood) except anterior margin of pronotum more coarsely serrate, 1.1 times as long as wide, posterior area smooth, shining, punctures small, rather close, moderately deep.

Elytra 1.5 times as long as wide, 1.4 times as long as pronotum; sides straight and parallel on basal three-fourths, broadly rounded behind; striae not impressed, punctures very small, distinct; interstriae smooth, shining, 2 very shallowly impressed; interstriae slightly irregular, shining, at least six times as wide as striae, punctures almost uniseriate, as large as
those of striae but less clearly formed. Declivity rather abrupt, steep, broadly, shallowly concave; declivital face smooth, shining, with small, confused, rather close punctures, suture distinctly elevated; lateral margin distinctly, subacutely elevated on a circular are from sutural apex to striae 3 at base of declivity, a large, stout, pointed spine at declivital base on interstriae 2 , about one and onehalf times as long as its basal width, its apex directed toward elytral apex; central half of lateral margin bearing three widely spaced, pointed granules. Vestiture of coarse, moderately long, interstrial hair, similar setae on sutural interstriae of declivity.

Female.- Similar to male except major spine at base of declivity about half as large; lateral margin of declivity less strongly elevated (frons partly concealed by pronotum, remainder covered by glue).

Distribution.- Panama.
PANAMA: Volcán de Chiriquí, Chiriquí, $3-4,000 \mathrm{ft}$, G. C. Champion.

Notes.- The above treatment was based on Blandford's three syntypes. The first syntype, a male, is here designated as the lectotype of Xylocleptes chiriquensis Blandford.

## Genus IPS DeGeer

Ips DeGeer, 17T5. Mémoires pour servir à l'histoire des insectes 5:190 (Type-species: Tomicus typographus $=$ Dermestes typographus Linnaeus, subsequent designation by Bergroth, 1884. Berliner Ent. Zeitschr. 28:230
Cumatotomicus Ferrari, 1867, Die Forst- und Baumzuchtschädlichen Borkenkäfer, p. 44 (Typespecies: Bostrichus stenographus Duftschmidt $=B$. sexdentatus Boerner, subsequent designation by Hopkins, 1914, Proc. U.S. Nat. Mus. 48:119); Hagedorn, 1910, Coleopterorum Catalogus 4:47. Synonymy
Cyrtotomicus Ferrari, 1867, Die Forst- und Baumzuchtschädlichen Borkenkäfer, p. 44 (Typespecies: lps acuminatus Gyllenhal, subsequent designation by Hopkins. 1914, Proc. U.S. Nat. Mus. 48:120): Eichhoff, 1878, Mém. Soc. Roy. Sci. Liége, ser. 2, 8:254. Synonymy
Diagnosis.- This genus is distinguished from Orthotomicus Ferrari, as indicated in the diagnosis of that genus, and from Acanthotonicus Blandford by the strongly flattened antennal club, with sutures strongly to moderately bisinuate (except in concinnus and mexicanus), by the smaller, finely granulate eye, by the larger average size, and by the coniferous hosts.

Description.- Length 2.1-6.9 mm, 2.4-2.8 times as long as wide; color yellowish brown to almost black, vestiture hairlike.

Frons simple to strongly, sexually dimorphic. Eye finely faceted; small, shallowly emarginate, its width much less than length of scape, its length much less than twice length of scape. Antennal scape elongate; funicle 5 -segmented; club subcircular to oval, strongly flattened, two sutures on anterior face weakly bisinuate to strongly angulate. Pronotum about equal in length and width; summit near middle, not strongly developed; anterior slope strongly declivous, coarsely asperate, anterior margin not serrate; posterior area punctate. Scutellum rather large, flat. Elytra striate, declivity concavely excavated, lateral margins dentate, all teeth on summit, transverse length of ventrolateral subapical margin as wide as declivital excavation, strongly elevated. Tibiae as in other Ipini.

Distribution.- Coniferous forests of North America south to northern Nicaragua, Europe and Asia south to North Africa, India, and Australia; more than 60 species have been assigned to the genus; of these 25 occur in North America.

Biology.-All American species attack coniferous trees of the genera Pinus and Picea. Although most of them breed in slash, broken, fallen, or dying trees, some species under favorable conditions are capable of making successful primary attacks on healthy trees. They are polygamous and phloeophagous; the elongate egg galleries are in the cambium; eggs are deposited in individual niches (two exceptions). Larval mines are short to very long, straight to irregular, and always visible on peeled bark. From one to several generations per year may be produced.

Notes.- This genus intergrades with Orthotomicus and with Acanthotomicus. For the most part these groups are distinct and easily characterized. Exceptions occur with latidens (LeConte) and spinifer (Eichhoff), from North America, and erosus Wollaston, from Europe, which form a compact group having the general features of Orthotomicus, but the antennal club and the position of teeth on the elytral declivity place them in Ips. To make these genera definable, they are placed in Ips. The species concinnus (Mannerheim) and
mexicanus (Hopkins) are very closely related to one another, but they are intermediate in characters between Ips, Acanthotomicus and, perhaps, Orthotomicus. The antennal club is much as in some Acanthotomicus, the elytral declivity is somewhat like Orthotomicus, and the size, eye, hosts, frons, and other minor characters are as in Ips. Three possible solutions might be used to settle this problem: (1) accept an unsatisfactory grouping with the intermediate species grouped in definable, established genera; (2) group all these genera into one large genus, thus relegating the problem from the suprageneric level to the infrageneric level and, in my opinion, thereby magnify the problem that should be overcome; or (3) describe each of the intermediate groups as undefinable taxa that are even more difficult to recognize than those now available. As unsatisfactory as it is, the first alternative is followed below.

Since it often is desirable to divide a wellknown, economically important group into species groups, the following are suggested: concinnus group (concinnus and mexicanus), latidens group (latidens and spinifer), perturbatus group (perturbatus, perroti, woodi, and hunteri), tridens group (tridens, pilifrons, and borealis), pini group (pini, avulsus, and bonanseai), plastographus group (plastographus and integer), emarginatus group (emarginatus and knausi), calligraphus group (calligraphus), and grandicollis group (grandicollis, lecontei, montanus, paraconfusus, confusus, and hoppingi).

Of these nine species groups, that portion of the Palaearctic fauna known to me does not include representatives of the concinnus, tridens, or grandicollis groups. The Eurasian fauna includes representative of the latidens (erosus Wollaston), perturbatus (amitinus Eichhoff, cembrae Heer, duplicatus Sahlberg, fallax Eggers, subelongatus Molschulsky), pini (mannsfeldi Wachl), plastographus (hauseri Reitter, longifolia Stebbing, nitidus Eggers, stebbingi Strohmeyer, typographus Linnaeus), emarginatus (acuminatus Gyllenhal), and calligraphus (sexdentatus Boerner) groups. There are no Eurasian species groups of Ips known to me that are not represented in North America. The much greater diversity of the Nearctic fauna, coupled with the complete absence of unique Eurasian species groups, suggests an American origin of Ips.

Key to the Species of $I p s$

1. Elytral declivity steep, rather short, distance from anterior margin of elytra at scutellum to base of declivity on interstriae 1 much greater (more than 1.25 times) than distance from base of declivity to sutural apex of declivity; ventrolateral subapical margins of elytral declivity moderately produced, transversely much wider, circumscribing at least one-third of a circle, its lateral extremity ending near third (last and largest) denticle; antennal club with sutures 1 and 2 feebly or very strongly, broadly procurved

- Elytral declivity more gradual, distance from anterior margin of elytra at scutellum to base of declivity on interstriae 1 about equal to or less than distance from base of declivity to sutural apex of declivity; ventrolateral margin of elytral declivity very strongly produced, narrower, circumseribing an are much less than one-third of a circle, its lateral extremities ending remote from largest denticle (normally denticle 3), one or more additional denticles usually occurring between this point and denticle 3 (except emarginatus); sutures 1 and 2 of antennal club weakly bisinuate to strongly angulate
2(1). Larger; sutures on antennal club very strongly procurved; strial and interstrial punctures subequal in size, not always in clearly definable rows; spine 3 on declivity subcapitate, a distinct constriction before its apex; concinnus group
- Smaller; sutures on antennal club weakly procurved, almost straight; strial punctures at least twice as large as those of interstriae, in clearly defined rows; spine 3 on declivity cylindrical or conical, not constricted before its apex; latidens group
3(2). Punctures on posterior third of pronotum fine, close, those behind summit often finely granulate or connected by longitudinally strigose lines; pronotal vestiture more abundant, coarser; Alaska to N California; Picea sitchensis; $3.5-4.6 \mathrm{~mm}$ 1. concinnus (Mannerheim)
- Punctures on posterior third of pronotum moderately coarse, usually not at all granulate or strigose; pronotal vestiture finer, apparently less abundant; Alaska and Alberta to Guatemala; Pinus; 3.6-5.0 mm ....................... 2. mexicanus (Hopkins)
4(2). Frons granulate-punctate, granules small, inconspicuous; antennal club slightly larger, scape length about 1.2 times width of club; spine 3 on elytral declivity smaller, tapered from its base, usually not larger than 2, pointed; British Columbia and Quebec to California, Chihuahua, and West Virginia; Pinus; 2.3-3.6 mm

3. latidens (LeConte)

- Frons granulate-punctate, a pair of large granules near center; antennal club slightly smaller, scape length about 1.3 times width of club; spine 3 much larger than 2, not tapered on its basal two-thirds, usually blunt; California; Pinus sabiniana; $2.6-3.4 \mathrm{~mm}$

4. spinifer (Eichhoff)

5(1). Lateral margins of elytral declivity armed by four pairs of spinelike denticles (spine 3 in emarginatus group bifid); antennal club with sutures feebly to strongly bisinuate (angulate in integer group); frons with or without a prominent median tubercle, devoid of foveate impression6

- Lateral margins of declivity armed by five or six pairs of spines; antennal club with sutures strongly angulate; frons with a conspicuous median denticle (absent in some females) and, in most species, a subfoveate impression (impression always present when denticle absent)27

6(5). $\quad$ Smaller species; spine 3 on elytral declivity somewhat cylindrical, constricted or not

- Larger species; spine 3 on elytral declivity very large, strongly flattened and conspicuously emarginate at its tip (in some female knausi it may appear as two small denticles); emarginatus group

7(6). Discal interstriae irregularly, uniseriately punctured (perturbatus almost impunctate); spine 3 on male elytral declivity subcapitate, usually sharply pointed at its apex and directed caudodorsad; frons sexually dimorphic or not; hosts Picea (except woodi and perroti in Pinus)

- Discal interstriae impunctate except near declivity in some species; spine 3 on male declivity usually blunt, its apex slightly bent and directed somewhat caudoventrad; frons feebly if at all dimorphic; hosts Pinus

8(7). Frons similar in both sexes, broadly, almost uniformly convex, granulatepunctate, not unusually pubescent in female; perturbatus group

- Frons slightly to profoundly dimorphic, broadly convex and granulate-punctate in males, slightly to profoundly protuberant in females; tridens group
$9(8)$. Discal interstriae impunctate except near declivity; discal interstriae two to three times as wide as striae; strial punctures small, not noticeably reduced near declivity; punctures on pronotal dise small, shallow; Alaska and New Brunswick to Montana and Michigan; Picea; $4.0-4.7 \mathrm{~mm}$

5. perturbatus (Eichhoff)

- Discal interstriae at least sparsely punctured; discal interstriae distinctly less than twice as wide as striae; strial punctures near declivity about half as large as on disc

10(9). Smaller; slender, 2.7 times as long as wide; antennal club more slender, sutures almost straight; Alberta and New Brunswick to Minnesota and Michigan; Pinus; 2.7-3.5 mm
6. perroti Swaine

- Larger, stouter, 2.4-2.5 times as long as wide; antennal club wider, its sutures rather strongly bisinuate

11(10). Strial punctures coarse, deep, interstrial punctures at least half as large as those of striae; interstriae only slightly wider than striae; pronotal punctures rather coarse, deep; Alberta to Nevada and New Mexico; Pinus flexilis, P. strobiformis; 3.5-4.7 mm 7. woodi Thatcher

- Strial punctures moderately fine, interstrial punctures fine, less than half as large as those of striae; interstriae almost twice as wide as striae; pronotal punctures rather fine; Utah, Colorado, and Arizona; Picea pungens; 3.3-4.0 mm 8. hunteri Swaine

12(8). Smaller, 2.6-3.8 mm; surface of female frons above eyes smooth, even, punctures minute, lower frons weakly, rather broadly protuberant, its surface with small granules, sparse or absent (borealis Swaine)13

- Larger, 3.3-5.0 mm ; surface of female frons above eyes smooth; rather irregular, punctures moderately coarse, poorly defined, lower frons weakly to profoundly protuberant, part or all its surface usually rather coarsely granulate16

13(12). Female frons weakly protuberant on lower half, surface, at least at sides below and entire area above eyes, with very minute, almost obsolete punctures, granules minute or obsolete; epistoma without conspicuous granules

- Female frons almost evenly, broadly convex, sparsely pubescent over entire area below upper level of eyes, punctures small, distinct from epistoma to vertex; epistoma with a transverse row of granules

14(13). Female frons entirely glabrous, rather weakly inflated below, entire surface smooth, with sparse, minute punctures, entirely devoid of granules; Alaska and Montana to Newfoundland and Maine; Picea glauca; 3.0-3.7 mm
9. borealis borealis Swaine

- Female lower frons feebly to moderately inflated (variable), moderately to densely pubescent on median half below upper level of eyes, punctate area mostly very finely granulate; S British Columbia; Picea glauca, P. engelmannii; $2.6-3.4 \mathrm{~mm}$

10. borealis swainei R. Hopping

15(13). Female frontal pubescence rather short, very fine, lower frons not inflated, granules very small; SE Wyoming (?) and W South Dakota to Colorado; Picea glauca; 3.0-3.8 mm
11. borealis lanieri Wood

- Female frontal pubescence longer, coarser, lower frons feebly inflated, granules distinctly larger; Nova Scotia; Picea glauca; 3.2-3.6 mm

12. borealis thomasi G. Hopping

16(12). Average size smaller, $3.3-4.3 \mathrm{~mm}$; strial punctures smaller, not as deep, interstriae at least twice as wide as striae; Alaska to California and W Montana; tridens (Mannerheim) 17

- Average size larger, 4.4-5.0 mm; strial punctures coarse, deep, interstriae very slightly wider than striae; S Idaho and Montana to Arizona and New Mexico; pilifrons Swaine 18

17(16). Female frons feebly if at all elevated, granulate, sparsely pubescent; Alaska to California; Picea sitchensis; $3.8-4.3 \mathrm{~mm}$
13. tridens tridens (Mannerheim)

- Female frons moderately to profoundly protuberant from epistoma to upper level of eyes, granulate or not, glabrous to densely pilose; Alaska and Northwest Territories to California and Wyoming; Picea engelmannii, P. glauca; $3.3-4.3 \mathrm{~mm}$

14. tridens engelmanni Swaine

18(16). Female frons weakly if at all protuberant on lower half, granulation similar to male, vestiture sparse, partly or entirely fine and long; Wyoming and Utah to Colorado and Arizona; Picea engelmannii, P. pungens; 4.4-5.0 mm
17. pilifrons utahensis Wood

- Female frons moderately to very strongly protuberant below upper level of eyes, glabrous or vestiture of minute pile, granulation very different from male

19(18). Female frons strongly protuberant but elevated area strongly sulcate on median line, sides of sulcus glabrous to densely pilose; S Colorado to New Mexico; Picea pungens, $P$. engelmannii; $4.4-5.0 \mathrm{~mm}$

- Female frons moderately protuberant, without a deep median sulcus, pile, when present, more broadly distributed
20(19). Female frontal protuberance occupying lower 80 percent (maximum development) of distance from epistoma to upper level of eyes, pilose area confined to median 50 percent of distance between eyes, lateral areas more sparsely, finely granulate; Mt. Wheeler, Nevada; Picea engelmannii; 3.9-4.9 mm

18. pilifrons thatcheri Wood

- Female frontal protuberance occupying 115 percent (maximum development) of distance from epistoma to upper level of eyes, pilose area confined to median 80 percent of distance between eyes, lateral areas more coarsely, closely granulate; north central Colorado to SW Wyoming; Picea engelmannii; 4.0-5.0 mm
21(7). Sutures 1 and 2 on antennal club broadly bisinuate; lower frons regularly granulate, without a median tubercle, fovea, or carina; smaller, 2.1-4.3 mm; pini group
- Sutures 1 and 2 on antennal club strongly bisinuate, acutely angulate at middle; lower frons with a median tubercle, carina, or fovea; larger, 4.2-5.4 mm ; plastographus group24
$22(21)$. Interstriae little if any wider than striae; ventrolateral margin of elytral declivity moderately, subacutely extended; declivital spines forming short, blunt cones, spine 3 not capitate in male; Wisconsin and New Jersey to E Texas and Florida; Pinus; 2.1-2.8 mm

19. avulsus (Eichhoff)

- Interstriae at least one and one-half times as wide as striae; ventrolateral subapical margin of declivity very strongly, acutely extended; declivital margin usually higher, more acutely pointed, spine 3 capitate in male
23(22). Major median frontal tubercle connected by a carina to epistomal tubercle; pronotal dise usually more uniformly punctured, punctures in posterolateral areas little if any larger than those behind summit; punctures on pronotal dise usually less than one-third as large as strial punctures; S Arizona to Honduras; Pinus; 2.9-3.4 mm

20. bonanseai (Hopkins)

- Frons without a major median tubercle or elevation; pronotal punctures behind summit less dense and much smaller than those in posterolateral areas, largest punctures at least two-thirds as large as those of striae; Alaska and Newfoundland to Chihuahua and North Carolina; Pinus; 3.3-4.3 mm

21. pini (Say)
24(21). Median epistomal and frontal tubercles usually connected by a continuous carinate elevation; strial punctures at middle of dise often subquadrate or wider than long; interstriae 3-5 rarely with punctures near declivity, those present uniseriate; British Columbia and South Dakota to Guatemala; Pinus;

- Median epistomal (if present) and frontal tubercles rarely connected by a carina; strial punctures usually smaller, circular; interstriae 3-5 commonly punctured on posterior third of dise, those present usually confused; smaller 25

25(24). $\begin{aligned} & \text { Median frontal tubercle moderately developed; striations on female stridula- } \\ & \text { tory organ (pars stridens) on vertex more closely spaced; struts on male ae- } \\ & \text { deagus proportionately longer; British Columbia and Wyoming to central Cali- } \\ & \text { fornia; Pinus contorta; } 4.0-5.2 \mathrm{~mm} . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . ~\end{aligned}$ 23. plastographus plastographus (LeConte)

- Median frontal tubercle rather poorly developed; striations on pars stridens more widely spaced; struts on male aedeagus proportionately shorter; Oregon and California coasts; Pinus radiata, P. murricata, P. contorta, $4.0-5.1 \mathrm{~mm}$

## 24. plastographus maritimus Lanier

26(6). Interstrial punctures absent; declivital spine 4 absent (rarely present in female); British Columbia and E Montana to Baja California; Pinus; 5.5-6.9 mm
25. emarginatus (LeConte)

- Interstrial punctures present; declivital spine 4 present; S Nevada and E South Dakota to Arizona and New Mexico; Pinus ponderosa; 4.9-6.4 mm

26. knausi Swaine

27(5). Subapical margin of elytral declivity transversely short, equal to about twofifths distance between largest (third) spines; lateral margins armed by six pairs of spines; California and Quebec to Jamaica and Honduras; Pinus; 3.8-5.9 mm
27. calligraphus (Germar)

- Subapical margin of elytral declivity longer, equal to three-fourths distance between largest (third) spines; lateral margins armed by five pairs of spines28

28(27). Distance from spine 2 to spine 1 on elytral declivity conspicuously greater than
from spine 1 to suture ..... 29

- Distance from spine 2 to spine 1 equal to or less than from spine 1 to suture ..... 30
29(28). Male frons armed by one median tubercle placed well above epistoma; Mani-toba and Quebec to Florida and Honduras; Pinus: 2.9-4.6 mm

28. grandicollis (Eichhoff)

- Male epistoma armed at median line by a pair (transverse) of tubercles; Arizona and New Mexico to Honduras; Pinus; $4.0-4.7 \mathrm{~mm}$......... 29. lecontei Swaine
$30(28)$. Frontal fovea poorly developed in both sexes; upper margin of enlarged median tubercle on male frons comparatively remote from epistoma, attaining upper level of eyes; frontal vestiture usually not as long or as abundant; British Columbia and W Montana to California; Pinus monticola; 4.6-5.4 mm

30. montanus (Eichhoff)

- Frontal fovea usually deeply impressed in both sexes; emlarged median tubercle on male frons almost on epistoma, remote from upper level of eyes; frontal vestiture usually more abundant, longer; smaller than 4.3 mm31
$31(30)$. Frons almost always with a few small, often obscure punctures in central area among granules; major tubercle on male frons usually larger, more broadly rounded; punctures on elytral declivity smaller, more widely spaced; S Oregon to California and W Nevada; Pinus ponderosa; $3.8-4.3 \mathrm{~mm}$

31. paraconfusus Lanier

- Frons almost always entirely devoid of punctures; major tubercle on male frons usually smaller, more acutely pointed; punctures on declivity slightly larger, their abundance greater and spacing closer; S California and Colorado to Baja California and W Texas; pinyon pines; 3.5-4.2 mm

32. confusus (LeConte) and 33. hoppingi Lanier

## 1. Ips concinnus (Mannerheim)

Bostrichus concinnus Mannerheim, 1852. Moskov: Obshch. Isp. Prirody, Otd. Biol. Biul. (Bull. Soc. Imp. Nat. Moscou) 25:358 (reprint p. 76) (Lectotype, sex?; Sitka Island, Alaska; Univ. Zool. Mus. Helsinki, present designation)
Tomicus hirsutus Eichhoff, I865, Berliner Ent. Zeitschr. 11:402 (Syntypes?: Sitka, Alaska; presumably lost with Hamburg Mus.); Eichhoff. I878, Mém. Soc. Roy. Sci. Liége (2)8:233. Synonymy
Ips chamberlini Swaine, 1925, Canadian Ent. 57:196 (Holotype, female?: Astoria, Oregon; Canadian Nat. Coll., 1376); Wood, 1957, Canadian Ent. 89:397. Synonymy
Diagnosis.- This species is distinguished from the closely allied mexicanus (Hopkins) by the finer, closer punctures on the pronotum, with those behind the summit often finely granulate or connected by longitudinal strigose lines, by the slightly more abundant pronotal vestiture, and by the host.

Male.- Length 3.5-4.6 mm, 2.5 times as long as wide; color dark reddish brown.

Frons broadly convex, a large, somewhat subfoveate, median impression just below upper level of eyes; epistomal margin rather shallowly emarginate, a slight impression in lateral area above epistoma; surface shining, closely, rather coarsely granulate, granules gradually replaced above eyes by punctures; median area between fovea and epistoma occupied by a large, blunt tubercle; vestiture sparse, inconspicuous. Antennal club with sutures poorly formed, strongly procurved, suture 1 reaching middle.

Pronotum 1.03 times as long as wide; widest at base, sides feebly arcuate, converging very slightly on basal half, broadly rounded in front; summit at middle; anterior slope rather finely asperate; posterior area shining, finely, deeply, rather closely punctured, a few punctures behind summit subasperate. Vestiture of fine, long, rather abundant hair.

Elytra 1.5 times as long as wide; sides almost straight and parallel on basal threefourths, narrowed slightly before broadly truncate apex; striae not impressed; strial and interstrial punctures of equal size and appearance, small deep, confused or (sometimes) strial punctures in indistinct rows. Declivity steep, deeply, broadly excavated; surface of concavity shining, punctures small, confused, rather close; lateral margins armed by three pairs of spines; spine 1 rather small, acutely pointed, in line with striae 2 ; spine 2 larger, acute, in line with striae 3, its elevated basal area extending as a crest twothirds distance to spine 3 ; spine 3 much larger, cylindrical, subcapitate, evidently in line with striae 6 ; posterolateral subapical margin strongly, acutely elevated from suture to just below and equal to lateral margin of spine 3. Vestiture of rather abundant, fine, long hair.

Female.- Similar to male except major, median, frontal tubercle greatly reduced or absent; declivital spines 1 and 2 very slightly smaller, 3 distinctly smaller and usually not subcapitate.

Distribution.- Coastal margin of Alaska to N California.

ALASKA: Edna Bay on Kosciusko lsl., Hollis, Hower, Juneau, Seagull Creek, Seward. CANADA: British Columbia: Massett on Queen Charlotte lsl., Stanley Park. USA: California: Crescent City. Oregon: Astoria (probably accidental), Currie Co., Florence, Mary's Peak (in flight), Newport, Otis, Seaside. Washington: Hoquiam.

Host.-Picea sitchensis.
Brology. - The bole of cut or fallen trees is selected for attack. The parental galleries are constructed mostly in the phloem, scoring the wood very lightly. The three to five egg tunnels associated with each male are strongly curved. The egg niches are very large and each may contain about three to six (usually four) eggs. The larval mines radiate from the parental galleries on a somewhat long, irregular course. Pupation occurs in the bark. Young adults may feed for an extended period before emerging from the brood host.

Notes.- Of the five specimens of this species in the Mannerheim collection, only the two collected by Frankenhaeuser are eligible for consideration as syntypes. Of these one has been labeled Bostrichus concinnus sp. n. by Mannerheim and has subsequently had a red type label attached to its pin. 1 designate
this specimen as the lectotype of B. concinnus Mannerheim. In addition to the Mannerheim series, the holotype of chamberlini and 206 other specimens were examined. Authentic specimens of hirsutus have not been located; I see no reason to question the synonymy proposed for this name by Eichhoff, because mexicanus is not known to occur as far north as the type locality of hirsutus and the description eliminates the possibility of confusing it with any other species.

The type series of chamberlini was taken at Astoria, Oregon, from Douglas fir. This inland record from an abnormal host suggests that infested logs of Sitka spruce might have been transported to Astoria, where specimens emerged and, under stress, entered the abnormal host. Both the locality and the host are abnormal for this species.

## 2. Ips mexicanus (Hopkins)

Fig. 160

Tomicus mexicanus Hopkins, 1905, preprint of Proc. Ent. Soc. Washington 7:75 (Lectotype, female: Mexico City, Mexico; U.S. Nat. Mus., 7513, present designation)
Ips radiatae Hopkins, 1915, Proc. Ent. Soc. Washington 17:54 (Holotype, female?; Berkeley, California; U.S. Nat. Mus., 7461 ); Hopping, 1963, Canadian Ent. 95:1094. Synonymy
$\mathrm{D}_{\text {Iagnosis.- }}$ This species is distinguished from the closely allied concinnus (Mannerheim) by the more coarsely punctured pronotal disc, the punctures usually not at all granulate, by the slightly less abundant pronotal hair, and by the host.

Male.- Length 3.6-5.0 mm, 2.5 times as long as wide; color dark reddish brown.

Frons as in concinnus except tubercles arming epistomal process much coarser and central fovea averaging deeper. Pronotum as in concinnus except punctures in posterior area distinctly larger, not as dense, those behind summit not granulate; vestiture slightly less abundant. Elytra as in concinnus except punctures averaging slightly larger.

Female.- Similar to male except differing as in concinnus.

Distribution.-Alaska and Alberta to Guatemala.

ALASKA: Douglas Island, Juneau. CANADA: Alberta: Cameron Lake. British Columbia: Aspen Grove, Field, Hope Mts., Kane Valley, Nahun, Pender Harbor. USA: Arizona: Williams. California: Alameda Co., Berkeley,

Contra Costa Co., Del Monte, Del Norte Co., El Dorado Co., Gasquette R.S., Inverness, Lake Eiler in Lassen N.F., Lake Valley, Los Angeles, Meyers, Monterey, Oakland, Pacific Grove, Palo Alto, Placerville, San Bernardino Co., San Francisco, Santa Barbara Co., Santa

Clara Co., Santa Cruz Co.. Trinity Co.. Tulare Co., Yosemite. Colorado: Gould, Hahn's Peak, Littleton, Poudre Canyon in Larimer Co. Idaho: Coeur d'Alene, Krassel, Payette, Priest River, Utah Co. Montana: Bozeman, Columbia Falls, Glacier N.P., Sula. Oregon:

Fig. 160. Ipini declivities and heads: 19, Ips erosus (Europe); 20, Ips latidens, male; 21, Ips spinifer, female; 22, Orthotomicus eaelatus, female; 23, Ips plastographus, male; 24, Ips mexicanus; 25, Pityokteines lasioearpi, female; 26-27, Pityokteines elegans, female. (After Hopping 1963:65).

Badger Creek, Crater Lake N.P., Joseph, Ochoco N.F., Santiam Pass, Seaside. Utah: Elk Park in Ashley N.F., Kamas, Logan Canyon, Mirror Lake in Summit Co., Soapstone Creek in Uinta N.F. Wyoming: Bighorn N.F., Cheyenne, Cody, Keystone, Saratoga, Teton N.P., Wapiti, Washakie. MEXICO: Baja California: Guadeloupe Isl. Distrito Federal: Mexico City. Chiapas: San Cristóbal. Durango: La Ciudad, El Salto. Hidalgo: Tulancingo, Zacatlán, Zimapán. Mexico: Amecameca. Michoacán: Carapan. Puebla: Texmelucan. Veracruz: Perote, Las Vegas, Jacal. GUATEMALA: San Cristóbal, Totonicipan.

Hosts.-Pinus attenuata, P. contorta, $P$. cooperi, P. durangensis, P. hartwegii, P. leiophylla, P. montezumae, P. muricata, P. pseudostrobus, P. radiata.

Biology.- Although consistent anatomical characters are not apparent, the habits of the Canadian-United States population is different from the Mexican-Guatemalan population. In the United States stumps or the butt of dying, standing trees are attacked at or near ground level. The gallery systems are essentially as in concinnus except they engrave the wood more deeply. The MexicanGuatemalan form attacks the bole of standing trees well above the ground level ( 2 m or more) and may occur in felled material. The egg galleries are straight (longitudinal) for at least two-thirds of their length, with the terminal third curved.

Notes.- The holotypes of both mexicanus Hopkins and radiatae Hopkins were examined in addition to 147 specimens from Canada and the United States, and 42 specimens from Mexico and Guatemala.

Several characters, such as the biology, coarseness of elytral punctures, length and texture of declivital setae, and height of the subapical margin of the declivity, might be used to separate mexicanus and radiatae into allopatric species. However, these characters are not sufficiently consistent in the material at hand to warrant such a separation. A more detailed analysis of additional material is required before a final conclusion should be made concerning the taxonomic status of these populations.

## 3. Ips latidens (LeConte) Fig. 160

[^11]Coll., 9299, designated by Bright, 1967, Canadian Ent. 99:676); Hopping, 1963, Canadian Ent. 95:64. Synonymy
Ips guildi Blackman, 1922, New York St. Coll. For., Syracuse, Tech. Publ. 16:137 (Holotype, female; Grand Lake, Colorado; U.S. Nat. Mus.); Hopping. 1963, Canadian Ent. 95:64. Synonymy
Diagnosis.- This species is distinguished from the closely allied spinifer (Eichhoff) by the smaller, less conspicuous frontal granules, by the larger antennal club, and by the smaller, tapered spine 3 on the elytral declivity.

Male.-Length 2.3-3.6 mm, 2.7 times as long as wide; color dark reddish brown.

Frons broadly, weakly concave, a shallow, transverse impression on lower half; surface smooth, shining, with small, rather sparse granules, granules intermixed with punctures above eyes; epistomal margin shallowly emarginate, vestiture of sparse, long hair, epistomal brush conspicuous. Antennal club flattened, sutures weakly procurved.

Pronotum 1.2 times as long as wide; sides almost straight on basal half, broadly rounded in front; summit slightly anterior to middle; anterior slope rather coarsely asperate; posterior area smooth, shining, punctures moderately coarse, deep, moderately close. Vestiture of moderately abundant, fine, long hair.

Elytra 1.5 times as long as wide; sides almost straight and parallel on basal threefourths, slightly narrowed at declivity, trumcate behind, with median half feebly subemarginate, spine 3 projecting; striae 1 moderately, others weakly impressed, punctures, coarse, deep; interstriae as wide as striae, smooth, shining, weakly convex, punctures fine, uniseriate. Declivity steep, broadly, deeply excavated; surface of concavity smooth, shining, punctures rather coarse, deep, moderately close; lateral margins strongly elevated, armed by "three pairs of denticles; spine 1 moderately large, acutely pointed, in line with striae 2 , spine 2 slightly larger, acutely pointed, its basal margin continuing two-thirds of distance to spine 3, spine 3 much larger, conical, tapered from its base to subacute apex; subapical ventrolateral margin rather strongly, acutely elevated, extending from suture to just below spine 3, occupying more than one-third of a complete circle. Vestiture of fine, long, rather abundant hair, except very short on declivity.

Female.- Similar to male except declivital excavation not quite as deep, spines 1 and 2 slightly smaller, spine 3 distinctly smaller.

Distribution.-S British Columbia and Quebec to California, Chihuahua, and West Virginia.

CANADA: Alberta, British Columbia, Ontario, Quebec, Saskatchewan. USA: Arizona, California, Colorado, ldaho, Massachusetts, Montana, New Hampshire, New Mexico, New York, Oregon, Pennswania, Utah, Washington, West Virginia, Wyoming. MEXICO: Chihuahua: Cusarara, San Juanito.

Hosts.-Pinus albicaulis, P. contorta, $P$. edulis, P. flexilis, P. jeffreyi, P. lambertiana, P. monticola, P. ponderosa, P. strobus.

Biology.- Unthrifty or broken limbs are most commonly selected for attack, although the bole may also be utilized. The egg galleries are comparatively short; they tend to be longitudinal; there are from two to about five egg galleries associated with each large nuptial chamber. The eggs are deposited in individual niches. The larval mines are moderately long.

Notes.- The holotypes of latidens and guildi, the lectotype of longidens, and 267 other specimens were examined.

Due to an error in the identification of latidens, Blackman named guildi and placed spinifer as a synonym of latidens. This error also led to the description of sabinianae, a synonym of spinifer.

The anatomical differences between eastern and western populations of this species appear to be of insufficient magnitude or importance to justify the recognition of geographical races.

## 4. Ips spinifer (Eichhoff)

Fig. 160
Tomicus spinifer Eichhoff, 1878, preprint of Mém. Soc. Roy. Sci. Liége (2)8:499 (Holotype, sex?: California; presumably lost with Hamburg Mus.)
Orthotomicus sabinianae G. Hopping, 1963. Canadian Ent. 95:64 (Holotype, male: Middletown, Lake Co., California; California Acad. Sci.); Wood, 1973, Great Basin Nat. 33:177. Synonyny
Diagnosis.- This species is distinguished from the closely related latidens (LeConte) by a pair of enlarged frontal tubercles, by the larger antennal club, and by the larger, untapered spine 3 on the elytral declivity.

Male.- Length $2.6-3.4 \mathrm{~mm}, 2.7$ times as long as wide; color reddish brown.

Frons as in latidens except slightly more strongly concave, with lateral impressions immediately above epistoma slightly deeper, granules averaging slightly larger; a transverse pair of very coarse, submedian tubercles just below upper level of eyes; epistomal margin armed by a uniseriate row of granules, lateral ones rather coarse. Antennal club apparently averaging larger than latidens, with sutures less strongly procurved.

Pronotum and elytral dise essentially as in latidens. Declivity as in latidens except spine 3 larger, cylindrical, not tapered from base, apex appearing somewhat subcapitate or bent ventrad.

Female. - Similar to male except major tubercles at center of frons and on epistoma slightly smaller; spine 3 on declivity usually slightly smaller.

Distribution.- California and possibly S Oregon.

USA: California: Alameda Co., Amador Co., Arroyo Valley, Auburn. Butte Co., Calaveras Co., Colusa Co.. Contra Costa Co., Shingle Springs in El Dorado Co.. Kern Co., Lake Co., Los Angeles Co., Madera Co., Mariposa Co., Monterey Co., Morgan, Mt. Diablo, Napa Co., Nevada Co., North Fork, Placerville, Red Bluff, Redding, Riverside, Sacramento, San Andres, San Diego. San Diego Co., San Luis Obispo Co., Santa Barbara Co., Santa Clara Co., Shasta Co.. Siskiyou Co., Solano Co., Trinity Co., Tuolumne Co, Weaverville. Yolo Co.

Host.- Pinus sabiniana.
Biology.- Basically as in latidens except that apparently only the lower bole and stump are attacked.

Notes.- The above treatment was based on 19 paratypes of sabinianae and on 95 other specimens.

## 5. Ips perturbatus (Eichhoff) <br> Fig. 161

Tomicus perturbatus Eichhoff, 1869. Berliner Ent. Zeitschr. 12:274 (Syntypes?: Amerique boreali; presumably lost with Hamburg Mus.)
Tomicus hudsonicus LeConte, 1876, Proc. Amer. Philos. Soc. 15:366 (Lectotype, female: Hudson Bay Territory: Mus. Comp. Zool., 26, present designation); Swaine, 1918, Dom. Canadian Dept. Agric. Ent. Br. Tech. Bull. 14(2):115. Synonymy
Tomicus interpunctus Eichhoff, 1878, Mém. Soc. Roy: Sci. Liége (2)8:241 (Syntypes?; Sitka, Alaska; presumably lost with Hamburg Mus.); Wood, 1977, Great Basin Nat. 37:386. Synonymy
Diagnosis.- This species is distinguished from pini (Say) and hunteri Swaine by the larger body size, and by the smaller strial

Fig. 161. Ips spp.: 1-3, perturbatus, male, 4, same, female; 5, hunteri, male; 6, woodi, male, 7-8, 11, same, female; 10, pilifrons utahensis, female. (After Hopping 1965:536.)
punctures with proportionately wider interstriae. It has some interstrial punctures near the declivity, fewer than hunteri, but more than pini.

Male.- Length $4.0-4.7 \mathrm{~mm}, 2.6$ times as long as wide; color dark brown.

Frons broadly, rather evenly convex, shining; surface rather coarsely, deeply, closely punctured, punctures gradually replaced by moderately large, isolated, rounded tubercles below, a transverse pair near center distinctly larger; a uniseriate row of tubercles on epistomal margin; vestiture of rather sparse, fine, long hair.

Pronotum 1.07 times as long as wide; sides almost straight and parallel on basal half, rather broadly rounded in front; summit at middle; anterior slope rather coarsely asperate; posterior aréa smooth, shining, punctures rather small, deep, moderately close. Vestiture of moderately abundant, fine, long hair, except glabrous on small discal area.

Elytra 1.4 times as long as wide, 1.4 times as long as pronotum; sides straight and parallel on basal two-thirds, converging slightly before broadly rounded posterior margin, apex slightly produced, then narrowly emarginate at suture; striae feebly impressed, punctures moderately coarse, deep; interstriae smooth, shining, weakly convex, impunctate on basal half, posterior half with fine, uniseriate punctures at least near declivity, commonly extending anteriorly as far as middle of disc. Declivity moderately steep, broadly excavated; face of concave area smooth, punctures rather sparse, coarse, confused; lateral margins strongly elevated, armed by four pairs of spines; spine 1 immediately mesad of striae 2 , pointed, moderately coarse, 2 in line with striae 3 , slightly larger than 1 , sharing base with spine 3 ; spine 3 distinctly larger than 2 , capitate, with apex pointed, not bent; spine 4 as large as 2, blunt, intermediate in position between spine 3 and lateral end of elevated, transverse, subapical costa; subapical costa strongly, acutely elevated, equal in total transverse length to distance between mesal surfaces of spine 3, its arc completing about one-fourth of a circle. Vestiture confined to sides and base of declivity, of long, slender hair.

Female.-Similar to male except declivital spines very slightly smaller.

Distribution-Alaska and New Brunswick to Montana and Michigan.

ALASKA: Fairbanks, Glennallen, Kenai Peninsula, Larstrum, Mentasia, Middle fork of Chandler River, Sheenjek River, Talkeetna. CANADA: Alberta: Athabasca Landing, Andrew, Banff Springs, Calgary, Edmonton, Lesser Slave Lake, Nordegg, Whirlpool River at Jasper. British Columbia: Fort John, Glacier, Hope Mt., Kaslo, Likely, Lower Post, Polly River Crossing, Nicola, Stanley, Trinity Valley. Manitoba: Aweme, Gillan, Onah, Red Deer. New Brunswick: Bathurst, Nictor Lake. Northwest Territories: Aklavik, Ft. McPherson. Ontario: Frater, Lake of the Woods, Monteith, Nakina, Ogoki, Ottawa, Petawawa. Quebec: Aylmer, Gaspé, Mistassini, Rupert House, Trinity Bay. Saskatchewan: Cypress Hills, Regina, Yukon Territory: Elsa, Kluane Lake, Rampart House, Snag, Swim Lake, Whitehorse. USA: Maine: Camp Caribou. Michigan: Marquette, Lake Superior. Minnesota: Duluth, Ely in Lake Co. Montana: Arlee.

Host.-Picea glauca, one record from $P$. engelmannii.

Biology.- Apparently the boles of unthrifty, cut, or fallen trees are selected for attack. The parental tunnels are of the typical tuning fork pattern; the moderately long larval mines radiate from them.

Notes.- The above treatment was based on the syntypes of hudsonicus and on 351 other specimens. The first syntype of hudsonicus in the LeConte collection bears a "type" label and another "Type No. 21." That specimen is here designated as the lectotype of Tomicus hudsonicus LeConte. Apparently other representatives of the original series were sent by LeConte to Eichhoff, who (Eichhoff 1878:250) referred them to perturbatus. The size and original description also make it possible to recognize this species in the absence of a type.

The type locality of interpunctus is Sitka, Alaska. The original description indicates that the type was 4.0 mm long, it had a transversely arranged pair of coarse tubercles on the frons, and the basal parts of the elytral interstriae were impunctate. Because only perturbatus and tridens (Mannerheim) occur on Sitka Island, and because size and both characters fit perturbatus, but not tridens, interpunctus is placed in synonymy.

This species is very similar to typographus (Linnaeus) of Eurasia, but that species has only one median frontal tubercle and a dull surface on the elytral declivity.

## 6. Ips perroti Swaine <br> Fig. 165, 166

Ips perroti Swaine, 1915, Canadian Ent. 47:356 (Holotype, male; Isle Perrot, Quebec; Canadian Nat. Coll., 9301)
Diagnosis.- This species is distinguished from woodi Thatcher by the smaller size, by the more slender form, and by the more slender antennal club with the sutures almost straight.

Male.- Length 2.7-3.5 mm, 2.7 times as long as wide; color dark reddish brown.

Frons essentially as in perturbatus except with only one major tubercle on median line almost on epistoma; epistomal tubercles progressively larger toward median line.

Pronotum 1.23 times as long as wide; essentially as in perturbatus except entire discal area devoid of pubescence.

Elytra 1.6 times as long as wide; outline essentially as in perturbatus; striae 1 weakly, others not impressed, punctures rather coarse, deep; interstriae one and one-half times as wide as striae, smooth, shining, basal half impunctate, posterior half with sparse, coarse, rather deep punctures. Declivity about as in perturbatus except punctures in concave area larger; spine 1 in line with striae 2; spine 2 with apex curved more nearly caudad, its base more closely associated with base of spine 3 , spine 3 very stout, not capitate, with a small point at apex; spine 4 as large as 2 but blunt. Vestiture restricted to sides and base of declivity, of very long, rather abundant hair.

Female.- Similar to male except declivital spines slightly smaller, more slender, spine 3 much more slender, conical, pointed.

Distribution.-Alberta and New Brunswick to Minnesota and Michigan.

CANADA: Alberta: McLeod, Peace River, Strachen, Watino. Manitoba: Aweme, Victoria Beach. New Brunswick: Salmon River. Ontario: August, Constance Bay, Nester Falls, Petawawa. Quebec: Aylmer, Ft. Coulonge, Isle Perrot. USA: Michigan: Roscommon. Minnesota: Cloquet, Lake Itasca, Itasca Park, Wandena Co.

Hosts.- Pinus banksiana, P. resinosa.
Biology. - The bole and larger limbs of unthrifty, cut, or fallen trees are usually selected for attack. The parental gallery pattern is essentially as in perturbatus; however, the larval mines are very short and usually curve back toward their origins, with pupation occurring near the egg tunnel.

Notes.- The above treatment was based on the holotype and on 194 other specimens.

## 7. Ips woodi Thatcher

Fig. 161

Ips woodi Thatcher, 1965, Canadian Ent. 97:493 (Holotype, female; Beaver Creek, Logan Canyon, Utah; U.S. Nat. Mus.)
Diagnosis.- This species is distinguished from perroti Swaine by the larger size, by the stouter body form, by the bisinuate sutures of the antennal club, and by the distribution.

Male.- Length $3.5-4.7 \mathrm{~mm}, 2.4$ times as long as wide; color very dark brown to almost black.

Frons moderately convex, with a weak, narrow, transverse impression just above epistoma; surface shining, coarsely, closely granulate from epistoma to well above eyes, coarsely punctured toward vertex; vestiture of sparse, fine hair. Antennal club with suture 1 strongly bisinuate, 2 obtusely angulate.

Pronotum 1.1 times as long as wide; essentially as in perturbatus except punctures on posterior areas rather coarse. Vestiture of fine, long hair, except disc glabrous.

Elytra 1.5 times as long as wide; outline essentially as in perturbatus except apex evenly rounded, sutural notch almost obsolete; striae 1 moderately, others feebly impressed, punctures rather coarse, deep, except distinctly smaller at base and near declivity; interstriae smooth, shining, slightly wider than striae, impunctate on basal fourth of dise, sparsely, uniseriately, rather finely punctured behind. Declivity as in perturbatus.

Female.- Similar to male except declivital spines slightly smaller.

Distribution.-S Alberta to Nevada and New Mexico.

CANADA: Alberta: Bellevue R.S., Burmis. USA: Arizona: 20 miles $S$ Alpine in Greenlee Co.; San Francisco Peaks. Idaho: Elk City in Nezperce N.F. Montana: Coal Creek in Glacier N.P. Nevada: Bear Creek Summit in Elko Co. New Mexico: Cloudcroft. Utah: Huntington Canyon, Logan Canyon. Wyoming: Atlantic City.

Hosts.-Pinus flexilis and P. strobiformis.
Biology.- The large limbs and bole of unthrifty, cut, and fallen trees are selected for attack. The gallery patterns are typical of the genus, with the parental system longitudinal, resembling a narrow tuning fork.

Notes. - The above treatment was based on the holotype, on 13 paratypes, and on 160 other specimens.

## 8. Ips hunteri Swaine <br> Fig. 161

Ips hunteri Swaine, 1917, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(1):31 (Holotype, female?; Creede, Colorado; Snow Ent. Mus., Univ. Kansas)
Diagnosis. - This species is distinguished from perturbatus (Eichhoff) by the smaller size, by the larger strial punctures and proportionately narrower interstriae, and by the distribution.

Male.- Length $3.3-4.0 \mathrm{~mm}, 2.5$ times as long as wide; color very dark brown to almost black.

Frons as in perturbatus except pair of major tubercles usually much smaller. Pronotum as perturbatus except punctures slightly coarser, but finer than in woodi Thatcher.

Elytra 1.5 times as long as wide; as in woodi except strial punctures slightly smaller; interstriae usually with more minute, impressed points, about one and one-half times as wide as striae; a greater tendency for interstriae 1 to bear a series of rounded tubercles on posterior half.

Female.- Similar to male except declivital spines slightly smaller.

Distribution.- Utah and Colorado to N Arizona.

USA: Arizona: Kaibab N.F., Safford. White River. Colorado: Creede, Poudre Canyon in Larimer Co., Rico in Dolores Co. Utah: Beaver, Huntington Canyon, Panguitch, Parowan Canyon, Sanford Canyon in Dixie N.F., Wolf Creek Pass.

Hosts. - Picea pungens, less common in $P$. engelmannii.

Biology.- The boles of unthrifty, cut, or fallen trees are attacked. The egg galleries are comparatively short and are not oriented with the grain of the wood; they may be diagonal, transverse, or longitudinal, curved or straight.

The normal host is Picea pungens; records from $P$. engelmannii usually prove to be roosting records, misidentified host, or result from unusual local conditions.

Notes. - The above treatment was based on the holotype, on 3 paratypes, and on 96 other specimens.

## 9. Ips borealis borealis Swaine Fig. 162

Ips borealis Swaine, 1911, Canadian Ent. 45:213 (Lectotype, female; St. Anthony, Newfoundland: Canadian Nat. Coll., 9302, designated by Bright. 1967, Canadian Ent. 99:675)
Diagnosis.- This species is distinguished from tridens Mannerheim by the smaller size, and by the very different sculpture of the female frons. The female frons is glabrous and entirely smooth.

Female.- Length $3.0-3.7 \mathrm{~mm}, 2.5$ times as long as wide; color dark brown.

Frons convex above, moderately protuberant from just below upper level of eyes to epistoma; surface dull, entirely smooth, devoid of all indications of punctures and granules; glabrous except for conspicuous epistomal brush. Antennal club with suture 1 weakly, 2 moderately bisinuate.

Pronotum 1.1 times as long as wide; essentially as in perturbatus except punctures in posterior areas slightly larger and less regular in size.

Elytra 1.5 times as long as wide; essentially as in perturbatus except posterior margin slightly more narrowly rounded; striae 1 moderately, others feebly impressed, punctures rather small, deep; interstriae smooth, shining, feebly convex, twice as wide as striae, sparsely, uniseriately punctured, except punctures on 1 replaced by granules or tubercles. Declivity as in perturbatus except spine 3 stouter, not capitate.

Male.- Similar to female except frons more evenly convex, feebly protuberant, surface with a few fine punctures above, a few fine granules on lower half; sparsely pubescent; declivital spines very slightly larger.

Distribution.- Alaska and Newfoundland to Montana, Minnesota, and Maine.

ALASKA: Ohmer Lake on Kenai Peninsula, Rampart House. CANADA: Alberta: Alexander Falls on McKenzie Highway, Banff, Canada Prairie, Cypress Hills, Edmonton, Kananaskis, Mitsue. Peace River below Cherry Point, Pidmondon, Smith, Wabamun. British Columbia: Kootenay Valley. Manitoba: Aweme, Clear Lake, Red Deer, Riding Mts., Winnipeg. New Brunswick: Halcomb, McGraw Brook, Plaster Rock, Riley Brook. Newfoundland: Pasadena, St. Antony, Northwest Territories: Aklavik, Great Bear Lake, Ft. Simpson, Ft. Smith, Reindeer Depot on McKenzie River Delta. Ontario: Hawk Junction, Lake Abitibi, Low Buck, Radiant, Smoky Falls on Mattagami River. Quebec: Gaspé Co., Godbout, Lake Opasatika, Mt. Albert, Rupert House. Saskatchewan: Big River, Canoe Lake, Prince Albert

Fig. 162. Ips borealis subspecies: 1, thomasi, male, 8, same, female; 2, 4-5, 7, horealis, male, 3, 6, same, femate; 9-10, swainei, male, 11, same, female. (After Hopping 1965:195.)
N.P. USA: Maine: Maine Agricultural Experiment Station. Minnesota: Itasca Park. Montana: Gillam.

Host. - Picea glauca.
Biology.- Essentially as in perturbatus.
Notes.- The above treatment was based on the lectotype and on 937 other specimens.

One female specimen from Ohmer Lake on Kenai Peninsula, Alaska, has fine pubescence on the epistoma. The significance of this hair could not be determined.

## 10. Ips borealis swainei R. Hopping

 Fig. 162Ips swainei R. Hopping, 1939, Canadian Ent. 71:169 (Holotype, female; Creighton Valley, Lumby, British Columbia; Canadian Nat. Coll.)
Diagnosis.- This subspecies is distinguished from $b$. borealis Swaine by the slightly more protuberant female frons, with rather dense, long pubescence on the lower half, and by the distribution.

Female.- Length 2.6-3.4 mm, 2.6 times as long as wide; as in $b$. borealis Swaine except for female frons.

Frons below upper level of eyes rather weakly to abruptly, rather strongly protuberant; this protuberance densely, deeply punctured (granules often present) and pubescent; vestiture moderately long, varying from rather sparse to dense.

Male.-As in male b. borealis or sometimes with larger frontal granules.

Distribution.- Creighton Valley and Trinity Valley, British Columbia.

CANADA: British Columbia: Lumby Creighton Valley, 18-VI-22, Picea engelmannii, R. Hopping; Trinity Valley, 6-VIII-54, P. engelmannii. J. M. Kinghorn; Vernon, VIl-22, R. Hopping.

Host.- Picea engelmannii.
Bıology.- As in b. borealis.
Notes.- The above treatment was based on the holotype and on 93 other specimens. This, presumably, is a geographically variable race of borealis. Some female specimens are indistinguishable from $b$. borealis except for the presence of a few punctures and setae on the lower frons. Other specimens in the same series exhibit the maximum expression of frontal protuberance and vestiture.

## 11. Ips borealis lanieri Wood

Ips borealis lanieri Wood, 1974, Brigham Young Univ. Sci. Bull. Ser. 19(I):27 (Holotype, female; 1 mile S Brownsville, Lawrence Co., South Dakota; Wood Coll.)

Diagnosis.- This subspecies differs from b. thomasi G. Hopping by the less strongly inflated lower female frons, with smaller granules and shorter, less abundant, finer vestiture, and by the distribution.

Female.- Length $3.0-3.8 \mathrm{~mm}, 2.6$ times as long as wide; as in $b$. borealis except for the female frons.

Frons as in $b$. borealis except much less strongly protuberant on lower half, entire frons with small, distinct punctures and, on lower half, a few fine granules; epistomal margin bearing a row of rather coarse granules. Frontal vestiture short, very sparse.

Male.-Similar to female except frontal punctures and granules much larger, more numerous.

Distribution.- Black Hills in South Dakota to Colorado.

USA: Colorado: 20 miles ( 32 km ) NW Pagosa Springs, Hinsdale Co., 28-V1-68. Picea engelmannii, S. L. Wood; Newcastle, V11-46, P. engelmannii, C. L. Massey. South Dakota: 2 miles ( 3 km ) SW Lead, 18-VI-68, P. glauca, S. L. Wood; Brownsville, 18-V1-68. P. glauca, S. L. Wood.

Hosts.- Picea engelmannii and $P$. glauca.
Biology.-As in b. borealis.
Notes.- The above treatment was based on 121 specimens, including the type series.

## 12. Ips borealis thomasi G. Hopping

 Fig. 162Ips thomasi G. Hopping, 1965, Canadian Ent. 97:193 (Holotype, female; Ingonish, Nova Scotia; Canadian Nat. Coll.)
Diagnosis.- This subspecies is distinguished from b. lanieri Wood by the more strongly inflated lower part of the female frons, with larger granules and much more abundant, longer, coarser vestiture, and by the distribution.

Female.- Length $3.2-3.6 \mathrm{~mm}, 2.5$ times as long as wide; as in b. lanieri except for frons.

Frons feebly to weakly protuberant on lower half, inflated area rather coarsely, closely granulate-punctate and pubescent; pubescence moderately to very abundant, long; epistoma bearing a row of moderately coarse tubercles.

Male.-Similar to female except lower frons feebly protuberant, more sparsely pubescent, granules less abundant, slightly larger.

Distribution.- Nova Scotia.
CANADA: Nova Scotia: Ingonish, 30-X-61, Picea glauca, J. B. Thomas.

Biology.- Presumably as in $b$. borealis.
Notes.- The above treatment was based on the holotype, on 24 paratypes, and on 26 other specimens.

## 13. Ips tridens tridens (Mannerheim) Fig. 163

Bostrichus tridens Manmerheim, 1852, Moskov. Olshch. Isp. Prirody, Otd. Biol. Biul. (Bull. Soc. Imp. Nat. Moscou) 25:357 (reprint p. 75) (Lectotype, female; Sitka Island, Alaska; Univ. Zool. Mus., Helsinki, present designation)
Bostrichus interruptus Mannerheim, 1852, Moskov. Obslach. Isp. Prirody, Otd. Biol. Biul. (Bull. Soc. Imp. Nat. Moscou) 25:357 (reprint p. 75) (Lectotype, female; Sitka Island, Alaska; Univ. Zool. Mus., Helsinki, present designation); Wood, 1969. Great Basin Nat. 29:115. Synonymy
Diagnosis.- This species is distinguished from borealis Swaine by the larger size and by the more strongly granulate female frons. This subspecies is distinguished from $t$. engelmanni Swaine by the feebly protuberant female frons, which is almost as coarsely granulate and as sparsely pubescent as in the male.

Female. - Length $3.8-4.3 \mathrm{~mm}, 2.5$ times as long as wide; color dark brown to almost black.

Frons convex, feebly protuberant below upper level of eyes, contour of upper area somewhat irregular; surface shining, rather densely, rather finely granulate with few, fine punctures interspersed below, granules largely replaced by punctures toward vertex; epistomal margin with a row of coarse granules; vestiture of rather sparse, fine, long hair.

Pronotum 1.15 times as long as wide; as in b. borealis except punctures in posterior areas averaging smaller, slightly closer.

Elytra 1.5 times as long as wide; as in $b$. borealis except strial punctures smaller, interstriae almost three times as wide as striae.

Male.-Similar to female except lower frons less distinctly protuberant, granules larger, particularly those on epistomal margin; declivital spines very slightly larger.

Distribution.- Coastal area from Alaska to N California.

ALASKA: Seward, Sitka Island. CANADA: British Columbia: Agassiz, Mission Inn, Revelstoke Mts., Vancouver. USA: California: Crescent City, Del Norte. Oregon: Astoria, Branden, Clatsop, Hebo, Jackson, Marshfield, New Denmark. Washington: Hoquiam, Kent, Spokane.

Hosts.- Picea sitchensis, a few records from $P$. glauca in Alaska.

Biology. - Basically as in perturbatus (Eichhoff) except egg galleries usually longer, with parallel galleries closer together.

Notes.- Five specimens are in the Mannerheim collection under the name Bostrichus tridens Ménétriés. Three of these, all from Sitka, are with other type material and consist of (1) a female taken by Pippingsköld, and (2 and 3) two males taken by Holmberg. The other two specimens are with duplicates and unsorted material and consist of (1) a female $t$. engelmanni from Sitka without the name of the collector, and (2) a specimen of pini (Say) from another location and received from Chapius. The female from Sitka taken by Pippingsköld bears Mannerheim's label and is here designated as the lectotype of $t r i$ dens. Five specimens of Bostrichus interruptus Mannerheim are in the Mannerheim collection from Sitka; only one was taken by Frankenhaeuser and bears a type label; it is marked as a male, but is actually a female, and it is here designated as the lectotype of interruptus. The female lectotypes of tridens and interruptus were compared directly to one another and to my female from Oregon. The above treatment was based on my homotype and on 194 other specimens.

## 14. Ips tridens engelmanni Swaine <br> Figs. 163-164

Ips engelmanni Swaine, 1917, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(1):30 (Lectotype, female; Rogers Pass, British Columbia; Canadian Nat. Coll., 9308 , designated by Bright, 1967, Canadian Ent. 99:675)
Ips yohoensis Swaine, 1917, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(1):31 (Lectotype, female; Yoho Valley, British Cotumbia; Canadian Nat. Coll., 9309, designated by Bright, 1967, Canadian Ent. 99:676); Wood, 1977, Great Basin Nat. 37:396. Synonymy
Ips dubius Swaine, 1918, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(2):119 (Holotype, male; Rogers Pass, British Columbia; Canadian Nat. Coll.); Wood, 1957, Canadian Ent. 89:397. Synonymy
Ips semirostris G. Hopping, 1963, Canadian Ent. 95:213 (Holotype, female; Kenai Peninsula, Alaska; Canadian Nat. Coll.); Wood, 1977, Great Basin Nat. 37:386. Synonymy
Ips amiskwiensis G. Hopping, 1963, Canadian Ent. 95:2I6 (Holotype, female; Amiskwi River, Yoho Nat. Pk., British Columbia; Canadian Nat. Coll.); Wood, 1977, Great Basin Nat. 37:386. Synonymy

Fig. 163. Ips spp.: 7-8, tridens engelmanni, male, 10-11, same, female; 9, tridens tridens, female; 12-13, pilifrons sulcifrons, female; 14, pilifrons pilifrons, female. (After Hopping 1965:163.)

Diagnosis.- This subspecies is distinguished from $t$. tridens (Mannerheim) by the moderately to profoundly protuberant female frons, with frontal vestiture varying from glabrous to densely pilose and from minute pile to long hair.
Female.- Length 3.3-4.3 mm, 2.5 times as long as wide; as in $t$. tridens (Mannerheim) except for frons.

Frons below upper level of eyes varying from moderately to abruptly, profoundly protuberant, protuberance granulate to rugose, glabrous to pilose; vestiture, when present, varying from minute to long and very abundant. Epistomal tubercles minute or obsolete (highly variable within or between series).
Male--Similar to female except frons as in t. tridens male.

Distribution.- Alaska and Northwest Territories to N California and NW Wyoming.

ALASKA: Echo Cove, Fick Cove at Chichagoff Isl., Hollis, Juneau, Kenai Peninsula, Lastrum, McKinley N.P., Rogers Point, Seward, Sheenjek, Sitka Island. CANADA: Alberta: Banff, Blairmore, Carbondale Road near Crowsnest, Exshaw. British Columbia: Barkerville, Emerald Lake, Glacier, Kooteney, Limberton, Marble Canyon, Nahun, Nicola, Quesnel, Queens Lake, Pine Pass, Stanley, Terrace, Trinity Valley, Two Sisters Mt., Vermillion, Yoho N.P. Northwest Territories: Aklavik. Yukon: Otter Lake, Rancheria, Swim Lakes. USA: Califormia: Callahan in Siskiyou Co. Idaho: Coeur d'Alene, Krassel, Lakeview. Montana: Banfield, Cable Creek at Libby, Cedar Lake in Lake Co., Columbia Falls, Eureka, Glacier N.P. Oregon: Dixie Pass, Gold Lake in Willamette N.F., Suttle Lake, Tollgate. Washington: Parkway. Wyoming: Yellowstone N.P.
Hosts. - Picea glanca, P. engelmamnii, and, in Alaska, P. sitchensis.

Biology.-As in t. tridens. Lanier (1966) reported partial gynogenetic parthenogenesis and abnormal sex ratios in this subspecies.

Notes.- The type series of engelmanni, dubius,o and yohoensis and the holotypes of amiskwiensis and semirostris were examined, as well as 580 other specimens.

The female frons of this subspecies varies radically in protuberance and in vestiture. This variability, coupled with partial parthenogenesis, has produced anatomically uniform local populations adjacent to uniform local populations of other very different anatomical forms. It is also possible to find three or more anatomically different forms of females in the same parental gallery system
with one male, or in the brood of a single female. It must be concluded, therefore, that the female frons in this subspecies is genetically unstable and can take a wide variety of forms unrelated to geographical origin or host relationships.

## 15. Ips pilifrons pilifrons Swaine Figs. 163, 164

Ips pilifrons Swaine, 1912, Canadian Ent. 46:353 (Holotype, female: Colorado; Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from $t$. tridens (Mannerheim) by the larger size, by the larger, deeper strial punctures and proportionately narrower interstriae, by the different modifications of the female frons, and by the distribution. From p. sulcilfrons Wood it is distinguished by the sculpture of the female frons.

Female.- Length $4.4-5.0 \mathrm{~mm}, 2.5$ times as long as wide; color very dark brown.

Frons as in $t$. tridens except contour of vertex more regular, more sharply punctured; area below upper level of eyes feebly to moderately protuberant, granules much more numerous, particularly in lateral areas; row of epistomal tubercles present at least laterally; vestiture of dense, minute velvetlike pile with no long hair. (Intergrades between $p$. pilifrons and $p$. utahensis often with a combination of pile and long hair.)

Pronotum as in $t$. tridens except punctures in posterior areas averaging slightly larger.

Elytra 1.5 times as long as wide; as in $t$. tridens except striae more distinctly impressed, punctures larger, interstriae one to almost two times as wide as striae, rarely with minute impressed points; declivity slightly more deeply concave, lateral margins slightly more strongly elevated (distinctly more than in $t$. engelmanni), spine 3 longer, distinctly capitate.

Male.-Similar to female except frons as in male $t$. tridens but surface much more rugose in addition to granules; declivital spines slightly larger, 3 capitate with apex subacute.

Distribution.- North central Colorado and adjacent Wyoming.

USA: Colorado: Craig, Glenwood Springs, Rabbit Ears Pass; those from Pingree Park and Redfeather Lakes more or less intergrade with $p$. utahensis. Wyoming: Snowy Range west of Laramie.

Host.- Picea engelmannii.

Fig. 164. Ips spp., dorsal and lateral aspects of declivity: 15, 18-19, tridens engelmanni, female, 16, same, male; 17, pilifrons sulcifrons, male; 20, pilifrons pilifrons, male. (After Hopping 1965:165.)

Biology.- As in $t$. tridens.
Notes. - The above treatment was based on the holotype of pilifrons and on 61 other specimens. Specimens of this species from Wyoming, the eastern part of the Uinta Mountains in Utah, and from northwestern Colorado are assigned to $p$. utahensis although intergradation with $p$. pilifrons is apparent. Females from these areas may have a certain amount of dense frontal pubescence, but the pile is usually considerably longer, particularly at the margins, than is seen in specimens from Rabbit Ears Pass, Colorado. A population with similar minute velvetlike pile on the female frons, from Mount Wheeler, Nevada, has other frontal characters that were used to define the subspecies $p$. thatcheri.

## 16. Ips pilifrons sulcifrons Wood

Figs. 163-164
Ips sulcifrons Wood, 1960, Great Basin Nat. 20:67 (Holotype, female: Santa Fe Ski Basin, New Mexico; California Academy of Sciences)
Diagnosis.- This subspecies is distinguished from $p$. pilosus Swaine by the strongly protuberant female frons, which is deeply, narrowly sulcate, with the sides of the sulcus varying from glabrous to densely, minutely pubescent.

Female.- Length 4.4-5.0 mm, 2.6 times as long as wide; as in $p$. pilifrons except for female frons.

Frons rather strongly to profoundly protuberant below uppper level of eyes, protuberance deeply divided by an abrupt median sulcus; surfaces (exclusive of sulcus) smooth, shining, finely, rather closely punctured, most of punctures on protuberance accompanied by a minute granule; surfaces of sulcus rather finely granulose, either glabrous (rare) or densely covered by minute velvetlike pile.

Male.- Apparently indistinguishable from male $p$. pilifrons.

Distribution.-SW Colorado to New Mexico.

USA: Colorado: 20 miles ( 32 km ) SW Del Norte, 26-VI-68, Picea engelmannii, W. G. Harwood. New Mexico: Coyote: 23-VIII-67, P. engelmannii, C. J. Germain; Pocos, 18-1X-67, P. engelmannii, C. J. Germain; Santa Fe Ski Basin, 13-VIII-62, P. pungens, P. engelmannii, S. L. Wood; near Santa Fe, 6-X-49, O. Bryant; Sandia Mts., 30-V-69, P. engelmannii, S. L. Wood.

Hosts.- Picea engelmannii, P. pungens.
Biology.-As in t. tridens.
Notes.- The above treatment was based on 11 paratypes, on 71 topotypes, and on 43 other specimens.

This is apparently a distinct geographical race of pilifrons; however, I have seen no intergrades or indications of sympatry. Hopping (1965:166) reports specimens from Cedar Breaks Nat. Mon. and Beaver, Utah, but my examination of those specimens indicates they are of $p$. utahensis. It appears that $p$. pilifrons and $p$. sulcifrons arose simultaneously from $p$. utahensis from a stock that then became subdivided through isolation.

## 17. Ips pilifrons utahensis Wood Fig. 161

Ips utahensis Wood, 1960, Great Basin Nat. $20: 66$ (Holotype, female: Logan Canyon, Utah; Wood Coll.)
Diagnosis.- This subspecies is distinguished from other subspecies of pilifrons by the very weakly protuberant, much more strongly granulate, more sparsely pubescent female frons. The pilosity of the female frons tends to integrate somewhat on the margins of $p$. pilifrons distribution.

Female.- Length $4.4-5.0 \mathrm{~mm}, 2.5$ times as long as wide; color very dark brown.

Frons on lower half only slightly more inflated than in male, granulation almost as coarse and dense as in male; vestiture usually only slightly more abundant in male, fine, long, a small amount of short pilose pubescence often present at margins of $p$. pilifrons distribution, but setae at margins of pilose area much longer than in $p$. pilifrons.

Pronotum and elytra as in $p$. pilifrons.
Male.-As in p. pilifrons male.
Distribution.- Wyoming and W Colorado to N Arizona.

USA: Arizona: Grand Canyon N.P., Kaibab N.F., San Francisco Mts. Colorado: Boulder, Cochetopa, Gould, Holy Cross N.F., Leadville, Los Pinos Pass in Saguache Co., Montezuma N.F., Newcastle, Pagosa Springs in Hinsdale Co., Pingree Park, Steamboat Springs. Idaho: Franklin Basin Road in Franklin Co., Viola. Utah: Alta, Ashley N.F., Beaver, Dixie N.F., Fishlake N.F., La Sal Mts., Logan Canyon, Mammoth Mit., Monte Cristo, Monticello, Park City, Spirit Lake in Uinta Mts., Wolf Creek Pass. Wyoming: Buffalo, Hayden, Saratoga.

Host.- Picea engelmannii.
Biology.-As in p. pilifrons.
Notes.- The above treatment was based on the holotype and on 661 other specimens.

In the east central part of its range this subspecies tends to intergrade with $p$. pilifrons. It appears that $p$. utahensis is the parental population that gave rise to all of the other subspecies of pilifrons.
18. Ips pilifrons thatcheri Wood

Ips pilifrons thatcheri Wood, 1975. Great Basin Nat. 35:29 (Holotype, female: Mt. Wheeler, Nevada: Wood Coll.)
Diagnosis.- This subspecies is distinguished from $p$. pilifrons Swaine by characters of the female frons as indicated below. The comparisons are based on females having the maximum expression of frontal characters.

Female.- Length $3.9-4.9 \mathrm{~mm}, 2.5$ times as long as wide; color very dark brown.

Frons similar to $p$. pilifrons except less strongly, less extensively elevated, elevation occupving lower 80 percent of median distance from epistoma to upper level of eyes (115 percent in $p$. pilifrons) and pubescent area occupying less than 50 percent of median area between eyes ( 80 percent in $p$. pilifrons); lateral areas much more sparsely, more finely granulate than in $p$. pilifrons. Pronotum, elytra, and other features essentially as in $p$. pilifrons.

Male.-Similar to male $p$. pilifrons except frontal vestiture less abundant and shorter, particularly along epistoma.

Distribution.- Mt. Wheeler, Nevada.
USA: Nevada: Mt. Wheeler at Baker Creek, 8-VIII-38, Picea engelmamii, T. O. Thatcher; Mt. Wheeler, 10-VIII-74, $10,000 \mathrm{ft}$ elevation, $P$. engelmannii, S. L. Wood.

Host.- Picea engelmannii.
Bıology.-As in p. pilifrons.
Notes. - The above treatment was based on the type series of 50 specimens and on 3 other specimens.

## 19. Ips avulsus (Eichhoff)

Fig. 165
Tomicus aculsus Eichhoff, 1868, Berliner Ent. Zeitschr. 11:402 (Syntypes?: Amerique boreali; presumably lost with Hamburg Mus.)
Diagnosis.- This species is distinguished from the allied pini (Say) and bonanseai (Hopkins) by the smaller size, by the poorly developed, subacute ventrolateral margin of the elytral declivity, by the wider striae and proportionately narrower interstriae, and by
the smaller, noncapitate spine 3 on the male declivity.

Male.- Length 2.1-2.8 mm, 2.6 times as long as wide; color rather dark reddish brown.

Frons broadly convex, rather weakly, transversely impressed above epistoma; surface shining, coarsely, deeply, closely punctured, with a few granules intermixed, a large, rounded, median tubercle just below center; epistoma with a row of coarse granules; vestiture of sparse hair. Sutures of antennal club moderately bisinuate.

Pronotum 1.2 times as long as wide; sides almost straight and parallel on posterior twothirds, rather broadly rounded in front; summit in front of middle; anterior slope rather coarsely asperate; posterior area smooth, shining, punctures rather coarse, deep, moderately close. Discal area glabrous, sides and asperate area with rather sparse, moderately long hair.

Elytra 1.4 times as long as wide; outline as in perturbatus (Eichhoff); striae 1 slightly, others not impressed, punctures rather coarse, deep, smaller near base and near declivity; interstriae as wide as striae, smooth, shining, impunctate except two or three punctures on each near declivity. Declivity about as in female perturbatus; lateral margins armed by four spines as in perturbatus, but smaller, spines 2 and 3 with a moderately developed basal connection; subapical margin subacute, less strongly elevated than in related species.

Female.- Similar to male except basal connection between spines 2 and 3 more poorly developed.

Distribution.- Wisconsin and New Jersey to E Texas and Florida.

USA: Alabama: Mobile. Arkansas: DeQueen. District of Columbia: Washington. Florida: Baldwin, Dade Co., Gainesville, Lake Co., LaBelle. Oleno St. Pk., Orlando, Tampa. Georgia: Cornelia, Clarke Co., Everett, Rebun. Tybee. Louisiana: Bogalusa. Mississippi: Hattiesburg. New Jersey: Trenton. North Carolina: Ashville, Broadman, Flat Rock, Horse Cove, Pink Beds, Southern Pines, Tryon. Pennsylvania: Arendtsville, Chambersburg, Mt. Alto, North ift., Philadelphia, York. South Carolina: Chicora, Greenville, Lumber, Spartinsburg. Texas: Call, Karnack, Kirbyville, Nacogdoches, Sourlake. Virginia: Camp Pickett in Nottoway Co., Richardsville. West Virginia: Kanawha Station, Morgantown, Pendleton, Roosevelt. Wisconsin: Madison. OTHER AREAS: Bahama 1slands.

Fig. 165. Ips spp.: 1, 3, arulsus, male, 2, same, female; 4, bonanseai, female, 5-6, same, male; 7, pini, female, 8-9, same, male; 10, perroti, female, 11-12, same, male. (After Hopping 1964:973.)

Hosts. - Pinus spp.
Biology. - As in pini.
Notes. - The above treatment was based on 528 specimens, including the specimens of LeConte and Schwarz, some of which may have been examined by Eichhoff. This species is easily identified from the original description. Eichhoff (1878:256) gives Carolina as the type locality.

## 20. Ips bonanseai (Hopkins)

 Fig. 165Tomicus bonanseai Hopkins, 1905, Preprint of Proc. Ent. Soc. Washington 7:76 (Lectotype, male; Tacubava. Mexico; U.S. Nat. Mus., 7514 , present designation)
Diagnosis.- This species is distinguished from pini (Say) by the smaller size, by the differences in pronotal punctures cited in the above key, by the distribution, and by the larger frontal tubercle, which is connected by a low costa to a smaller epistomal tubercle.
Male.- Length 2.9-3.4 mm, 2.5 times as long as wide; color very dark reddish brown.
Frons essentially as in pini except frontal granules less abundant, larger but lower, fewer than one-fourth of them above upper level of eyes; median tubercle distinctly larger, and connected by a weak costa to a slightly smaller median tubercle on epistoma.
Pronotum as in pini except punctures on disc and lateral areas about equal in size. Elytra as in pini except strial punctures evidently average very slightly larger.
Female.- Similar to male except declivital spines slightly smaller, 3 usually not capitate.

Distribution.-S Arizona to Honduras.
USA: Arizona: Graham Mts., Pima Co., Pinaleno, Portal, Rustler Peak in Chiricahua Mts., Safford, Santa Catalina Mts., Santa Rita Mts. MEXICO: Chiapas: San Cristóbal. Distrito Federal: Mexico City. Durango: El Salto, La Ciudad. Hidalgo: Tulancingo. Jalisco: El Tala. Mexico: Amecameca. Michoacán: Bosenchene. Puebla: Texmelucan. Temescaltepec: Real de Arriba. Veracruz: Las Vigas. GUATEMALA: Guatemala. HONDURAS: Buenos Aires in Cortéz.
Hosts.- Pinus montezumae, P. ponderosa, P. pseudostrobus, P. spp.

Bology.- Evidently as in pini, but found more commonly in limbs.

Notes. - The above treatment was based on the holotype of bonanseai and on 964 other specimens. Hopkins based this species on a syntypic male and female. Although his
male is in poor condition, its characters are more diagnostic; therefore, I here designate that male as the lectotype of bonanseai.

## 21. Ips pini (Say)

Figs. 165, 166
Bostrichus pini Say, 1826, J. Acad. Nat. Sci. Philadelphia 5:257 Syntypes?: probably Pennsylvania; evidently lost)
Bostrichus dentatus Sturm, 1826, Catalog meiner $\mathrm{I}_{11}$ -secten-Sammlung, Erster Theil, Käfer, p. 76 (Amer. Bor.); Eggers. 1931. Wiener Ent. Zeit. 47:185. Synonymy
Bostrichus pallipes Sturm, 1826, Catalog meiner ln-secten-Sammulung, Erster Theil, Käfer, p. 76 (apparently as nomen nudum); Eggers, 1931, W'iener Ent. Zeit. 47:185. Synonymy
Tomicus pracfrictus Eichhoff, 1868, Berliner Ent. Zeitschr. 11:401 (Syntypes?: Amerique boreali; presumably lost with Hamburg Mus.); Eichhoff, 1878, Mém. Soc. Roy. Sci. Liége (2)8:252. Synonymy
Tomicus oreqonis Eichhoff, 1869, Berliner Ent. Zeitschr. 12:274(Holotype, male; Oregon; Brussels Mus.); Hopping, 1964, Canadian Ent. 96:97.4. Synonymy Tomicus rectus LeConte, 1876, Proc. Amer. Philos. Soc. 15:365 (Lectotype, female; Oregon, only a blue paper disk on lectotype; Mus. Comp. Zool., 1023. present designation); Swaine, 1918, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. $14(2): 117$. Synonymy
Ips laticollis Swaine, 1918, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(2):116 (Lectotype, male; Ottawa. Ontario, Canada; Canadian Nat. Coll., 9303, designated By Bright. 1967, Canadian Ent. 99:675); Wood, 1957, Canadian Ent. 89:398. Synonymy
Diagnosis.- This species is distinguished from the very closely related bonanseai (Hopkins) by characters summarized in the above key and in the diagnosis of bonanseai.
Male.- Length $3.3-4.3 \mathrm{~mm}, 2.5$ times as long as wide; color dark reddish brown to almost black.

Frons broadly convex, moderately, narrowly, transversely impressed above epistoma; surface shining, irregular, rather coarsely, deeply, closely punctured on vertex, intermixed with and gradually replaced by rather coarse, rounded granules toward epistoma, at least a third of granules above upper level of eyes; a moderately large major tubercle on median line midway between upper level of eyes and epistoma; epistomal margin with a row of rather coarse tubercles, without a major tubercle on median line; vestiture of sparse, fine, long hair. Sutures of antennal club moderately bisinuate.

Pronotum 1.1 times as long as wide: essentially as in aculsus except punctures in discal area slightly smaller, those near lateral margins slightly larger.

Elytra 1.7 times as long as wide; as in perturbatus except striae 1 weakly, others not impressed; interstriae smooth, shining, impunctate, usually each with one or two punctures near declivital margin; four spines on lateral margins as in perturbatus except apex of spine 3 bent slightly ventrad.

Female.- Similar to male except major frontal tubercle slightly smaller; declivital spines slightly smaller, particularly 3 , spine 3 usually not capitate.

Distribution.- Alaska and Newfoundland to Chihuahua and North Carolina.

ALASKA: Two localities at sonthem tip. CANADA: Alferta. British Cohmbia, Manitota, New Brmowick. Newfoundland, Nova Scotia, Ontario, Quebec, Saskatchewan, Sukon. USS: Arizona, Califormia, Colorado. Connecticnt, District of Columbia, Idaho, Maine, Mas sachusetts, Michigan, Minnerota, Montana, Nehraska Nevada, New Hamphire, New Mexico, New York. North Carolina, Ohio, Oregon, Penustvania, Rhode Island, South Dakota, Utah, Vermont, Washington. West

Virginia, Wisconsin, Wroming. MEXICO: Chihuahua: La Laja.

Hosts.- Pinus banksiana, P. contorta, P. ieffreyi, P. ponderosa, P. strobus, rarely in other hosts.

Biology.- Unthrifty, fallen, or eut trees and large limbs are selected for attack. It frequently infests the tops and larger limbs of trees being attacked by Dendroctonus and thereby may accelerate and intensify an epidemic. They rarely are able to sustain a primary attack without the association of Dendroctonus. The parental galleries are Yshaped and longitudinal, usually with three females associated with each male. The egg galleries are comparatively long. From three to four generations may be completed each year.

Notes. - The above treatment was based on the type series of rectus and laticollis, on the LeConte series of pini, on the holotype of oregonis, and on 3,834 other specimens. The identity of pini was established by LeConte from notes and specimens of T. W. Harris, who saw Say's types. Based on specimens sent

Fig. 166. Ips spp., galleries: 13, pini; 14. perroti. (After Hopping 1964:975.)
by LeConte, Eichhoff placed his praefectus in synonymy. The first specimen of rectus now in the LeConte collection and labeled Type No. 1023, is here designated as the lectotype of rectus LeConte.

## 22. Ips integer (Eichhoff)

Figs. 167. 165

Tomicus integer Eichhoff, I869, Berliner Ent. Zeitschr. 12:27.3 (Syntypes?; Mexico; presumably lost with Hamburg Mus.)
Diagnosis.- This species is distinguished from plastographus (LeConte) by the larger average size, by the carinate ridge connecting the major median frontal tubercle to the epistomal margin, and by other characters summarized in the above key.

Male.- Length 4.6-5.7 mm, 2.6 times as long as wide; color brown to almost black.

Frons convex, with a weak, transverse impression above epistoma; surface shining, coarsely, closely granulate from epistoma to vertex, punctures almost obsolete except on vertex; a coarse major median tubercle intermediate in position between epistoma and upper level of eyes connected by an elevated costa to another smaller major tubercle on epistoma; epistoma with a transverse row of coarse tubercles. Vestiture fine, sparse, long. Antennal club with sutures 1 and 2 acutely angulate.

Pronotum 1.1 times as long as wide; as in perturbatus except punctures on posterior half moderately coarse, close, rather deep, those on posterior part of dise decreasing in size until rather small near posterior margin.

Elytra 1.5 times as long as wide; outline essentially as in perturbatus; striae 1 slightly, others not impressed, punctures moderately coarse, rather deep; interstriae smooth, shining, one to one and one-half times as wide as striae, impunctate at least on anterior twothirds, fine, uniseriate punctures near declivity, sometimes extending almost to middle of disc. Declivity basically as in perturbatus, with spine 3 larger, capitate, apex usually not bent. Vestiture as in perturbatus.

Female.- Similar to male except major tubercles on frons slightly smaller; declivital spine 3 smaller, not capitate.

Distribution.- British Columbia and South Dakota to Guatemala (eastern slopes
only of the Sierra Nevada Mountains in California).

CANADA: British Columbia: Armstrong, Beaverdell, Canal Flats, Coldwater Creek. Cottrell. Jerome. Kimberley, Lorna, Lumby in Creighton Valley, Merritt in Midday Valley. Nicola, Oliver, Peachland, Princeton, Skookumehuck, Summerland, Vernon, Wasa, Westwold. U'SA: Arizona: Alpine in Greenlee Co., Chiricahua Mts.. Flagstaff, Ft. Valley, Globe, Gila N.F., Grand Canyon. Jerome, Kaibab N.F., Kendrick Mt., Lake Mary, Mormon Lake. Mt. Lemon, Paradise, Portal. Prescott, Safford, San Francisco Mts., Santa Catalina Mts., Springvale, White Mt.. Williams. California: Alpine Co., Antelope Creek in Siskiyou Co., Clio in Plumas Co.. Downieville in Sierra Co., Norval Flats and Poison Lake in Lassen Co. Colorado: Bailey, Boulder, Colorado N.F., Fish Creek in Montezuma Co.. Hustead, Larkspur, Montezuma N.F., Norwood, Pagosa Springs, Pingree N.P.. San Isobelle N.F., Trichere, Waldo Canyon, Woodland Park. Idaho: Cascade, Centerville, Coeur d'Alene, Cragmont, Moscow, Nezperce, Orofino, St. Joseph N.F., Smiths Ferry. Montana: Bull Mts., Darby, Drummond. Havre, Pine Grove, Rocky Boy Indian Reservation in Hill Co., Warland. New Mexico: Capitan. Cloudcroft, Jemez Springs, Las Vegas, Lincoln N.F., Mescalero Indian Reservation. Parsons. Ruidoso. Sacramento Mts.. Santa Fe, Vermejo. Oregon: Baker, Bend, Dallas, Grant Co., Hidaway, Jackson Co., Kirk. Sparta, Summit Prairie, Willowa. South Dakota: Harney. Utah: Long Hollow in Dixie N.F., Long Valley Junction, Navajo Mit., Panguitch. Washington: Buckeye, Mt. Adams, Palouse, Soda Falls, Spokane, Yakima, MEXICO: Chihuahua: La Laja, Mesa del Huracán. Durango: Buenos Aires, El Salto. Hidalgo: Tulancingo. Jalisco: Mt. Colima, Mazamitla. Mexico: Laguna de Zempodla. Michoacán: Carapan. Puebla: Texmelucan. Tlaxcala: Desierto Leones. Veracruz: Las Vigas, Perote. Zacatecas: "El Gardo," Valparaíso. GUATEMALA: San Cristóbal, Sololá.

Hosts. - Pinus arizonica, P. chihuahuana, P. cooperi, $P$. durangensis, $P$. engelmannii, $P$. leiophylla, P. patula, P. ponderosa, P. pseudostrobus, and P. tenuifolia; rarely P. contorta and other conifers.

Biology.- Thick barked fallen trees or logs are usually selected for attack. From one to five elongate, longitudinal egg galleries are associated with each nuptial chamber. Larval mines are moderately long. Young adults do not tunnel into the wood at or near the pupal cells as in plastographus.

Notes- The above treatment was based on 1,276 specimens. The identity of this species was based on the series of Chapuis, LeConte, Hopkins, Swaine, Blackman, and Eggers.

## 23. Ips plastographus plastographus (LeConte) <br> Fig. 160

Tomicus plastographus LeConte, 1868, Trans. Amer. Ent. Soc. 2:163 (Holotype, male; California; Mus. Comp. Zool., I016)
Ips plastographus plastographus: Lanier, 1970, Canadian Ent. 102:1415
Diagnosis.- This species is distinguished from integer (Eichhoff) by the smaller average size, by the absence of a connecting carina from the major median frontal tubercle to the epistomal margin, and by the smaller, circular strial punctures. From p. maritimus Lanier it differs by the larger major frontal tubercle and by other minor characters included in the above key.

Male.- Length $4.0-5.2 \mathrm{~mm}, 2.6$ times as long as wide; as in integer except as noted in diagnosis and below.

Major median frontal and epistomal tubercles smaller, not connected by an elevated costa; sutures of antennal club angled at about 90 degrees, not acute; strial punctures smaller than in integer, interstriae one and one-half to two times as wide as striae.

Female.-Similar to male except major frontal tubercles smaller; declivital spine 3 distinctly smaller, usually not capitate.

Distribution.-S British Columbia and NE Wyoming to central California.

CANADA: British Columbia: Cranbrook. USA: California: Numerous localities in the following counties (Lanier 1970): Alpine, El Dorado, Fresno, Lassen, Madera, Mariposa, Mono, Nevada, Placer, Plumas, Riverside, San Bernardino, Shasta, Siskiyou, Trinity, Tulare, Tuolumne. Idaho: Targhee Pass in Fremont Co. Oregon: Crater Lake, Diamond Lake in Douglas Co., Fly Creek in Union Co., Florence, Lake of the Woods in Klamath Co., Sand Lake in Siuslaw N.F., Warner Mits. Montana: Drummond, Missoula N.F., Parsnip Mt. in Lincoln Co., Georgetown Lake in Deer Lodge Co., Whitefish in Flathead Co. Wyoming: Old Faithful in Yellowstone N.P., Shoshone N.F.

Host.-Pinus contorta, rarely in $P$. ponderosa.

Biology.- The upper side of fallen or cut logs is usually selected for attack. Two or three longitudinal egg galleries extend from each nuptial chamber. When two egg tunnels extend in the same direction, they are parallel and less than 5 cm apart. Larval mines wander irregularly; young adults have the unusual habit of boring into the wood to a depth of about 1 cm (Lanier 1967).

Notes. - The above treatment was based on the male holotype and on 176 other specimens.

## 24. Ips plastographus maritimus Lanier

Ips plastographus maritimus Lanier, 1970, Canadian Ent. 102:1417 (Holotype, female; Rio del Mar, Santa Cruz Co., California; Canadian Nat. Coll.)
Diagnosis. - This subspecies is distinguished from p. plastographus (LeConte) by the near absence of the major median frontal tubercle, and by other minor characters included in the above key.

Male.- Length $4.0-5.1 \mathrm{~mm}, 2.6$ times as long as wide; as in $p$. plastographus except for the smaller major frontal tubercles, more widely spaced striations on the pars stridens, and proportionately shorter struts on the male aedeagus.

Female.- Apparently similar to male except declivital spine 3 smaller.

Distribution.- The coastal margin of Oregon and California.

USA: California: Carmel, Cambria Pines in San Luis Obispo Co., Crescent City, Del Monte, Ft. Brag, Inverness, Myers Flat, Monterev, Oakland, Pacific Grove, Palo Alto, Rio del Mar, San Mateo. Oregon: Seaside, Tillamook.

Hosts.- Pinus contorta, P. muricata, P. radiata, one authentic record from Picea sitchensis.

Biology.-Apparently as in $p$. plastographus.

Notes. - The above treatment was based on the holotype and on 87 other specimens. This is not a well-marked subspecies and its validity is very doubtful.
25. Ips emarginatus (LeConte)

Figs. 167, 168
Tomicus emarginatus LeConte, 1876, Proc. Amer. Philos. Soc. 15:364 (Lectotype, female; Oregon; Mus. Comp. Zool., 1024, present designation)
Diagnosis.- This very large and distinctive species is easily recognized by characters summarized in the above key.

Male.-Length 5.5-6.9 mm, 2.8 times as long as wide; color very dark brown.

Frons broadly convex, a slight impression above epistoma; surface shining, coarsely, closely granulate from epistoma to well above eyes, granules gradually replaced by punctures toward vertex; epistoma with a

Fig. 167. Ips spp.: 1-2, emarginatus, male, 3, same, female; 4-5, knausi, male, 6, same, female; 7-8, integer, male, 9, same, female. (After Hopping 1963:1204.)
row of granules a major rounded tubercle on median line. Vestiture fine, long, sparse.

Pronotum 1.1 times as long as wide; outline essentially as in perturbatus; posterior areas smooth, shining, punctures rather large, close, deep.

Elytra 1.6 times as long as wide; outline essentially as in perturbatus except posterior margin obtusely subangulate; striae 1 moderately, others weakly impressed, punctures rather small, deep, close; interstriae twice as wide as striae, smooth, shining, impunctate except near declivity. Declivity broadly, deeply excavated, much as in allied species; spine 1 rather small, in line with striae 2 ; spine 2 conspicuously larger than 1, in line with striae 3 ; spine 3 enlarged, laterally compressed, apically emarginate, longer than 2 ; spine 4 usually obsolete although occasionally present in rudimentary form; subapical margin strongly produced, its summit undulating slightly; surface of declivital face dull. Vestiture confined to sides, base, and margins of declivity.

Female.- Similar to male except declivital spine 3 somewhat smaller.

Distribution.- S British Columbia and E Montana to Baja California.
CANADA: British Columbia: Appen Grove, Merritt in Midday Vatley, Kingsvale, Spious Creek, Summerlind, Vanconver. U'S: California: Numerous records from the following counties: Alpine, Calaveras, El Dorado, Glemn. Humboldt. Kern, Lassen, Los Angeles, Madera. Mariposa, Modoc. Mono, Nevada, Placer, Plumas, San Bernardino, Shasta, Siskiyou, Trinity, Tulare, Tuolumne. Idaho: Boise, Cascade, Centerville, Idaho City, Kooskia, Moscow, Priest River, Smiths Ferry, Troy, Warm Lake. Montana: Columbia Falls, Flathead Lake, Hamilton, Kila (Sedan), Nelson, Pine Grove, St. Regis, Sula. Oregon: Ashland, Baker. Cold Springs, Ft. Rock, Grant Co.. Grants Pass, Hidaway. Joseph, Klamath Co., Minam N.F., Sisters, Watlo Nit. in Baker Co. Washington: Columbia Co. MEXICO: Baja California: San Pedro Martín Mit.

Hosts.-Pinus ieffreyi, P. monticola, P. ponderosa, less common in P. contorta, and rare in other conifers.

Biology. - The base and stumps of mature, dying, or cut trees are usually selected for attack. The egg galleries are longitudinal, parallel, and may extend more than 1 m from the nuptial chamber. They may be connected by transverse tunnels. Larval mines are short, with pupation occurring close to the egg gallery. Chamberlin (1958) indicates that a

Fig. I68. Ips spp., galleries: 10, emarginatus; 11, integer, (After Hopping 1963:1205.)
generation may be completed in about 10 weeks.

Notes.- The one female remaining in the LeConte collection, labeled Type No. 1024, is here designated as the lectotype of emarginatus LeConte. The original description implies that there were other syntypes. The lectotype and 323 other specimens were used in preparing the above treatment.

## 26. Ips knausi Swaine Fig. 167

Ips knausi Swaine, 1915, Canadian Ent. 47:355 (Holotype, male; Cloudcroft, New Mexico; Canadian Nat. Coll., 9305)
Diagnosis.- This species is distinguished from emarginatus LeConte by the presence of interstrial punctures, by the presence of spine 4 on the elytral declivity, and by the distribution.

Male.- Length 4.9-6.4 mm, 2.7 times as long as wide; color dark brown to almost black.

Frons and pronotum as in emarginatus.
Elytra as in cmarginatus except interstriae finely, uniseriately punctured to base, lower point on declivital spine 3 usually slightly longer than upper point; spine 4 almost always present.

Female.- Similar to male except major epistomal tubercle smaller; spine 3 on declivity smaller, sometimes appearing as two separate denticles.

Distribution.-S Nevada and E South Dakota to Arizona and New Mexico.

USA: Arizona: Chiricahua Mts., Crook N.F., Flagstaff, Huachuca Mts., Jacobs Lake. Kaibab N.F.. Santa Catalina Mts., Tucson. Colorado: Allens Park, Bailey, Colorado N.F., Estes N.P., Electra Lake near Durango, Evergreen, Jones Ranch near Durango, Las Animas, Lyons, Pine River in La Plata Co., Uncompahgre N.F., Vallecito in La Plata Co., Williams. Nevada: Austin. New Mexico: Cloudcroft, Lincoln N.F., Ruidosa. South Dakota: Black Hills, Elmore. Utah: Panguitch.

Host.- Pinus ponderosa.
Biology.- Evidently similar to emarginatus.

Notes.- The above treatment was based on 141 specimens, several of which were compared to the holotype.

## 27. Ips calligraphus (Germar) Fig. 169

Bostrichus calligraphus Germar, 1824, Insectorum species novae autimus cognitae, descriptionibus
illustratae p. 461 Syntypes: Kentack!; presumatly in the Berlin Xuseum).
Bostrichus exesus Say, 1826, J. Acad. Nat. Sci. Philadelphia 5:255 (Syntypes: presumably Pennsylvania; evidently lost); LeConte, 1876, Proc. Amer. Philos. Soc. 15:363. Synonymy
Tomicus praemorsus Eichhoff, 1868, Berliner Ent. Zeitschr. 11:401 (Syntypes?; Amerique boreali; presumably lost with Hamburg Mus.); Eichhoff, 1876, Stettiner Ent. Zeit. 37:378. Synonymy
Tomicus interstitialis Eichhoff. 1869, Berliner Ent. Zeitschr. 12:273 (Holotype, male; Jamaica; Brussels Mus.); Hopping, 1965, Canadian Ent. 97:803. Synonymy
Ip.s ponderosae Swaine, 1925, Canadian Ent. 57:197 (Holotype, male; Coconino N.F., Arizona: Canadian Nat. Coll., 1377); Hopping, 1965, Canadian Ent. 97:803. Synonymy
Diagnosis. - The six pairs of spines on the elytral declivity distinguish this species from all other American $I p s$.

Male.- Length 3.8-5.9 mm, 2.7 times as long as wide; color dark reddish brown.

Frons broadly convex, weakly impressed above epistoma; surface shining, rather coarsely, closely granulate below upper level of eves, more sparsely granulate above and intermixed with obscure punctures, a major median tubercle equal distance between epistomal margin and upper level of eyes, another smaller major median tubercle on epistoma; epistoma with a transverse row of tubercles. Vestiture of fine, long, sparse hair.

Pronotum 1.2 times as long as wide; sides feebly arcuate on basal two-thirds, rather narrowly rounded in front; summit indefinite, well in front of middle; anterior slope rather coarsely asperate; posterior areas smooth, shining, punctures very fine on dise, slightly larger toward lateral margins. Disc glabrous; fine, long hair moderately abundant on remaining areas.

Elytra 1.6 times as long as wide; sides almost straight and parallel on basal two-thirds, declivital spines 3,5 , and 6 interrupting outline, transverse subapical margin one-third as wide as declivity; striae 1 moderately, others feebly impressed, punctures moderately small, deep; interstriae almost twice as wide as striae, smooth, shining, punctures fine, sparse on anterior half. Declivity broadly, deeply excavated as in allied species; spine 1 small, pointed, slightly mesad of striae 2, spine 2 in line with striae 2 , moderately large, somewhat pointed but with elevated enlarged base extending from near its apex to

Fig. 169. Ips calligraphus: 1, 3, 5, male; 2, 4, female. (After Hopping 1965:804.)
base of spine 3 ; spine 3 large, capitate, tip bent ventrad; spine 4 rather small, pointed, spine 5 conical, in position occupied by lateral extremity of elevated subapical margin; spine six usually basally subcontiguous with subapical margin; subapical margin short, about one-third as wide as distances between third spines; face of concavity essentially as in perturbatus. Vestiture of fine, long hair, more abundant on sides and declivity.

Female.- Similar to male except declivital spines, particularly 3 , slightly smaller.

Distribution.- California and Quebec to Jamaica and Honduras.

CANADA: Ontario, Quebec. USA: Alabama, Arizona, Arkansas, California, Colorado, Delaware, District of Columbia, Florida, Georgia, Indiana, Louisiana, Maryland, Massachusetts, Mićhigan, Minnesota, Mississippi, Missouri, Montana, Nebraska, New Hampshire, New Jersev, New Mexico, New York, North Carolina, Ohio, Pennsylvania, South Carolina, South Dakota, Tennessee, Texas, Utah, Virginia, West Virginia, Wisconsin, Wyoming. MEXICO: Chiapas, Hidalgo, Jalisco, Mexico, Michoacán, Sinaloa. CENTRAL AMERICA: Guatemala, British Honduras, Honduras, Nicaragua. OTHER COUNTRIES: Babama Islands, Dominican Republic. Jamaica.

Hosts.- Pinus caribaea, P. echinata, P. elliottii, P. michoacana, P. montezumae, P. occidentalis, P. oocarpa, P. ponderosa, P. pseudostrobus, P. resinosa, P. rigida, P. strobus, $P$. taeda.

Biology.- The habits apparently are about as in integer.

Notes.- The above treatment was based on the type series of ponderosae, on the holotype of interstitialis, and on more than 1,000 other specimens. The name calligraphus was based on the series of Hopkins, Blackman, Eggers, and Swaine.

Lanier (1972) divided this species into interstitialis (Mexico, Central America, and one Arizona series) and calligraphus (USA) with different subspecies of the latter in the eastern and western areas. Using the characters employed by Lanier, I am neither able to confirm his results, nor am I able to find other characters that subdivide this species. His hybridization results must be evaluated and interpreted as any other taxonomic character. Until considerably more information is available only one species should be recognized.

## 28. Ips grandicollis (Eichhoff)

Fig. 170-171
Tomicus grandicollis Eichhoff, I868 (January), Berliner Ent. Zeitschr. 11:402 (Syntypes?; Amerique boreali; presumably lost with Hamburg Mus.)
Tomicus cacographus LeConte, 1868 (September), Trans. Amer. Ent. Soc. 2:162 (Lectotype, sex?; Illinois, lectotype bears orange disk; Mus. Comp. Zool., present designation); Blandford, 1898, Ent. News 9:6. Synonymy
Tomicus cribricollis Eichhoff, 1869, Berliner Ent. Zeitschr. I2:273 (Holotype, male; Mexico; Brussels Mus.); Wood, 1977. Great Basin Nat. 37:385. Synonymy
Ips chagnoni Swaine, 1916, Canadian Ent. 48:186 (Holotype, male; Montreal Island, Quebec; Canadian Nat. Coll. 9310); Hopping, 1965, Canadian Ent. 97:423. Synonymy
Ips cloudcrofti Swaine, 1924, Canadian Ent. 56:70 (Holotype, female; Cloudcroft, New Mexico; Canadian Nat. Coll., 699): Wood, 1957, Canadian Ent 89:397. Synonymy
Diagnosis.- This species is distinguished from lecontei Swaine by the presence of only one major frontal tubercle, which is placed on the median line well above the epistomal margin. It is somewhat variable geographically.

Male.- Length 2.9-4.6 mm, 2.7 times as long as wide; color dark reddish brown.

Frons as in calligraphus (Germar) except lower, median, epistomal tubercle absent, all granules averaging slightly larger, not quite as abundant. Pronotum 1.26 times as long as wide; as in calligraphus except punctures on dise varying from moderately fine to rather coarse on dise, rather coarse in lateral areas.

Elytra 1.5 times as long as wide; outline about as in calligraphus except subapical margin wider, with fewer dentations; striae 1 moderately, others feebly impressed, punctures rather coarse, deep, close; interstriae about one and one-half times as wide as striae, smooth, shining, punctures fine to rather coarse, usually extending from declivity to base on 5-9, variable on 2-4 but almost always present at least on posterior fourth (see taxonomic notes below). Declivity essentially as in calligraphus except spine 1 on interstriae 2 ; spine 3 stout, blunt, with a distinct ventral hook at apex; spines 2, 4, and 5 in normal positions; subapical margin wider than calligraphus, ending laterally near base of spine 5 . Anterior tibia usually with three teeth.

Female.- Similar to male except major frontal tubercle evidently slightly smaller;
declivital spine 3 slightly smaller, devoid of ventral hook. Anterior tibia usually with four teeth.

Distribution.-S Manitoba and S Quebec to Honduras and Florida; introduced into Australia.

Fig. 170. Ips spp., dorsal and lateral aspects of male declivity: 1, 4, grandicollis; 2, montanns; 3, 5, paraconfusus; 6. lecontei. (After Hopping 1965:425.)

CANADA: Manitoba, Ontario, Quebec. USA: Alabama, Arkansas, Connecticut, District of Colmmbia, Florida, Georgia, Illinois, Indiana, Louisiana, Maine, Maryland, Massachusetts, Michigan, Minnesota, Mississippi, Missouri, Nebraska, New Hampshire, New Jersey, New Mexico, New York, North Carolina, Ohio, Pennsylvania, South Carolina, Tennessee, Texas, Virginia, West Virginia, Wisconsin. MEXICO: Chiapas, Chihuahua, Durango, Hidalgo, Jalisco, Mexico, Michoacán, Morelos, Puebla, Sinaloa. CENTRAL AMERICA: Guatemala, Honduras, Nicaragua. OTHER COUNTRIES: Bahama Islands, Dominican Republic, Australia (introduced).
Hosts.-Pinus banksiana, P. caribaea, P. durangensis, $P$. cchinata, $P$. montezumac, $P$. oocarpa, P. palustris, P. ponderosa, P. pseudostrobus, P. resinosa, P. rigida, P. strobiformis, P. sylvestris, P. taeda, P. tenuifolia, P. cirginiana.

Biology.- The habits evidently are very similar to calligraphus except that it is able to breed successfully in smaller limbs, as well as in larger material.
Notes. - The above treatment was based on the type series of cacographus, chagnoni, and cloudcrofti, on the holotype of cribricollis, and on 1,334 other specimens. The first of two syntypes in the LeConte collection, labeled Type No. 1017, is here designated as the lectotype of cacographus LeConte.
There is distinct geographical variation in the number and position of punctures on discal interstriae 2-4. Specimens from eastern Canada and the northeastern United States rarely have any punctures on the anterior three-fourths; specimens in my series from Georgia are punctured to the middle of the disc; those from New Mexico to Honduras are sparsely punctured to the base at least on interstriae 3 .
Males from a series from DeQueen, Arkansas, and others from Carapan, Michoacán, were dissected for study of the genitalic structures. In both series the apex of the aedeagus resembled Lanier's (1970:1154) Figure 37, of grandicollis, but the basal struts were short, as in his Figure 35, of cribricollis. Five males from each series gave aedeagus/struts ratios of 1.11-1.17 for the Arkansas specimens, and 1.10-1.17 for the Michoacán series. Evidently Lanier's grandicollis specimens were larger than normal; increased body size is often associated with proportionately longer struts. It should be noted that specimens from Canada and the

Great Lakes area average slightly larger in size than those from the southern two-thirds of the range.
29. Ips lecontei Swaine

Figs. 170-171
Ips lecontei Swaine, 1924, Canadian Ent. 56:70 (Holotype, male; Arizona; Mus. Comp. Zool., 1025, second specimen in LeConte series of confusus)
Diagnosis.- This species is distinguished from other American 5 -spined Ips by the absence of a major median frontal tubercle in the male; it is replaced by a pair of submedian tubercles on the male epistoma.

Male.- Length $4.0-4.7 \mathrm{~mm}, 2.6$ times as long as wide; color very dark brown.

Frons broadly convex, weakly impressed above epistoma; surface shining, rather coarsely, moderately closely granulate to above upper level of eyes, granules above eyes gradually replaced by fine, deep punctures; central area often with a pair of transverse tubercles; epistoma bearing a row of tubercles, median pair conspicuously enlarged. Vestiture of fine, sparse, long hair.
Pronotum 1.2 times as long as wide; essentially as in calligraphus (Germar) except summit more distinct; posterior area smooth, shining, punctures small to moderately large, close, not larger in lateral areas.

Elytra 1.5 times as long as wide; outline as in grandicollis (Eichhoff); striae 1 moderately, others obscurely impressed, punctures moderately large, deep; interstriae almost twice as wide as striae, punctures fine, distinct, regular on posterior half, very sparse on anterior half of disc. Declivity as in grandicollis; spine 1 on lateral half of interstriae 2, spine 2 on interstriae 4 ; spine 3 large, with a dorsal hump on is basal half, a ventral notch and hook on its distal half; spines 4 and 5, declivital face, and subapical margin essentially as in grandicollis except lateral end of subapical margin with a feeble notch suggesting a sixth spine. Vestiture essentially as in allied species. Anterior tibia with three teeth.
Female.- Similar to male except major frontal tubercles, particularly on epistoma, reduced in size; declivital spine 3 slightly smaller with dorsal hump and ventral notch usually less conspicuous; anterior tibia with four teeth.

Distribution.- N Arizona and S New Mexico to Honduras.

USA: Arizona: Chiricahua Mts., Coconino N.F., Jerome, Prescott, Santa Rita Mts., Tonto N.F. New Mexico: Lake Roberts. MEXICO: Chihuahua: Mesa del Huracan, Olingas. Durango: El Salto. Colima: Colima. Jalisco: Mazamitla, Mt. Colima. HONDURAS: Buenos Aires in Cortez.
Hosts.-Pinus ponderosa and $P$. pseudostrobus.

Biology.- Apparently about as in calligraphus.

Notes. - The above treatment was based on the holotype and on 433 other specimens.

## 30. Ips montanus (Eichhoff)

Figs. 170-171
Tomicus montanus Eichhoff, 1880, Die Europäischen Borkenkäfer, p. 219 (Lectotype, female; California; U.S. Nat. Mus., present designation)
Ips vancouveri Swaine, 1916, Canadian Ent. 48:188 (Holotype, male; Quathiaski Cove, Vancouver Island, British Columbia; Canadian Nat. Coll., 9304); Wood, 1957, Canadian Ent. 89:398. Synonymy
Diagnosis.- This species is distinguished from paraconfusus Lanier by the larger size, by the poorly developed or absent frontal fovea in both sexes, by the position of the major male median tubercle being much higher on the male frons, and by the host.
Male.- Length $4.6-5.4 \mathrm{~mm}, 2.6$ times as long as wide; color very dark brown.

Frons convex, a slight impression above epistoma; surface shining, rather coarsely granulate to well above eyes, gradually replaced above by small punctures; a coarse median tubercle with its upper margin at upper level of eyes; epistoma with a row of coarse tubercles except at median line; vestiture of fine, sparse, long hair.

Pronotum 1.13 times as long as wide; as in lecontei except punctures in posterior areas moderately coarse.
Elytra 1.5 times as long as wide; outline and disc about as in lecontei. Declivity much as in lecontei except spine 1 on median half of interstriae 3 (closer to spine 2 than to suture), other spines evidently slightly more slender, and subapical margin without a feeble notch near its lateral end. Anterior tibia with three teeth.

Female.- Similar to male except frons with a shallow median fovea at upper level of eyes, a feeble major tubercle often
between fovea and epistomal margin; granules on epistomal margin much smaller; declivital spine 3 slightly smaller, with dorsal hump and ventral notch less distinct; anterior tibia with four teeth.

Distribution.-S British Columbia and W Montana to central California.
CANADA: British Columbia: Campbell River, Courtenay, Kaslo, Qualicum, Trinity Valley. USA: California: Avalanche Meadow in Tulare Co., Badger Flat in Lassen Co., Callihan, Caribou Lake in Siskiyou Co., Cisco, Deadfall Lakes in Siskiyou Co., Fallen Leaf Lake, Grassy Lake in Lassen Co., Kingvale, Klamath, Mt. Brewer, Old Soda Springs, Trinity Center, Weed, Yosemite. Idaho: Avery, Coeur d'Alene, Collins, Deception Creek Experimental Forest, Evansville, Kootenai, Nickle Plate Mt. in Kaniksu N.F., Pierce, Priest Lake, Priest River, Prichard, St. Joseph. Montana: Kootenai N.F. Oregon: Crater Lake, Lake of the Woods, Prospect, Willamette Pass. Washington: Metaline Falls, Mt. Rainier, Naches, Spokane Falls.

Host.- Pinus monticola, uncommon in $P$. albicaulis, P. balfouriana.
Biology. Apparently very similar to paraconfusus.

Notes. - The above treatment was based on 288 specimens and on one female cotype from the original series.
Eggers (1933:20) examined the syntypic original series before the Hamburg Museum was destroyed and indicated that the specimens were labeled either "Cisco" (California) or "Cal." Schedl (pers. comm.) indicated that all specimens he saw in this series in the Hamburg Museum were labeled as cotypes. There is one female in the Swaine material at the Canadian National Collection (Wood 1957:398) bearing a small triangular blue-colored label, a rectangular label with the word "Cal.," apparently in Eichhoff's hand, a rectangular label with " 14 " in Eichhoff's hand, another "au confusus Lec.?" apparently written by E. A. Schwarz, and one "Tomicus montanus Eich., Type," written by E. A. Schwarz. This was species no. 14 in a series of more than 100 species sent to Schwarz by Eichhoff prior to 1896; it was borrowed by Swaine (pers. comm.) prior to 1920 for an intended revision of the genus. Because Eichhoff did not designate a type, this specimen, and others in his series, could have been no more than syntypes regardless of the "Type" label. Because the labels on this specimen are similar to those seen on other original Eichhoff type material of other species in the U.S.

National Museum and in the Eggers and Schedl collections, because part of the original series was from California, and because Swaine (pers. comm.) had borrowed several types for an intended revision of the genus about 1920, without returning them (as curator of the Swaine collection, I returned in 1955 to the USNM all except the Eichhoff type. I did not realize until 1974 that the Eichhoff type had also been borrowed from the USNM), I regard this specimen as a syntype and here designate it as the lectotype of montanus Eichhoff. A second specimen in the Canadian National Collection, labeled "Cisco, Julio '69," and "Ips montanus Eichhoff, mit type vergleichen, Eggers det.," is probably from the original series also, but there are no labels suggesting status as a cotype. The lectotype is to be returned to the U.S. National Museum.

## 31. Ips paraconfusus Lanier <br> Figs. 170-171

Ips paraconfusus Lanier, 1970, Canadian Ent. 102:1145 (Holotype, female: Avery, Calaveras Co., California; Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from montanus (Eichhoff), as noted in the above diagnosis for that species. It is distinguished from confusus (LeConte) with great difficulty by the small, often obscure punctures on the frons, by the larger, more broadly rounded median major tubercle immediately above the epistoma, and by other minor characters.

Male.- Length 3.8-4.3 mm, 2.6 times as long as wide; color very dark brown.

Frons as in montanus except with a rather deep, median fovea at upper level of eyes, major median tubercle near, almost on epistomal margin. Pronotum and elytra as in montanus. Anterior tibia with three teeth.
Female.-Similar to male except major median frontal tubercle absent, epistomal granules much smaller; frons and anterior area of pronotum with more abundant pubescence; declivital spine 3 slightly smaller, with its dorsal hump and ventral hook less distinct; anterior tibia with four teeth.
Distribution.-SW Oregon, W Nevada, and California.

USA: California counties: Alameda, Butte, Calaveras, Contra Costa, Del Norte, El Dorado, Fresno, Glenn,

Kern, Lake, Lassen, Los Angeles, Madera, Marin, Mariposa, Napa, Nevada, Placer, Plumas, Riverside, San Bernardino, San Diego, San Mateo, Santa Barbara, Santa Clara, Santa Cruz, Shasta, Sierra, Siskiyou, Trinity, Tulare, Tuolumne. Nevada: Minden. Oregon: Ashland, Black Rock in Polk Co., Central Point, Corvallis, Grants Pass. Soda Creek.

Hosts.- Pinus attenuata, P. coulteri, P. jeffreyi, P. lambertiana, and P. ponderosa; rarely in P. contorta.

Biology.- Unthrifty, fallen, or cut trees are usually selected for attack, although healthy trees have been killed under certain conditions. The longitudinal parental gallery systems usually include three to five elongate egg galleries in a rather broad tuning fork pattern. Larval mines are comparatively long. Chamberlin (1958) reports three to five generations per year. More detailed studies are reported by Cameron and Borden (1967), Chansler (1964), Gara (1963), Silverstein, Rodin, and D. L. Wood (1966), Strubble and Hall (1955), D. L. Wood (1963), D. L. Wood and Bushing (1963), and D. L. Wood and Vité (1961).

Notes.- The above treatment was based on the female holotype and on about 1,200 other specimens. Literature prior to 1970 treated this species under the name confusus.

## 32. Ips confusus (LeConte)

Tomicus confusus LeConte, 1876, Proc. Amer. Philos. Soc. 15:364 (Lectotype, female; Southern California; Mus. Comp. Zool., 1025, present designation)
Diagnosis.- This species is distinguished from paraconfusus Lanier by characters summarized in the above key and in the diagnosis of that species. It is not distinguishable by external characters from hoppingi Lanier.

Male.- Length 3.5-4.2 mm, 2.6 times as long as wide; color very dark brown.

As in paraconfusus except frons usually devoid of punctures to well above eyes; major median frontal tubercle usually slightly smaller, more acutely pointed, declivital punctures slightly larger, more abundant, closer.

Female.- Differing from male as in paraconfusus.

Distribution.-S California and Colorado to Arizona and W Texas.

U'SA: Arizona: Chiricahua Mts., Flagstaff, Grand Canyon, Prescott, Seligmans, Sweetwater, Tueson, Walnut

Canvon. Williams, Window Rock. California: Backus, Chuchupate Ranger Station in Ventura Co., Coleville, Frazier Park in Kern Co., Gorman, Joshua Tree N.M., Mono Co., Mt. Pinos, Pinvon Flat in Palm Desert, Summerville, Valvermo, Ventura Co., Wrightwood. Colorado: Canyon City, Cortez, Colorado N.M., Crestone.

Ft. Garland, Grand Junction, Mancos, Manitou, Mesa Verde N.P., Norwood, San 1sabel N.F., Turkey Creek in El Paso Co., Uncompahgre N.F. Nevada: Austin, Summit, Baker. Charleston, Pequop Pass. New Mexico: Capitan, Cloudcroft, Corona, Datil Mts., Grants, Kingston, Lake Roberts, Lincoln N.F.. Los Alamos,

Fig. 171. Ips spp., male heads: 8, 11, grandicollis: 9, paracoufusus; 10, montanus; 12, lecontei. (After G. Hopping 1965:427.)

Magdalena, Ruidosa. Santa Fe. L'tah: Beaver, Dave's Hollow in Dixie N.F., Gooseberry in Fish Lake N.F., La Sal Mts., Lofgreen, Mercur, Mt. Carmel, Panguitch. Parowan Canyon. Texas: Davis Mts. Wyoming: Atlantic City (one dead specimen in an incomplete tunnel in Pinus flexilis 50 miles from the nearest known Pinus celulis). MEXICO: Baja California: Tecate. Chihuahua: Mesa del Huracan.

Hosts.- Pinus edulis, P. monophylla, and rarely in other hosts.

Biology.- Apparently as in paraconfusus except that egg galleries evidently average much shorter.

Notes. - This species was based on three specimens, only one of which remains in the LeConte collection. That female, bearing the labels "Cala." and "Type No. 1025 " and "dissected by Lanier," is here designated as the lectotype of confusus. The above treatment was based on the lectotype and on 233 other specimens.

The female pars stridens and the male genitalia are mentioned below under the presumed sibling species hoppingi Lanier.

## 33. Ips hoppingi Lanier

Ips hoppingi Lanier, 1970. Canadian Ent. 102:1145 (Holotype, female; 20 miles or 32 km S Chiri(ahua Nat. Mon., Arizona: Canadian Nat. Coll.)
Diagnosis.- Lanier (1970) established this as a sibling species of confusus on the basis of its wider female pars stridens with narrower striations, and its comparatively longer struts on the male genitalia.

Male- Exactly as in confusus with the possible exception of the characters cited by Lanier.

Female.- Differing from the male as in confusus.

Distribution.-S Arizona and E Texas to Mexico and Hidalgo.
USA: Arizona: Ash Canvon, Huachuca Mts., Chiricahua N.M. Texas: Big Bend N.P. MEXICO: Chihuahua: Mesa del Huracân. Hidalgo: Zimapan. Mexico: Temaxcaltepec.

Host.- Pinus cembroides.
Biology. - As in confusus.
Notes.- This species was established on the basis of three characters, none of whose validity is fully established. In the male genitalia, Lanier's measurements of strut length/aedeagus length overlap even though series data were not presented separately; in Scolytidae generally strut length may be related as much to overall beetle size as it is to taxonomic difference. The differences in striations of the female pars stridens possibly may present a valid character, but Lanier presented a composite series in his data that confuses geographical variation with possible taxonomic differences. Although the karyotypes of these series may present valid specific differences, their validity as a taxonomic character is not yet fully established and must be verified by other workers. The attempted hybridization of hoppingi and confusus, based on five mated females, is suggestive of the validity of hoppingi but should be confirmed. Either hoppingi is a valid sibling species or else a synonym of confusus.

# Tribe DRYOCOETINI 

Dryocoetoideae Lindemann, 1876, Bull. Soc. lmp. Nat. Moscou 51:165 (Type-genus: Dryocoetes Eichhoff, 1864) Thamnurginae Nüsslin, 1911, Zeitschr. wissensch. Insektenbiol. 7:377 (Type-genus: Thaminurgus Eichhoff, 1864) Taphrorychini Reitter, 1913, Wiener Ent. Zeit. 32(Beiheft):29 (Type-genus: Taphrorychus Eichhoff, 1878)

Anatomical features. - The frons is usually sexually dimorphic, with the male sometimes impressed (Dendrocranulus), the female is sometimes ornamented by setae (some Dryocoetes), the eye is sinuate to emarginate (or completely divided in one African genus), the antennal funicle is $4-5$-segmented, the club is either obliquely truncate (Dryocoetes, Coccotrypes) or the sutures on the posterior face are very strongly displaced toward the apex, the pronotum is weakly to moderately declivous on the anterior face and asperate (smooth in one African genus), its lateral margins are rounded, the anterior coxae are contiguous, and the declivital sculpture is simple.

Biological features.- All are polygamous; American Dryocoetes are phloeophagous, the species of Lymantor are semixylophagous, the Dendrocranulus are stem borers in cucurbit vines, and the Coccotrypes may be either phloeophagous or spermophagous. All American Coccotrypes apparently have been introduced to America in historic times; Lymantor and Dryocoetes were derived from the Asian fauna rather recently, and Dendrocranulus from tropical America. Dendrocranulus is almost indistinguishable from some African Xylocleptes. Coccotrypes reproduces by consanguineous polygyny that apparently includes facultative arrhenotokous parthenogenesis. Eggs are usually placed in niches. Larval mines may be individual or communal.

Taxonomy.- Generic limits in this tribe have not been carefully studied. Because the overwhelming majority of species occur only in the Old World, no attempt was made to resolve the problem at this time.

Genus Lymantor Lovendal

Lymantor Lovendal, 1889, Ent. Medd. 2:25 (Type-species: Lymantor sepicola Lovendal $=$ Tomicus coryli Perris, monobasic)
Diagnosis.- This genus is distinguished by the 4 -segmented antennal funicle, by the very strongly procurved, aseptate sutures of the antennal club, and by other characters included in the above generic key.

Description.-Length $1.5-1.9 \mathrm{~mm}, 2.8$ times as long as wide; color reddish brown. Frons sexually dimorphic, sculpture simple. Eye oval, shallowly emarginate; finely granulate. Antennal scape elongate; funicle 4 -segmented; club subcircular, moderately large, sutures strongly procurved, indicated only by setae, 1 reaching middle of club. Pronotum longer than wide, anterior third moderately declivous and finely asperate; margins rounded. Scutellum small. Elytral disc with strial and interstrial punctures confused; declivity steep, broadly convex. Vestiture hairlike. Tibiae rather broad, armed by several teeth on outer margin.

Distribution.- N North America and Europe; four species, one occurs in eastern Canada and the United States and one in Alaska.

Notes.- Schedl (1964:306) placed Lymantor in synonymy under the older genus Triotemnus Wollaston. Although I am acquainted with only half the species of Triotemnus, but with all the species of Lymantor, I see no real intergradation between the two groups in those characters that to me are quite significant. For this reason Lymantor is retained as a valid genus.

## Key to the Species of Lymantor

1. Pronotum more slender, 1.25 times as long as wide, dise smooth and shining in both sexes; declivity more uniformly convex, punctures on striae and interstriae in rows, smaller, vestiture uniformly shorter; Alaska; $1.7-1.9 \mathrm{~mm}$
2. alaskanus Wood

- Pronotum less slender, 1.1 times as long as wide, male disc partly reticulate; declivital interstriae 2 distinctly impressed, punctures confused, more strongly granulate, vestiture longer, less regularly present: Michigan and Quebec to Kansas and Mississippi; Acer, etc.; $1.5-1.8 \mathrm{~mm}$

2. decipiens (LeConte)

## 1. Lymantor alaskanus Wood

Lymantor alaskanus Wood, 1978. Great Basin Nat. 38:399 (Holotype, male: Bonanza Creek, 30 miles southeast Fairbanks, Alaska; Wood Coll.)
Diagnosis.- This species is distinguished from decipiens (LeConte) by the larger size and more slender body, by the different male frons, by the smaller, less deeply impressed pronotal and elytral punctures, and by the different elytral declivity.

Male.- Length $1.7-1.9 \mathrm{~mm}, 2.9$ times as long as wide; color reddish brown.

Frons strongly convex from slightly below upper level of eyes to vertex, lower twothirds of area below upper level of eyes transversely impressed (less strongly but much more extensively than in decipiens); surface shining, punctures rather fine, moderately close except very sparse on median fourth; vestiture fine, short, inconspicuous.

Pronotum 1.25 times as long as wide; outline about as in decipiens except sides more strongly converging posteriorly on posterior half; surface smooth, shining, punctures slightly finer, not as deep as in decipiens.

Elytra 1.8 times as long as wide, 1.8 times as long as pronotum; as in decipiens except discal punctures slightly smaller, much less strongly impressed, declivity more evenly convex, striae 1 and 2 not impressed, with punctures in rows, smaller than on disc, interstriae 1 much less strongly elevated, 2 not impressed, 2 and 3 each with a sparse row of very fine punctures, their upper margins much more feebly granulate, vestiture finer, shorter, more regularly present from base to apex.

Female.- Similar to male except transverse frontal impression not as deep, upper area less strongly convex.

Distribution.-Alaska.

ALASKA: Bonanza Creek, 30 miles SE Fairbanks, 18 -VII-78. No. 51, sticky trap baited with lpenol and alphapinene, R. A. Werner.
Notes.- The above treatment was based on the type series of 19 specimens.

## 2. Lymantor decipiens (LeConte)

Xylocleptes decipiens LeConte, 1878. Proc. Amer. Philos. Soc. 17:62.4 (Holotype, female; Detroit: Mus. Comp. Zool., 1294)
Diagnosis.- This species may be recognized from characters included in the above key.

Female.- Length 1.5-1.8 mm, 2.8 times as long as wide; color reddish brown.

Frons rather strongly, transversely impressed from epistoma almost to upper level of eyes, convex above; a slight median elevation at upper level of eves; surface finely punctured, most punctures finely subgranulate; vestiture hairlike, inconspicuous except small epistomal brush.

Pronotum 1.1 times as long as wide; widest at middle, sides moderately arcuate, converging equally anteriorly and posteriorly, rather broadly, equally rounded on anterior and posterior margins; anterior third moderately declivous and armed by numerous, small asperities; posterior areas smooth, with moderately abundant minute points and rather sparse, coarse, deep punctures. Glabrous except near margins.

Elytra 1.7 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; discal punctures confused, rather coarse, deep, separated by one or two diameters of a puncture. Declivity rather steep, broadly convex, somewhat flattened; punctures of striae 1 and 2 in rows, smaller than on disc; interstriae 1 weakly elevated, 2
broadly, weakly impressed, punctures on 1-3 feebly granulate. Vestiture hairlike, sparse and short on dise, moderately long and apparently more abundant on declivity.

Male.-Similar to female except frontal impression much smaller, not as deep, frontal punctures rather coarse.

Distribution.-Michigan and Quebec to Kansas and Mississippi.

CANADA: Ontario: Toronto. Quebec: Laniel, La Trappe, St. Etienne. USA: Iowa: Ames. Kansas: Lawrence. Kentucky: Morehead. Maine: Monmouth. Massachusetts: Framingham, Petersham. Michigan: Detroit. Minnesota: Duhthth. Mississippi: Iuka, Trimcane Swamp. New Jersey: Lahaway. New York: Axton, Ithara, Syracuse. Pennsylvania: Clark's Valley, Dauphin, Pocono Lake. Virginia: Rosslyn. West Virginia: "Hopk. W. Va. 7113 " and "7123."

Hosts.- Acer rubrum, A. saccharinum, A. sp., Hamamelis virginiana, Rhus typhina, Salix sp.

Biology.- These polygynous beetles attack only small, completely dead, dry branches of living maple trees and seedlings, rarely in other hosts. The entrance tumnel extends through the bark to a point within the wood where two to four egg galleries radiate, usually following the grain of the wood. There is little or no nuptial chamber. The egg galleries may have short branches leading either deeper into the wood or to the surface of the sapwood. The eggs are deposited in niches and the short larval tunnels are transverse. Whether or not the adults and larvae utilize the dark fungal growth in their nutrition has not been determined.

Notes. - The above treatment was based on the holotype and on 33 other specimens.

## Genus DENDROCRANULUS Schedl

Dendrocranulus Schedl, 1937, Arch. Inst. Biot. Veg. Río de Janeiro 3:165 (Type-species: Dendrocramulus tardus Schedl, subsequent designation by Schedl, 1938, Archiv. Naturgesch., n.s., 7(2):169)
Diagnosis.- This genus is distinguished with some difficulty from the Old World Xylocleptes Ferrari by the less strongly procurved, much less distinct sutures of the
antennal club, by a different type of frontal sculpture, and by the much more conservative sculpture of the elytral declivity.

Description.- Length $1.2-2.7 \mathrm{~mm}$, 2.5-3.0 times as long as wide; color light yellowish brown to very dark reddish brown. Frons usually dimorphic, male feebly impressed to strongly excavated, female flattened to convex; female often with abundant vestiture. Eye oval, emarginate; finely granulate. Antennal scape elongate; funicle 5 -segmented; club rather small, subcircularly flattened, with two obscure, moderately procurved sutures indicated by setae. Pronotum longer than wide; finely to coarsely asperate on anterior half, punctured to asperate behind; summit poorly defined; basal and lateral margins rounded. Scutellum small. Elytra elongate, striate; declivity convex to broadly excavated, devoid of denticles. Tibiae rather broad, armed by a series of marginal teeth.

Distribution.- Central United States to Argentina; about 30 species are known; 23 occur from Utah, Kansas, and Florida to Panama.

Biology.- These species infest unthrifty, overmature, or recently cut stems of various representatives of the Cucurbitaceae. The attack evidently is initiated by the male at a leaf node, where an entrance tunnel and small nuptial chamber are formed. Evidently at least some species are polygynous; others may be monogamous. The fibrous nature of the host, the longitudinal, elongate egg galleries, and the very short life cycle have made this and other items in behavior difficult to determine.

Notes. - The status of this genus might be questioned. None of the American species exhibit the structure of the male declivity found in related European and African genera, nor do any of them have sutures of the antennal club as well defined as in Xylocleptes. In spite of the closeness of the two groups, I prefer to maintain them as separate genera.

## Key to the Species of Dendrocranulus

1. Posterolateral margin of elytra acutely elevated from apex to interstriae 7, declivital face convex to moderately flat

2(1). Discal punctures on pronotum largely replaced by granules; Nayarit to Honduras; 1.2-1.5 mm ..................................................................... 1. consimilis Wood

- Discal punctures on pronotum clearly impressed 3

3(2). Elytral declivity rather strongly convex, striae 2 and 3 straight to their apices; Costa Rica; 1.7-2.0 mm
2. limus Wood

- Elytral declivity somewhat flattened, striae 2 and 3 curve toward suture near apex 4

4(3). Pronotal and elytral punctures smaller, not as deep; elevated posterolateral margin of declivity short, sharply defined only near apex; Costa Rica; 1.4-1.5 mm
3. tardulus Wood

- Pronotal and elytral punctures coarse deep; posterolateral margin of declivity longer and acutely elevated; Honduras to Costa Rica; 1.9-2.0 mm

4. tardus Schedl

5(1). Declivity usually steeper, more narrowly convex, lateral margins more gradually rounded in both sexes, if impressed, interstriae 1 elevated and impression not extending lateral from interstriae 3 in either sex; female frons usually much more strongly pubescent, male frons devoid of excavation or prominent tubercle on vertex 6

- Declivity often more gradual, more broadly convex to shallowly concave, at least in male, impression often extending from suture to striae 4, if convex, male frons strongly impressed and armed by a median elevation on vertex; female frons sparsely pubescent; male mandible usually with inner cusp directed cephalad 14
6(5). Pronotal disc clearly, rather deeply punctured over at least median half ..... 7
- Pronotal dise with transverse or flat, rounded granules, occasionally with a few punctures near median line ..... 12
7(6). Smaller, more slender, at least 2.7 times as long as wide .....  8
Larger, stouter, less than 2.5 times as long as wide17

8(7). Pronotal surface rather strongly reticulate, discal punctures not accompanied by an elevation; male frons feebly impressed; Costa Rica; 1.3-1.4 mm
5. pumilus Wood

- Pronotal surface shining, obscurely subreticulate, most discal punctures accompanied by an elongate, transverse, low elevation; male frons strongly, transversely impressed from epistoma to upper level of eyes
$9(8)$. Declivital interstriae punctured, devoid of granules; strial punctures small, rather deep; male frons more strongly impressed, with a large, shining, impunctate area on lower half; Honduras; $1.2-1.3 \mathrm{~mm}$
- Declivital interstriae 1-3 each with a row of fine granules; strial punctures very small, shallow; male frons somewhat less strongly impressed, impunctate area much smaller, lateral areas with fine granules; Costa Rica; 1.5-1.7 mm

7. vicinalis Wood

10(7). Pronotal disc obscurely reticulate; declivital setae on interstriae 1 and 2 stout, distinctly shorter than distance between rows; male frons reticulate, punctured; female frons moderately convex, reticulate, rather coarsely punctured, with rather sparse, long, fine hair; Costa Rica; 1.7-2.1 mm
8. securus Wood

Pronotal dise shining, not at all reticulate; male frons shining, with sub-
aciculate sparse rows of fine granules; female frons very finely punctured, with
moderately to very abundant, long, fine hair .......................................................... 11
11(10). Pronotum shining; declivity only slightly impressed; female frons feebly convex, with very fine, long, moderately abundant hair; Chiapas to Honduras; $1.8-2.0 \mathrm{~mm}$
9. maurus (Blandford)

- Pronotum partly reticulate in posterolateral areas; declivity rather strongly impressed; female frons slightly impressed, with abundant, long, rather coarse, yellow hair; Honduras to Costa Rica; 2.1-2.8 mm

10. costaricensis Schedl

12(6). Larger; interstrial setae on disc and lateral areas of declivity very fine, slender; vestiture on female frons long, sparse; male frons shallowly impressed, a low median elevation above upper level of eyes; Panama; $1.8-2.3 \mathrm{~mm}$
11. fulgidus Wood

- Smaller; interstrial setae on disc and declivity moderately to very coarse, slightly flattened, male frons evenly convex

13
13(12). Female frons convex, with a few minute granules, sparsely pubescent; elytral declivity leśs strongly, more narrowly impressed; Costa Rica; 1.5-1.7 mm
12. schedli Wood

- Female frons somewhat flattened, finely punctured, with abundant, long fine pubescence; elytral declivity more strongly, broadly impressed; Honduras to Costa Rica; 1.4-1.7 mm

13. vicinus Wood

14(5). Male declivity feebly, broadly impressed to broadly convex, frons strongly impressed and with a prominent median elevation on vertex; female declivity usually more strongly convex than male, frons moderately convex

- Male declivity broadly sulcate to rather strongly, broadly concave, male frons less strongly impressed, median elevation absent (except moderately to weakly developed in knausi); female declivity usually similarly but usually less strongly impressed, interstriae 1 never elevated; female frons variable but usually somewhat similar to male
15(14). Pronotal disc with coarse, subcrenulate granules, punctures obscurely evident only near median line, obsolete laterally; male frons below upper level of eyes almost flat, median elevation on vertex moderately developed, little if any higher at its lower end; Durango to Michoacán; $1.6-1.9 \mathrm{~mm}$............. 14. rudis Wood
- Pronotal disc with crenulations smaller, punctures clearly evident, obscure but usually present almost to lateral margins; male frons more strongly impressed, median elevation on vertex higher or projecting slightly at its lower end
16(15). Pronotal disc subreticulate between crenulations, crenulations shorter, thicker, less acutely elevated, more regularly spaced; male frontal impression not as deep, more extensive, elevation on vertex blunt; Panama; $1.5-2.0 \mathrm{~mm}$ $\qquad$ 15. confinis Wood
- Pronotal dise shining, crenulations longer, thinner, more acutely elevated, surface appearing more wrinkled; male frontal excavation deeper, less extensive, elevation on vertex acute; Utah and S California to Michoacán and Morelia; Cucurbita; $1.5-2.2 \mathrm{~mm}$

16. cucurbitae (LeConte)

17(14). Elytral declivity narrower, rather broadly bisulcate, sutural interstriae as
strongly elevated as lateral convexities; average size smaller ............................ 18

- Elytral declivity broad to very broad, moderately to very strongly impressed, lateral convexities distinctly higher than suture, interstriae 1 usually not elevated; average size larger

18(17). Pronotum rather strongly reticulate over entire surface, asperities on anterior half small, rather widely separated, punctures small, most of them subgranulate; interstrial setae rather coarse, blunt; Costa Rica; 1.5-1.8 mm 17. declivis Schedl

- Pronotum rather coarsely asperate and shining on anterior half, rather coarsely punctured or asperate and either shining or partly, obscurely reticulate on anterior half; interstrial setae more slender 19
19(18). Larger, stouter; pronotum 1.15 times as long as wide; pronotal and elytral punctures larger, deeper; discal striae as wide as interstriae; pronotum shining, entirely devoid of reticulation; declivital strial and interstrial punctures very small; female frons with moderately abundant pubescence; Guatemala; 2.3-2.5 mm

21. limbatus (Blandford)

- Smaller, more slender; pronotum 1.2 times as long as wide; pronotal and elytral punctures smaller; discal interstriae one and one-half times as wide as striae
20(19). Interstrial setae on disc longer, very fine, pointed, on declivity each seta one and one-half times as long as distance between rows, spaced within a row by distances half as great as between rows; strial setae in posterolateral areas fine, more than half as long as interstrial setae; body slender, 3.0 times as long as wide; Veracruz to Costa Rica $1.7-2.0 \mathrm{~mm}$

18. macilentus (Blandford)

- Interstrial setae about as on declivity, blunt, those on declivity as long as distance between rows, spaced within a row by distances slightly less than their length; strial setae very short, almost obsolete; body stouter, about 2.6 times as long as wide
21(20). Pronotum at least partly reticulate on posterior half in marginal areas or near punctures; transverse granules on pronotal dise finer, not reaching posterior margin; elytral punctures averaging slightly smaller; Veracruz and Honduras to Guadaloupe; $1.7-1.9 \mathrm{~mm}$ 19. guatemalensis (Hopkins)
- Pronotum shining, devoid of reticulation; transverse granules on pronotal disc coarser, more widely distributed; elytral punctures averaging slightly larger: Florida to Cuba and Jamaica; 1.6-1.7 mm ............................ 20. carbonarius (Ferrari)
22(17). Interstriae about as wide as striae, strial and interstrial punctures coarse, of equal size and spacing; pronotal disc shining, punctures coarse, deep; vestiture fine, very long; New Mexico and Kansas to Chihuahua; 1.7-2.3 mm

22. knausi (Hopkins)

- Interstriae about twice as wide as striae, punctures smaller, more widely spaced; pronotal disc at least partly reticulate in lateral areas, punctures smaller; vestiture much shorter; Honduras to Costa Rica; 2.0-2.9 mm

23. diversus Wood

## 1. Dendrocranulus consimilis Wood

Dendrocranulus consimilis Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):23 (Holotype, male; Los Corchos, Nayarit, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from limus Wood by the smaller size, by the more slender form, and by the shorter interstrial setae on the declivity.

Male.- Length $1.2-1.5 \mathrm{~mm}, 2.5$ times as long as wide; color yellowish brown.

Frons convex, with a slight transverse impression on lower half; surface shining, closely, deeply, rather coarsely punctured at sides and above, becoming almost impunctate on median fourth of lower half; vestiture of fine, sparse, long hair uniformly distributed.

Pronotum 1.2 times as long as wide, sides on more than posterior two-thirds subparallel, feebly arcuate, anterior margin broadly rounded; anterior third moderately
declivous, finely asperate, asperities decreasing in size but attaining base in lateral areas; disc shining, rather coarsely punctured, most punctures partly granulate; surface on posterior half very slightly subreticulate. Vestiture of sparse hair.

Elytra 1.6 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on more than basal two-thirds, abruptly, very broadly rounded behind; striae not impressed, punctures rather small; interstriae almost smooth, twice as wide as striae, punctures uniseriate, almost as large as those of striae. Declivity very steep, transversely flattened between interstriae 3, longitudinally slightly convex; posterolateral margin from suture to about interstriae 3 subacutely elevated; striae 1 and 2 distinctly impressed; interstriae 1 weakly elevated, 2 very slightly depressed, punctures of 2 and 3 finely granulate, obscurely granulate in lateral areas. Vestiture of rows of minute, obscure, recumbent, strial hair and rows of erect interstrial bristles; each bristle about one and one-third times as long as distance between rows or between bristles within a row, except shorter, slightly more than half as long on declivital interstriae 1 and 2.

Female.-Similar to male except frons more broadly, evenly convex, with frontal pubescence about twice as abundant.

Distribution.- Nayarit to Honduras.
MEX1CO: Nayarit: Los Corchos, $10-$ VII-65, 7 m , No. 207, climbing vine, S. L. Wood. HONDURAS: La Lima, $5-\mathrm{V}-64.200 \mathrm{~m}$, No. 579 in Cayaponia microdonta, No. 580 in Sicydum tamnifolium, S. L. Wood.

Hosts.-Cayaponia microdonta, Sicydum tamnifolium.

Biology.- Specimens were taken from broken stems of climbing vines.

Notes.- The above treatment was based on the type series of 42 specimens and on 8 other specimens.

## 2. Dendrocramulus limus Wood

Dendrocranulus limus Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):38 (Holotype, male; Rio Damitas in the Dota Mts.. San José, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from the closely allied tardus Schedl by the rather strongly convex elytral declivity, by the less strongly elevated posterolateral
margin of the declivity, and by the more widely spaced strial punctures.

Male.-Length 1.7-2.0 mm, 2.7 times as long as wide, color light reddish brown.

Frons weakly convex, surface reticulate and rather coarsely, not deeply punctured, reticulation and punctures reduced toward center on lower half; vestiture rather sparse, consisting of fine, long hair.

Pronotum 1.2 times as long as wide; sides of middle third almost straight and parallel, posterior angles broadly rounded, anterior angles arcuately converging toward broadly rounded anterior margin; dorsal profile arcuate from base, a little more strongly declivous on anterior third; surface shining, with few points, punctures rather coarse, deep, separated by distances equal to width of a puncture, lateral margin of each puncture very finely asperate, tubercles becoming larger laterally. Vestiture hairlike, inconspicwous except laterally and in asperate area.

Elytra 1.6 times as long as wide, 1.3 times as long as pronotum; sides straight and parallel on slightly more than basal two-thirds, broadly rounded behind, striae not impressed, punctures large, deep; interstriae slightly wider than striae, almost smooth, shining, punctures two-thirds as large as those of striae, spaced by one to two times diameter of a puncture. Declivity steep, distinctly convex; posterolateral margin acutely elevated from apex to interstriae 7; striae weakly impressed; interstriae weakly convex, punctures reduced and feebly granulate. Vestiture consisting of erect, interstrial bristles.

Female.-Similar to male except frons bearing a rather dense fringe of long, yellow hair to well above eyes, except central area glabrous.

Distribution.- Costa Rica.
COSTA RICA: Río Damitas, Dota Mts., San José, 18-$11-64,250 \mathrm{~m}$, No. 441, vine, and 447 Sechium cdule, S. L. Wood; Playón, Puntarenas, $22-\mathrm{II}-64,50 \mathrm{~m}$, No. 454, cucurbit vine, S. L. Wood.

Hosts.- Sechium edule, etc.
Notes. - The above treatment was based on the type series of 43 specimens.

## 3. Dendrocranulus tardulus Wood

Dendrocranulus tardulus Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):37 (Holotype, male; Río Damitas in the Dota Mts., San José, Costa Rica; Wood Coll.)

Diagnosis.- This species is distinguished from tardus Schedl by the smaller size, by the smaller, less strongly impressed pronotal punctures, and by the shorter costa on the posterolateral margin of the declivity.

Male.- Length $1.4-1.5 \mathrm{~mm}, 3.0$ times as long as wide; color light brown.

Frons convex above eyes, rather shallowly, transversely impressed below; surface shining, closely, subgranulately punctured; vestiture very fine, long, rather sparse, hairlike.

Pronotum 1.2 times as long as wide; widest just behind middle, sides moderately arcuate, rather broadly rounded in front; summit indefinite, well in front of middle; surface almost smooth, with a few minute points, punctures on dise rather coarse, close, separated by distances about equal to their diameters, becoming somewhat finely asperate in lateral areas. Vestiture consisting of rather sparse, erect hair.

Elytra 1.6 times as long as wide, 1.3 times as long as pronotum; sides almost straight and feebly dilated on basal two-thirds, then slightly narrowed to just before apex, and abruptly rounded to very broadly rounded, almost straight posterior margin; striae not impressed, punctures rather large, deep; interstriae slightly wider than striae, smooth and shining, punctures almost as large and deep as those of striae, separated by distances about equal to twice diameter of a puncture. Declivity steep, almost flat; posterolateral margin subacutely elevated from apex to interstriae 7 , interstriae 2 almost flat, impressed, 1 and area lateral to 2 moderately elevated; strial and interstrial punctures somewhat smaller than on disc, those of interstriae very finely granulate. Vestiture consisting of erect, blunt, rather long, interstrial bristles.

Female.- Similar to male except frons evenly convex and more closely pubescent; declivital interstriae 2 feebly if at all impressed, weakly convex, 1 and lateral areas less strongly elevated; vestiture finer.

Distribution.- Costa Rica.
costa rica: Río Damitas, Dota Mts., San José, 18 -II-64, 250 m , No. 448 in a vine, No. 447 in Sechium edule, S. L. Wood.

Notes.- The above treatment was based on the type series of 12 specimens and on 25 other specimens.

## 4. Dendrocranulus tardus Schedl

Dendrocranulus tardus Schedl, 1937, Arch. Instit. Biol. Veg. Río de Janeiro 3:165 (Holotype, female?; La Caja, 8 km W San José, Costa Rica; Schedl Coll.)
Diagnosis.- This species is distinguished from tardulus Wood by the larger size, by the larger, deeper pronotal punctures, and by the longer costa on the ventrolateral margin of the elytral declivity.

Male.- Length $1.9-2.0 \mathrm{~mm}, 2.6$ times as long as wide; color reddish brown.

Frons as in tardulus except more nearly granulate. Pronotum as in tardulus except punctures on disc larger, closer, deeper, those in lateral areas each with a lateral subcrenulate granule.

Elytra as in tardulus except strial punctures slightly larger, deeper; declivity more broadly flattened, posterolateral margin subacutely elevated from suture to interstriae 7, a lower pseudocosta associated with it on 5 and 6 , strial punctures larger, deeper.
Female.- Essentially as in male.
Distribution. - Honduras to Costa Rica.
honduras: la Lima, Cortéz, 5-V-64, 200 m . No. 579, Cayaponia macrodonta, S. L. Wood. COSTA RICA: La Caja, 8 km W San José, San José.
Host.- Cayaponia macrodonta.
Note.- The above treatment was based on a male in my collection that was compared directly to the female holotype. The holotype is 1.90 mm long, the male 2.05 mm .

## 5. Dendrocranulus pumilus Wood

Dendrocranulus pumilus Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):38 (Holotype, male; Río Damitas in the Dota Mts., San José, Costa Rica: Wood Coll.)
Diagnosis.- This species superficially resembles consimilis Wood, but it is distinguished by the absence of an acute ventrolateral margin of the elytral declivity, by the larger strial punctures, and by the absence of granules on the pronotal disc.

Male.- Length $1.3-1.4 \mathrm{~mm}, 2.7$ times as long as wide; color yellowish brown.

Frons convex, a slight transverse impression on lower half; surface obscurely reticulate, punctures fine, with small granules; vestiture sparse, hairlike.

Pronotum 1.2 times as long as wide; widest just behind middle, sides feebly arcuate, converging very slightly anteriorly, anterior
margin rather broadly rounded; finely asperate on anterior fourth; surface subreticulate, punctures rather coarse, close, not at all granulate. Vestiture hairlike, confined to areas near margins.

Elytra 1.9 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal two-thirds, then gradually narrowed to broadly rounded posterior margin; striae not impressed, punctures coarse, deep; interstriae equal to or slightly narrower than striae, punctures about two-thirds as large as those of striae and slightly less abundant. Declivity steep, flattened between striae 3; strial punctures almost as large and as deep as on disc; interstriae 1 moderately elevated, 2 impressed (at least medially), gradually ascending laterally to interstriae 3 ; interstrial punctures less abundant than on dise, not at all granulate. Vestiture consisting of rows of erect interstrial bristles.

Female.- Similar to male except frontal impression feebly developed; elytral declivity weakly, more narrowly impressed.
Distribution.- Costa Rica.
costa rica: Río Damitas, Dota Mts., San José, 18-11-64, 250 m , No. 446, vine, S. L. Wood.

Notes.- The above treatment was based on the holotype and allotype and on 13 other specimens.

## 6. Dendrocranulus vinealis Wood

Dendrocranulus vinealis Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):24 (Holotype, male; La Lima, Cortéz, Honduras; Wood Coll.)
Diagnosis.- This species is distinguished from the closely allied pumilus Wood by the shining pronotal disc, by the subcrenulate granules accompanying each puncture on the pronotal dise, and by the much more strongly impressed male frons.

Male.-Length 1.2-1.3 mm, 2.7 times as long as wide; color very dark brown.

Frons convex above upper level of eyes, strongly, transversely impressed below that level; surface smooth and shining, with moderately fine, subgranulate punctures in convex area, almost impunctate in impressed area; vestiture of sparse hair.

Pronotum outline as in pumilus, anterior area more coarsely asperate; surface shining, punctures moderately coarse, deep, rather close, each with a low lateral, subcrenulate,
transverse granule. Vestiture confined to margins, sparse, hairlike.

Elytra outline about as in pumilus; striae not impressed, punctures small, moderately deep; interstriae smooth, twice as wide as striae, punctures slightly smaller than those of striae, rather widely spaced. Declivity steep, rather broadly flattened; strial punctures deeper, slightly larger than on disc, interstriae 1 weakly elevated, 2 weakly depressed, punctures not at all granulate; ventrolateral margin rounded. Vestiture of interstrial rows of flattened bristles, each bristle slightly longer than distance between rows or within a row.
Distribution.- Honduras.
honduras: La Lima, Cortéz, 5-V-64, 200 m , No. 579, Cayaponia microdonta, S. L. Wood.

Biology. - As described for the genus.
Notes.- The above treatment was based on the type series of 2 male specimens.

## 7. Dendrocranulus vicinalis Wood

Dendrocranulus vicinalis Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):24 (Holotype, male; Rio Damitas, Dota Mts., San José, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from vinealis Wood by the much smaller strial and interstrial punctures, by the more gradual elytral declivity, and by the interstrial granules on the declivity.

Male.- Length $1.5-1.7 \mathrm{~mm}, 2.9$ times as long as wide, color yellowish brown.

Frons as in vinealis except impression not as abrupt, impunctate area much smaller, small granules more conspicuous in lateral areas. Pronotum as in vinealis except discal punctures slightly smaller, granules not as slender. Elytra as in vinealis except strial and interstrial punctures smaller, very shallow; punctures on declivital interstriae $1-3$ replaced by small granules.

Female.- Similar to male except frontal impression not as strong, sculpture finer, vestiture finer, more abundant but not as conspicuous.

Distribution.- Costa Rica.
COSTA RICA: Rio Damitas, Dota Mts., San José, 18-II-64, 250 m , Nos. 440, 441, climbing vine, S. L. Wood.

Notes.- The above treatment was based on the type series of three specimens.

## 8. Dendrocranulus securus Wood

Dendrocranulus securus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):25 (Holotype, male; Río Damitas. Dota Mts., San José, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from maurus (Blandford) by the partly reticulate posterolateral areas of the pronotum, by the reticulate, more finely punctured frons, and by the shorter, stout setae on declivital interstriae 1 and 2 .

Male. - Length $1.7-2.1 \mathrm{~mm}, 2.5$ times as long as wide; color reddish brown.

Frons convex, a shallow, transverse impression from epistoma to upper level of eyes; surface reticulate, punctures moderately fine, deep, close, not at all granulate, less abundant near median line on lower half; vestiture sparse, hairlike.

Pronotum 1.1 times as long as wide; widest well behind middle, sides moderately arcuate on posterior half, feebly constricted one-third length from anterior margin, anterior margin rather narrowly rounded; asperities small, abundant; surface of disc and lateral areas subreticulate, punctures rather small, deep, a low, transverse, rounded granule lateral to each puncture. Vestiture fine, sparse, hairlike.

Elytra 1.5 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on less than basal two-thirds, posterior margin straight on median half; striae not impressed, punctures rather small, deep, close; interstriae almost smooth, twice as wide as striae, punctures fine, uniseriate, rather widely, regularly spaced. Declivity steep; striae 1 weakly impressed; interstriae 1 weakly elevated; interstrial punctures minutely granulate; central half flattened, broadly convex in all marginal areas as in maurus. Vestiture of rows of minute, recumbent, strial hair, and rows of erect interstrial bristles; each bristle almost as long as distance between rows and between bristles within a row, slightly shorter and coarser than in maurus.

Female. - Similar to male except frontal impression less distinct, vestiture very slightly more abundant.

## Distribution.- Costa Rica.

COSTA RICA: Río Damitas, Dota Mts., San José, 18-II-64, 250 m , No. 446, vine, S. L. Wood; Playón, Puntarenas, $22-\mathrm{II}-64,50 \mathrm{~m}$, Nos. 454, 455, vine, S. L. Wood;

Turrialba, Cartago, 9-III-64, 700 m , No. 460, vine, S. L. Wood.
Notes.- The above treatment was based on the type series of 28 specimens.

## 9. Dendrocranulus maurus (Blandford)

Dryocoetes maurus Blandford, 1898, Biol. Centr. Amer., Coleopt. $4(6): 191$ (Holotype, female; El Tumbador, San Marcos, Guatemala; British Mus. Nat. Hist.)
Dendrocranulus huehuetanus Schedl, 1940, An. Esc. Nac. Cienc. Biol., Mexico 1:344 (Lectotype, male; Huehuetán, Chiapas, Mexico; Schedl Coll., designated by Wood, 1974, Great Basin Nat. 34:280). Synonymy
Diagnosis.- This species is distinguished from the very closely allied securus Wood by the shining, more granulate frons, by the complete absence of reticulation on the pronotum, and by the slightly longer, more slender interstrial setae.

Male.- Length $1.8-2.0 \mathrm{~mm}, 2.6$ times as long as wide; color dark brown.

Frons as in securus except transverse impression slightly deeper, surface smooth, shining, punctures in lateral areas finely granulate. Pronotum as in securus except entirely devoid of reticulation. Elytra as in securus except interstrial granules on declivity very slightly larger; elytral bristles finer, distinctly longer.

Female.- Similar to male except frons planoconvex, finely punctured, with pubescence fine, long, much more abundant.

Distribution.- Chiapas to Honduras.
MEXICO: Chiapas: Huehuetán. Veracruz: 13 km N Sontecomapan, 20-V1-69, J. M. Campbell. GUATEMALA: El Tumbador, San Marcos, G. C. Champion. HONDURAS: La Lima, Cortéz, 5-V-64, 200 m , No. 579 , Cayaponia microdonta, S. L. Wood.

Host.- Cayaponia microdonta.
Notes.- The above treatment was based on the holotypes of maurus and huehuetanus and on seven other specimens that were compared directly to the type.

## 10. Dendrocranulus costaricensis Schedl

Dendrocranulus costaricensis Schedl, 1939, Archiv Naturgesch. 7:171 (Holotype, male; Turrialba, Cartago, Costa Rica; Eggers, Coll., apparently on loan to Sched!)
Diagnosis.- This species is distinguished from the very closely related maurus (Blandford) by the larger size, by the reticulation on
the posterolateral areas of the pronotum, by the more strongly impressed elytral declivity, and by the more abundant frontal vestiture of the female.

Male.- Length 2.1-2.8 mm, 2.6 times as long as wide; color yellowish to reddish brown.

Frons as in maurus except summit on median area of vertex not as high. Pronotum as in maurus except granules on median discal area smaller, and posterolateral areas partly reticulate. Elytra as in maurus except declivity more strongly impressed in central area; on declivity sutural interstriae moderately elevated, striae 1 and median side of interstriae 2 impressed, gradually ascending to striae 3. Vestiture as in securus but slightly shorter on declivity.

Female.-Similár to male except frons planoconvex, with a tuft of abundant, long, yellow hair from epistoma to vertex.

Distribution.- Honduras to Costa Rica.
honduras: La Lima, Cortéz, 5-V-64, 200 m , No. 579. Cayaponia microdonta. COSTA RICA: Puerto Viejo, Heredia, 12-III-64, 70 m . No. 483, vine: Río Damitas, Dota M1ts., San José, 18-II-64, 250 m , Nos. 440, 446, 448 , vines; Playón, Puntarenas, 22--II-64, 50 m, No. 455 , cucurlit vine; Pandora, Limón, 23-VIII-63, 50 m , No. I48, cucurbit vine. All by me.

Hosts.- Cayaponia microdonta, etc.
Notes. - The above treatment was based on Schedl's male holotype of costaricensis and on 103 other specimens. Although the holotype was to have been deposited in the Eggers Collection, according to the original description, it is in the Schedl Collection, apparently on loan.

## 11. Dendrocranulus fulgidus Wood

Dendrocranulus fulgidus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):25 (Holotype, male; Volcán de Chiriquí, near Cerro Punta, Chiriquí, Panama: Wood Coll.)
Diagnosis.- This species is distinguished from the closely allied maurus (Blandford) by the discal granules on the pronotum, by the narrower elytral declivity, by the more strongly impressed male frons, and by the more coarsely punctured female frons, with less abundant vestiture.

Male.- Length 1.8-2.3 mm, 2.8 times as long as wide; color dark reddish brown, elytra lighter.

Frons as in maurus except transverse impression distinctly deeper, median summit on
vertex slightly higher. Pronotum as in maurus except granules extend to impunctate median line; posterolateral areas reticulate. Elytra as in maurus except more slender, declivity narrower, strial punctures much smaller, not as deep, interstriae 2 more distinctly impressed, surface brightly shining; granules as in maurus; declivital setae on interstriae 1 and 2 very short, less than half as long as on 3 or on disc.
Female.-Similar to male except frons planoconvex, more coarsely punctured on lateral thirds than in female maurus, vestiture fine, long, slightly less abundant than in female maurus.

Distribution.- Panama.
PANAMA: Cerro Punta, Chiriquí, Panama, II-I-64, 1800 m , Nos. $378,408,418$, cucurbit vine, S. L. Wood.

Notes. - The above treatment was based on the type series of 99 specimens.

## 12. Dendrocranulus schedli Wood

Dendrocranulus cucurbitae Schedl, 1939 (nec. LeConte, 1879), Arb. Morph. Tax. Ent. Berlin-Dahlem 6:45 (Syntypes: Hamburgfarm on Rio Raventazón, Limón, Costa Rica; Deutschen Ent. Inst. and Schedl Coll.)
Dendrocranulus schedli Wood, 1966, Great Basin Nat. 26:23 (Replacement name)
Diagnosis.- This species is almost indistinguishable from vicinus Wood except for secondary sexual characters on the frons. In this species the male frons is distinctly, transversely impressed on the lower half; the female frons lacks this impression and the frontal vestiture is sparse. In vicinus the male frons is as the female frons of schedli and the female frons is somewhat flattened, rather coarsely punctured, and with a brush of abundant, fine, hairlike setae.

Male.- Length $1.5-1.7 \mathrm{~mm}, 3.0$ times as long as wide; color yellowish to reddish brown.

Frons convex, moderately, transversely impressed on lower half; surface shining, punctures rather fine, moderately deep, finely granulate, somewhat more finely sculptured in median half of impressed area; vestiture of sparse, long hair.

Pronotum 1.2 times as long as wide; sides almost straight and parallel on basal half, rather broadly rounded in front; rather finely asperate on anterior third, changing to low, oval, rounded granules and extending to base;
some granules near median line accompanied by small, deep punctures; surface shining. Vestiture confined to marginal areas, sparse.

Elytra 1.9 times as long as wide; sides almost straight and parallel on basal threefourths, rather broadly rounded behind; striae not impressed, punctures small, moderately deep; interstriae almost smooth, twice as wide as striae, punctures about half as large as those of striae. Declivity rather steep, narrowly flattened; striae 1 and 2 weakly impressed, interstrial punctures replaced by fine granules, interstriae 2 weakly impressed; marginal areas broadly convex. Vestiture of rows of fine, very short, recumbent strial hair, and rows of erect, interstrial bristles; each bristle slightly longer than distance between rows or between bristles within a row, each very slightly flattened on its apical half.

Female.- Similar to male except transverse frontal impression absent.
Distribution.- Costa Rica.
COSTA RICA: Río Damitas, Dota Mits., San José, is-II-64, 250 m , No. 440, vine, S. L. Wood; Turrialla, Cartago, 9-1II-64, 700 m , No. 458, vine, S. L. Wood.

Notes.- The above treatment was based on my male that was compared to Schedl's male syntype and on 14 other specimens.

## 13. Dendrocranulus vicinus Wood

Dendrocranulus vicinus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):25 (Holotype, female; La Lima, Cortéz, Honduras; Wood Coll.)
Diagnosis.-See the diagnosis of schedli Wood, above, and the following description.

Male.- Length $1.4-1.7 \mathrm{~mm}, 3.0$ times as long as wide; color yellowish to reddish brown.

Frons as in female schedli. Pronotum as in schedli except granules in median area of disc slightly larger and evidently never associated with punctures. Elytra as in schedli except striae 1 and 2 and interstriae 2 usually less strongly impressed.

Female.-Similar to male except frons more broadly convex, more closely punctured, punctures not at all granulate, ornamented by a tuft of long, fine, abundant, yellow hair.

Distribution. - Honduras to Costa Rica.
HONDURAS: La Lima, Cortéz, 5-V-64, 200 m , No. 579, Cayaponia microdonta, S. L. Wood; La Ceiba. Atlántida, 29-V-49, at light, E. C. Becker. COSTA RICA: Tapantí, Cartago, 17-VIII-63, 1300 m , No. 103,

Polakoushia tacaco, S. L. Wood; Turrialba, Cartago, 9-III-64, 700 m , No. 458, cucurbit vine, S. L. Wood; Pandora, Limón, 23-V1HI-63, 50 m , No. I48, cucurbit vine, S . L. Wood.

Hosts.- Cayaponia microdonta, Polakowskia tacaco, etc.

Notes.- The above treatment was based on the type series of 26 specimens and on 5 other specimens.

This species is virtually identical to schedli except for the secondary sexual characters of the frons. Because both were taken from the same vine, No. 548, at Cartago, it indicates that sibling species or else dimorphic females of one species are represented. One female of vicinus and seven specimens of schedli were in that sample.

## 14. Dendrocranulus rudis Wood

Dcndrocranulus rudis Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):26 (Holotype. male; 19 km E Carapan, Michoacán, Mexico; Wood Coll.)
Diagnosis.- This species is allied to cucurbitae (LeConte), but it is distinguished by the slightly larger rugae on the pronotal dise, with the punctures obscure to obsolete, and by the less deeply excavated male frons with the median elevation on the vertex less well developed.

Male.- Length $1.6-1.9 \mathrm{~mm}, 2.8$ times as long as wide; color very dark brown.

Frons somewhat flattened, transversely impressed from epistoma to upper level of eyes, weakly ascending above; median elevation on summit rather well developed, highest at its dorsal extremity, gradually descending below; surface smooth, with an occasional fine puncture or minute granule; vestiture sparse, hairlike.

Pronotum 1.2 times as long as wide; widest just behind middle, sides rather strongly arcuate on posterior two-thirds, rather narrowly rounded in front; anterior third rather coarsely asperate, low, transverse crenulations continuing to base, some crenulations in median area associated with obscure punctures. Vestiture fine, long, moderately abundant.

Elytra 1.7 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal three-fourths, very broadly rounded behind; striae not impressed, punctures rather small, moderately impressed,
spaced by about two diameters of a puncture; interstriae smooth, twice as wide as striae, equal in size and spacing to those of striae. Declivity steep, broadly flattened; striae 1 and 2 feebly impressed; interstriae 1 weakly elevated, 2 weakly impressed, lateral areas about as high as suture; interstrial punctures not granulate. Vestiture of rows of fine, short, recumbent strial hair, and rows of erect interstrial bristles; each bristle rather slender, about one and one-fourth times as long as distance between rows, slightly shorter on declivital interstriae 1 and 2 .

Female.-Similar to male except frons rather coarsely punctate-granulate, granules mostly arranged in rugae, vertex devoid of median elevation; declivity more nearly convex, impressions and elevations obscure.
Distribution.- Durango to Michoacán.
MESICO: Durango: 5 km W El Salto, 7-VI-65, 2600 m, No. 32, cucurbit vine, S. L. Wood. Michoacán: 19 km E Carapan, I8-VI-65, 2300 m , No. 75 , cucurbit vine, S. L. Wood.

Notes.- The above treatment was based on the type series of 53 specimens.

## 15. Dendrocranulus confinis Wood

Dendrocranulus confinis Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):26 (Holotype, male; Volcán de Chiriqui, Chiriquí, Panama; Wood Coll.)
Diagnosis.- This species is distinguished from the very closely related cucurbitae (LeConte) by the subreticulate pronotal surface between crenulations on the disc, and by the slightly shallower, more extensive frontal excavation of the male.

Male.- Length $1.5-2.0 \mathrm{~mm}, 2.7$ times as long as wide; color very dark reddish brown, pronotum black in some specimens.

Frons as in cucurbitae but very slightly less strongly excavated, impression extending higher in lateral areas, median projection on vertex equal in size. Pronotum as in cucurbitae except discal punctures slightly larger, surface subreticulate, evidently less irregular. Elytra as in cucurbitae except discal punctures very slightly larger.

Female.-Similar to male except frons broadly convex, a slight transverse impression just above epistoma; surface subreticulate, punctures rather small, shallow, vestiture sparse; declivity more evenly convex, interstriae 2 not as strongly impressed.

Distribution.- Panama.
Panama: Volcán de Chiriquí, near Cerro Punta, Chiriquí, 11-I-64, 1800 m , No. 378, cucurbit vine, S. L. Wood.
Notes.- The above treatment was based on the type series of 40 specimens.

## 16. Dendrocranulus cucurbitae (LeConte)

 Fig. 172Xylocleptes cucurbitae LeConte, 1879, Bull. U.S. Geol. Survey 5:519 (Holotype, female; Utah; Mus. Comp. Zool.)
Xylocleptes californicus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:44 (Holotype, female; Pomona, California; U.S. Nat. Mus., 7610); Wood, 1973, Great Basin Nat. 33:176. Synonymy
Xylocleptes venturina Hopkins, 1915, U.S. Dept. Agric. Rept. 99:44 (Holotype, female; Ventura Co., California: U.S. Nat. Mus., 7611); Wood, 1973, Great Basin Nat. 33:176. Synonymy
Xylocleptes punctatus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:44 (Holotype, female; Mesilla, New Mexico; U.S. Nat. Mus., 7421); Wood, 1973, Great Basin Nat. 33:176. Synonymy
Diagnosis.- This species is distinguished from confinis Wood by the more deeply, less extensively excavated male frons, with the median elevation on the vertex more acute, by the absence of reticulation on the pronotal disc, and by other characters noted in the above treatment of confinis.

Male.- Length $1.5-2.2 \mathrm{~mm}, 2.7$ times as long as wide; color very dark brown.

Frons transversely excavated from emarginate epistomal margin to well above upper level of eyes, convex on vertex, with median area of vertex acutely elevated at upper margin of excavation; surface of excavated area smooth, brightly shining, almost impunctate; glabrous except at margins.

Pronotum as in rudis except punctures larger, deeper, crenulations smaller; devoid of reticulation.

Elytra as in rudis except strial punctures slightly larger, declivity flatter; vestiture similar but very slightly longer.

Distribution.- New Mexico, S Utah, and S California to Morelia.

USA: Arizona: Bonita. California: Azusa, Desert Center, Laguna, Martinez, Newton, P.fmona Mts., Pasadena, Playa del Rey, Sierra Madre, Ventura Co. New Mexico: Mesilla. Utah: St. George. MEXICO: Chihuahua: 100 km NE Meoqui. Mexico: San Miguel Tlaixpan, 4-I-80, Sechium edulis, T. H. Atkinson. Michoacán: Lombardia, 1-X1-80, S-141, Luffa acutangula, T. H. Atkinson. Morelia: Cuernavaca, 6-XII-79, T. H. Atkinson.

Hosts.-Cucurbita digitata, C. foctidissima, Echinocystis macrocarpa, Luffa acutangula.

Notes.- The above treatment was based on the holotypes of cucurbitae, californicus, venturina, and punctatus and on 169 other specimens.

## 17. Dendrocranulus declivis Schedl

Dendrocranulus dectivis Schedl, 1937, Arch. Instit. Biol. Veg. Río de Janeiro 3:166 (Holotype, female: Turrialloa. Cartago. Costa Rica; Schedl Coll.)
Diagnosis. - The broadly impressed, subconcave male elytral declivity and the reticulate pronotal dise distinguish this species from the preceding species.

Male.- Length 1.5-1.8 mm, 2.7 times as long as wide; color very dark brown.

Frons broadly convex, with a slight transverse impression between epistoma and upper level of eyes; surface almost smooth, punctures moderately coarse, obscurely arranged into subaciculate rows except central third impunctate; vestiture sparse, hairlike.

Pronotum 1.1 times as long as wide; widest near base, sides rather weakly arcuately con-
verging to rather narrowly rounded anterior margin; asperities on anterior third very small; posterior areas reticulate, finely punctured, a minute granule associated with each puncture. Vestiture sparse, fine, hairlike.

Elytra 1.6 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal two-thirds, broadly rounded behind; striae not impressed, punctures rather small, moderately deep, close; interstriae smooth, twice as wide as striae, punctures small, uniseriate. Declivity rather steep, broadly, subconcavely impressed; interstriae 1 weakly elevated, 2 broadly impressed, lateral areas gradually ascending to 4,4 very slightly higher than 1 , lateral elevations continued toward suture near apex; punctures on interstriae 2 and upper part of 3 replaced by small granules. Vestiture of rows of very fine, recumbent, short, strial hair, and rows of erect, interstrial bristles; each bristle about as lorg as distance between rows or between bristles within a row.

Female.- Similar to male except frontal impression poorly developed, impunctate area greatly reduced in size; elytral declivity

Fig. 172. Dendrocranulus cucurbitac: 1, anterior half of male; 2, female protibia; 3, female antenna; 4, male declivity.
narrower, impression not as deep, interstrial granules smaller, some obsolete.

Distribution.- Costa Rica.
COSTA RICA: Río Damitas, Dota Mts., San José, 18 -II-64, 250 m , No. 427, Sechium edule; Tapantí, Cartago, 17-VIII-63, I300 m, No. 103, Potakowskia tacaco; Turrialba, Cartago, 9-III-64, 700 m , No. 457, Sechium edule; Guápiles, Limón, 22-VIII-66, 100 m , No. 114, cucurbit vine; Pandora, Limón, 23-VIlI-63, 50 m , No. 148, cucurbit vine; all by me.

Hosts.- Potakowskia tacaco, Sechium edule, etc.

Notes. - The above treatment was based on the holotype and on 84 other specimens.

## 18. Dendrocranulus macilentus (Blandford)

Dryococtes macilentus Blandford, 1898, Biol. Centr. Amer., Coleopt. 4(6):190 (Lectotype, female: Jalapa, Veracruz, Mexico; British Mus. Nat. Hist., designated by Wood, 1973, Great Basin Nat. 33:176)
Dendrocramulus grossopunctatus Schedl, 1937, Arch. Instit. Biol. Veg. Río de Janeiro 3:166 (Holotype, female; San lsidro de Coronado. San José, Costa Rica; Schedl Coll.); Wood, 1973. Great Basin Nat. 33:176. Synonymy
Diagnosis.- Only the female is known. It is distinguished by the very slender body form and by the fine, long interstrial setae.

Female.- Length $1.7-2.0 \mathrm{~mm}, 3.0-3.1$ times as long as wide; color very dark brown, almost black.

Frons about as in male declivis, except transverse impression stronger.

Pronotum 1.25 times as long as wide; widest just behind middle, sides weakly arcuate on posterior two-thirds, rather narrowly rounded in front; anterior third rather coarsely asperate, rather finely, deeply punctured in discal area, each puncture associated with a small, low, rounded, transverse granule, these granules much larger in lateral areas. Vestiture of fine, moderately long hair, much more abundant than in allied species.

Elytra 1.85 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal three-fourths, broadly rounded; striae not impressed, punctures small, moderately deep; interstriae twice as wide as striae, smooth, punctures uniseriate, almost as large as those of striae. Declivity essentially as in female declivis except strial punctures slightly larger, deeper, interstriae 2 more distinctly impressed, interstrial granules obsolete. Interstrial setae very slender, at
least one and one-half times as long as distance between rows.

Distribution.- Veracruz and Costa Rica.
MEXICO: Veracruz: Jalapa, Hoege. COSTA RICA: San Isidro de Coronado, San José, 17-I-29, 1400-1500 m, F. Nevermann; Tapantí, Cartago, 24-X-63, 1300 m , No. 244 vine, S. L. Wood.

Notes. - The above treatment was based on the lectotype of macilentus, on the holotype of grossopunctatus, and on my female that was compared to both types. All three specimens are females of an unusually slender form. The strial punctures are very slightly smaller in my specimen than in the specimens of Blandford and Schedl. Until additional material is available, including males, that provides characters for distinguishing two populations these names will be considered synonyms.

## 19. Dendrocranulus guatemalensis (Hopkins)

Xylocleptes guatemalensis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:44 (Holotype, female; Panzos, Guatemala; U.S. Nat. Mus., 7612)
Dendrocranulus parallelus Schedl, 1938, Archiv Naturgesch. 7:172 (Holotype, sex?; Trois Riviéres, Guadeloupe; U.S. Nat. Mus., 60.353); Wood, 1976, Great Basin Nat. 36:348. Synonymy
Diagnosis.- This species is somewhat similar to rudis Wood, but it is distinguished by the less extensively impressed male frons, with the summit on the vertex higher but more broadly rounded, by the punctured pronotal disc, and by the more strongly impressed elytral declivity.

Male.- Length $1.7-1.9 \mathrm{~mm}, 2.9$ times as long as wide; color very dark brown.

Frons transversely impressed on lower half, almost flat on median half of lower half, surface smooth and shining on impressed area, impunctate except laterally, -subreticulate and rather coarsely punctured on convex area; summit on vertex broadly rounded, moderately high.

Pronotum as in confinis Wood except gramules in discal area greatly reduced, surface brightly shining. Elytra as in declivis Schedl.

Female.-Similar to male except frons convex, impression obscure; elytral declivity less strongly impressed.

Distribution.- Veracruz to Honduras and Guadeloupe 1sland.

MEXICO: Veracruz: Lago Catemaco: 16-VI-69, D. E. Bright. HONDURAS: La Lima, Cortez, 5-V-64, 200 m , No. 579. Cayaponia microdonta, S. L. Wood: La Ceiba, Atlantida, 20-V-49, at light, E. C. Becker. CUADELOUPE. Trois Riviéres.

Host.- Cayaponia microdonta.
Notes. - The above treatment was based on my female that was compared to the type of parallelus, on the holotype of quatemalensis, and on eight other specimens.

## 20. Dendrocranulus carbonarius (Ferrari)

Xyloclcptes carbonarius Ferrari, I867, Die Forst- und Baumzuctschädlichen Borkenkäfer, p. 41 (Holotype, male; Cuba; Vienna Mus.)
Xiylocleptes floridensis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:43 (Holotype, female; Biscayne Bay, Florida; U.S. Nat. Mus.); Wood, I973, Creat Ba$\sin$ Nat. 33:176. Synonymy
Xylocleptes anonae Hopkins, 1915, U.S. Dept. Agric. Rept. 99:43 (Holotype, female; Florida; U.S. Nat. Mus.): Wood, 197:3, Great Basin Nat. 33:176. Synonymy
Diagnosis.- This species is distinguished from quatemalensis (Hopkins) by the much less strongly impressed male frons, which bears fine granules and whose summit on the vertex is broadly rounded, by the larger granules of the pronotal dise, and by the slightly larger punctures on the elytral declivity.

Male.- Length $1.6-1.7 \mathrm{~mm}, 2.8$ times as long as wide; color very dark brown.

Frons shallowly, transversely impressed on lower half, broadly convex above, without a definite elevation on vertex; surface shining, with isolated, moderately close granules in impressed area, intermixed with punctures above; vestiture sparse.

Pronotum about as in confinis Wood except reticulation absent. Elytra as in quatomalensis except declivital punctures slightly larger, deeper, granules obsolete.

Female.- Similar to male except frons more evenly convex, granules largely replaced by punctures.

Distribution.-S Florida to Cuba and Jamaica.

USA: Florida: Biscayne Bay, 17-V, Hubbard and Schwarz; "Florida," I4-V, Anona (error?), E. A. Schwarz. CUBA: Cayamas, 3-II, E. A. Schwarz. JAMAICA: Bright (pers. comm.) saw specimens from Porus, 23-II-37, Chapin and Blackwelder (at the U.S. Nat. Mus.).
Notes.- The above treatment was based on the holotypes of carbonarius, floridensis, and anonae and on 12 other specimens.

Hopkins reported one series of this species from Anona. Because this genus occurs exclusively in Cucurbitaceae, Hopkins's host record must have been accidental or in error.

## 21. Dendrocranulus limbatus (Blandford)

Dryocoetes limhatus Blandford, I898, Biol. Centr. Amer.. Coleopt. 4 6 ):190 (Lectotype, male; Volcán de Agua, Guatemala: British Mus, Nat. Hist., present designation)
Diagnosis.- This species is distinguished from macilentus (Blandford) and quatemalensis (Hopkins) by the larger size, by the stouter, more coarsely punctured pronotum, by the strial punctures being coarse on the elytral disc but very fine on the declivity, and by the moderately pubescent female frons.

Male.- Length 2.3-2.5 mm, 2.6 times as long as wide; color very dark brown, elytra dark reddish brown.

Frons of lectotype visible only to upper level of eyes, almost flat, epistomal margin very weakly elevated; surface smooth, shining, with very small, isolated, setiferous granules uniformly distributed; vestiture of fine, moderately long, uniformly distributed hair.

Pronotum 1.15 times as long as wide; widest slightly behind middle, sides moderately arcuate, converging on anterior third, rather narrowly rounded in front; indefinite summit on basal third; anterior half rather coarsely asperate; posterior third coarsely, deeply punctured, with transverse lines between punctures accompanied by weak calluses; surface shining, with no indication of reticulation. Vestiture of fine long hair.

Elytra 1.6 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal two-thirds, slightly narrowed, then very broadly rounded behind; striae not impressed, punctures rather coarse, deep; interstriae smooth, shining, very slightly wider than striae, punctures deep, coarse, superficially appearing almost as large as those of striae. Declivity steep, flat, longitudinally, very feebly concave transversely; impression extending to median area of interstriae 3, interstriae 1 weakly elevated, 2 impressed, 3 slightly higher than 1 ; strial punctures greatly reduced, minute on lower half of 1 , interstrial punctures very minutely granulate; lateral margins rounded. Vestiture
of fine, long interstrial setae; shorter on declivity, setae about as long as distance between rows (except largely obsolete on 2 ).

Female.- Similar to male except granules on frons slightly larger, frontal vestiture more abundant, longer, particularly on upper half; declivital impression not as distinct.

Distribution.-Guatemala.
GUatemala; Volcán de Agua, $8500-10500 \mathrm{ft}$ $(2600)-3200 \mathrm{~m})$, G. C. Champion.

Notes.- The above treatment was based on four of five syntypes remaining in the British Museum (Natural History). The first of these four syntypes is here designated as the lectotype of limbatus Blandford.

## 22. Dendrocranulus knausi (Hopkins)

Xylocleptes knausi Hopkins, I915, U.S. Dept. Agric. Rept. 99:44 (Holotype, female; Ashland, Kansas; U.S. National Mus., 7613)

Diagnosis.- This species has the male elytral declivity much more strongly, broadly impressed than any of the preceding species; it differs from diversus Wood by the larger strial and interstrial punctures, which are subequal in size to one another, and by other characters summarized in the above key.

Male.- Length $1.7-2.3 \mathrm{~mm}, 2.5$ times as long as wide; color dark reddish brown.

Frons rather strongly, transversely impressed from epistoma to upper level of eyes; upper area convex, with subaciculate rugae to upper margin of impressed area, impressed area mostly smooth, shining, a few small granules and a short, indefinite, subcarinate, median, longitudinal elevation just above epistoma; summit on vertex, with a short, rather strongly elevated, median carina; vestiture sparse.

Pronotum 1.2 times as long as wide; widest well behind middle, sides on posterior twothirds rather sharply arcuate, a weak constriction on anterior third, rather narrowly rounded in front; finely asperate on anterior third, rather coarsely, deeply punctured behind, each puncture bearing a minute granule on its lateral margin. Vestiture of fine, long, moderately abundant hair.

Elytra 1.8 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal three-fourths, very broadly rounded to subemarginate behind; strial punctures coarse, deep; interstriae as wide as
striae, smooth, punctures almost as large as those of striae and equally spaced. Declivity steep, broadly, shallowly concave; sutural interstriae weakly elevated, 2 impressed, ascending laterally to 4 , at 4 distinctly higher than at suture; punctures slightly smaller than on disc, devoid of granules. Vestiture of fine, long, hair, each two or more times as long as distance between interstrial rows, about half as long on declivity.

Female.- Similar to male except frontal impression and elevations less well developed, surface granulate-punctate to epistoma; elytral declivity more narrowly, less strongly impressed, interstriae 1 less distinctly elevated.

Distribution.- New Mexico and Kansas to Chihuahua.

USA: Kansas: 5 miles ( 8 km ) S Waldo, Russell Co., 1952; Ashland, 8-V-08, wild gourd, W. Knaus; Garden City, Chittenden no. 2429. New Mexico: $8 \mathrm{mi}(13 \mathrm{~km})$ NE Portales, 30-ViI-53, Cucurbita, S. L. Wood. Oklahoma: Woodward, 30-V11-53, Cucurbita, S. L. Wood; "Oklahoma," 27-III-67, pumpkin stems, C. E. Langston. MEXICO: Chihuahua: 40 km SE Chihuahua, 27-VII-53, Cucurbita, S. L. Wood.

Hosts.- Cucurbita pepo, C. sp.
Notes.- The above treatment was based on the holotype of knausi and on 21 other specimens.

## 23. Dendrocranulus diversus Wood

Dendrocranulus ditersus Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):37 (Holotype, male; Puerto Viejo, Limón, Costa Rica; Wood Coll.)
Male.- Length $2.0-2.9 \mathrm{~mm}, 2.5$ times as long as wide; color very dark brown.

Frons convex above eyes, rather strongly, transversely impressed from upper level of eyes to epistoma; epistomal margin broadly emarginate, upper tooth on mandibles projecting anteriorly and partly filling this emargination; surface reticulate almost to epistomal margin, rather closely, deeply punctured, many punctures granulate; vestiture consisting of rather long, sparse hair.

Pronotum 1.1 times as long as wide; widest just behind middle, sides strongly arcuate from base to rather narrowly rounded anterior margin; posterior surface almost smooth and shining, punctures moderately large, deep, close, each puncture with a very minute lateral granule (almost imperceptible at
center), granules increasing in size laterally. Vestiture bristlelike, almost entirely limited to lateral and asperate areas.

Elytra 1.3 times as long as wide, 1.2 times as long as pronotum; sides arcuately narrowed from level of declivital base to level of sutural apex, posterior margin straight or feebly, broadly emarginate over about twothirds of elytral width; striae I feebly, others not impressed, punctures small, close, rather deep; interstriae about twice as wide as striae, surface obscurely etched by minute points and lines, punctures slightly smaller than those of striae and about half as numerous. Declivity rather abrupt, steep, broadly, shallowly concave; posterolateral margin obtusely rounded, strongly elevated from apex to interstriae 4 , conspicuously higher than 1 ; interstriae 1 weakly elevated, 2 wider and impressed, all interstriae with a median row of fine granules; striae 1,2 , and 3 with punctures rather strongly impressed. Vestiture consisting of interstrial rows of erect bristles.

Female.- Similar to male except frons less strongly impressed, granules reduced, more strongly reticulate; elytral declivity narrower, less strongly impressed.

Distribution.-Honduras to Costa Rica.
HONDURAS: La Lima, 5-V-64, 200 m , No. 5:9. Cayaponia microdonta. COSTA RICA: Puerto Viejo, Limón, 12-111-64, 70 m , No. 483, vine; Pandora, Limón, 23-VIII-63, 50 m , No. 148, vine; Turrialba, Cartago, 9-III-64, 700 m , No. 460, vine; Rio Damitas, Dota Mts., San José, 18-II-64, 250 m , No. 446, vine; Playón, Puntarenas, 22-11-64, 50 m , No. 459, cucurbit vine. All taken by me.

Hosts.- Cayaponia microdonta, etc.
Notes. - The above treatment was based on the type series of 39 specimens and 11 other specimens.

## Genus DR YOCOETES Eichhoff

Anodius Motschulsky, 1860, in Schrenck, Reisen und Forschungen in Amur-Lande 2:155 (Type-species: Bostrichus autographus Ratzeburg, subsequent designation by Wood, 1974, Bull. Zool. Nomencl. 31:232); Internat. Comm. Zool. Nomencl., 1979, Bull. Zool. Nomencl. 36:149. Name suppressed
Dryococtes Eichhoff, 1864, Berliner Ent. Zeitschr. 8:38 (Type-species: Bostrichus autographus Ratzeburg, subsequent designation by Hopkins, 1914, Proc. U.S. Nat. Mus. 48:121); Internat. Comm. Zool.

Nomencl., 1979, Bull. Zool. Nomencl, 36:149. Name conserved
Dryococtinus Balachousky, 1949, Faune de France 50:180 (Type-species: Bostrichus villosus Fabricius, original designation); Schedl, 1958. Tidj. Ent. 101:143. Synonymy
Diagnosis. - In the North American fauna this genus is distinct and easily recognized by antennal, tibial, and elytral characters presented in the key to genera, and by the exceedingly broad oral region.

Description.- Length 1.7-4.4 mm, 2.3-2.6 times as long as wide: color dark reddish brown.

Frons broadly convex, punctate to granulate: vestiture hairlike, rather sparse except moderately to exceedingly dense in females of some species; oral region unusually broad. Eye oval, emarginate. Antennal scape elongate; funicle 5 -segmented, club obliquely truncate, basal area corneous. Pronotum 1.0-1.3 times as long as wide, rather evenly arched from anterior to posterior margin; anterior area finely to coarsely asperate, asperities reaching base laterally in most species, reaching median area in some. Elytra weakly to strongly striate, declivity convex to flattened, conservatively sculptured. Vestiture hairlike. Meso- and metathoracic tibiae rather slender, abruptly narrowed on less than apical one-fifth, armed on lateral and apical margins by three to seven socketed teeth.

Distribution.- North America, Asia, Europe, and Africa: about 90 species have been named, although most of them have been transferred to other genera; 7 species occur in North America.

Biology. - The lower bole of standing, unthrifty trees is usually selected for attack, except betulae evidently prefers limbs of its host. The beetles are polygynous and phloeophagous, with the parental galleries of a radiate type that do not score the wood. Larval mines are entirely in the phloem, rather short, and wander indiscriminantly. Evidently from one to two years is required to complete a life cycle. They may pass the winter as larvae or adults. Parent adults may produce more than one brood.

Notes.- This genus apparently originated in the eastern hemisphere and migrated to North America in comparatively recent
geologic times. The hosts of all seven North American species are typical of the northern coniferous forest. With the exception of sechelti and caryi each species is more closely related to an Asian species than to any American species. One species, autographus, is considered to be the same species on
both continents, although minute anatomical differences are evident.

Several closely related groups that occur in Africa and in the Indo-Malayan region are doubtfully distinct from Dryocoetes. A thorough worldwide study of the Dryocoetini is needed.

## Key to the Species of Dryococtes <br> (Modified from Bright [963)

1. Larger, 2.8-4.4 mm; pronotum widest at or near middle, sides rather strongly arcuate, 1.0-1.1 times as long as wide

- $\quad$ Smaller, $1.7-3.1 \mathrm{~mm}$; pronotum either widest at base or sides weakly arcuate, subparallel, 1.1-1.3 times as long as wide4

2(1). Female frons sparsely pubescent, small median area smooth, impunctate; male frons more sparsely pubescent, surface distinctly granulate; elytral declivity almost evenly convex, interstriae 1 very feebly elevated; pronotum rather finely asperate on anterior half and sides, disc rather coarsely, deeply punctured; spruce forests of North America south to New Mexico and North Carolina, etc.; Picea, Pinus, etc.; 2.8-4.4 mm 1. autographus (Ratzeburg)

- Female frons with dense, conspicuous pubescence; elytral declivity steeper, interstriae 1 distinctly elevated, 2 broadly impressed; pronotum rather coarsely asperate over more than anterior half
3(2). Female frons very finely granulate, vestiture moderately dense, very fine, shortest setae on lower half twice as long as width of eye, longer above; disc on posterior third of pronotum punctured; discal interstriae less than twice as wide as striae, strial punctures coarse, punctures on interstriae 3 uniseriate; British Columbia and Newfoundland to Louisiana and Florida; Betula, rarely other hosts; 2.8-3.8 mm

2. betulae Hopkins

- Female frons densely, finely punctured, not at all granulate, vestiture dense, fine, longest setae about equal in length to width of eye, shorter below; pronotum asperate or subasperate to base; discal interstriae about three times as wide as striae, strial punctures rather small, punctures on interstriae 3 confused; British Columbia and Alberta to Arizona and New Mexico; Abies lasiocarpa, rare in other Abies and Picea; 3.2-4.3 mm

3. confusus Swaine

4(I). Declivital striae 1 deeply impressed, punctures large, deep, decliwital interstriae 1 strongly elevated, uniseriately granulate; discal striae wider than interstriae, strial punctures coarse, deep; pronotum 1.2-1.3 times as long as wide, with sides parallel on basal two-thirds; Quebec to Arkansas and North Carolina; Picea; 2.2-2.4 mm
4. granicollis (LeConte)

- Declivital striae 1 impression and punctures about as on 2, declivital interstriae 1 only slightly elevated, granules feebly developed or absent; discal striae distinctly wider than interstriae, strial punctures smaller, not as deep; pronotum 1.1-1.2 times as long as wide, widest behind middle 5
5(4). Female frons with moderately long, abundant pubescence, male frons sparsely pubescent; declivity more strongly flattened; pronotum less strongly arched along median line, disc more finely punctured, granules appearing smaller and more widely spaced; Alaska and New Mexico to Newfoundland and North Carolina; Picea, rarely other hosts; 2.3-3.1 mm

5. affaber (Mannerheim)

- Female frons only slightly more pubescent than male; elytral declivity more strongly convex on longitudinal axis; pronotal disc more coarsely punctured, granules appearing closer, slightly larger, general surface of disc on some specimens appearing subgranulate; smaller
6(5). Interstriae on disc twice as wide as striae, striae 1 on declivity weakly impressed, its punctures small, rather shallow, declivital interstriae 1 weakly elevated; British Columbia and Montana to Utah and Colorado; Abies lasiocarpa; $1.6-2.2 \mathrm{~mm}$

6. sechelti Swaine

- Interstriae on disc as wide as striae, striae 1 on declivity impressed, its punctures rather coarse, deep, declivital interstriae 1 distinctly elevated; Alaska and Quebec to Wyoming and North Carolina; Picea; 1.9-2.3 mm $\qquad$ 7. caryi Hopkins

## 1. Dryocoetes autographus (Ratzeburg) Fig. 173

Bostrichus autographus Ratzehurg, 18.37. Die Forstinsekten 1:160 (Syntypes; presumably Cermany; apparently lost with the Hamburg Musemm)
Dryocoetes autographus: Eichhoff, 1864. Berliner Ent. Zeitschr. 8:39
Bostrichus septentrionis Mannerheim, 1843, Moskov. Obshch. Isp. Prirody, Otd. Biol. Biul. (Bull. Soc. Imp. Nat. Moscou) 16(2):298 (reprint p. 126) (Syntypes; Sitka Island, Alaska; lost') not at Itelsinki Mus.); Eichhoff, 1876, Stett. Ent. Zeit. 37:378 (Synonymy); Bright, 1963, Ann. Ent. Soc. Amer. 56:108. Synonymy
Bostrichus semicastenetus Mannerheim, 1852, Moskov. Obshch. lsp. Prirody, Otd. Biol. Biul. (Bull. Soc. Imp. Nat. Moscou) 25(2):358 (reprint p. 76) (Holotype, sex?: Sitka Island, Alaska; Helsiuki Mus.); LeConte, 186s, Trans. Amer. Ent. Soc. 2:161. Synonymy
Bostrichus victoris Mulsant and Rey, 1853, Opusc. Ent. 2:91 (Syntypes?; Faillefen, Basses Alpes, France; not located): Bedel, 1888, Ann. Soc. Ent. France, hors serie, 6:416. Synonymy
Dryococtes americanus Hophins, 1915, U.S. Dept. Agric. Rept. 99:51 (Holotype, female; Cheat Bridge, Randolph County, West Virginia; U.S. Nat. Mus., 7632): Bright, 196:3, Ann. Ent. Soc. Americ. 56:108. Synonymy
Dryocoetes pseudotsugue Swaine, 1915, Canadian Ent. 47:360 (reprint p. 5) (Lectotype, female; Stanles Park, Vancouver Island, British Cohmbia; Canadian Nat. Coll., 9293, designated by Bright, 1967, Canadian Ent. 99:674): Bright, 1963, Ann. Ent. Soc. Amer. 56:108. Synonymy
Diagnosis.- This species is distinguished from other American representatives of the genus by the larger size, by the punctured, nonasperate pronotal disc, by the more evenly convex elytral declivity, and by the sculpture and vestiture of the female frons.

Male.-Length $2.8-4.4 \mathrm{~mm}, 2.5$ times as long as wide; color rather dark reddish brown.

Frons broadly convex from epistoma to vertex; surface smooth, shining, with moderately coarse, rather close, deep punctures, their margins feebly granulate at least in lateral areas; vestiture of very sparse, long hair; epistomal brush wide, conspicuous.

Pronotum 1.1 times as long as wide; widest at middle, sides evenly, strongly arcuate from base to rather narrowly rounded anterior margin; anterior two-fifths and lateral areas to base finely asperate, remaining area coarsely, deeply, closely punctured; a smooth, shining, impunctate median line on posterior half usually present. Vestiture confined to marginal areas, of long hair.

Elytra 1.6 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, punctures rather coarse, deep; interstriae smooth, shining, as wide as striae, punctures moderately fine, deep, uniseriate. Declivity steep, broadly convex; sculpture about as on disc; interstrial punctures finely granulate or not; interstriae 1 feebly elevated. Vestiture of rows of fine, short, strial hair; and rows of much longer, rather fine, interstrial hair.

Female.- Similar to male except frons with a weak, transverse impression just below middle (variable), impunctate at center, remaining area with sparse granules; interstrial punctures on declivity finely granulate.

Distribution. - North American coniferous forests south to New Mexico and North Carolina, and northern Europe and Asia.

ALASKA: Numerous localities. CANADA: Alberta, British Columbia, Labrador, Manitoba. New Brunswick, Newfoundland, Northwest Territories, Quebec,

Fig. 173. Dryocoetes spp., pronotum, antenna, and male genitalia: 1, 7, granicollis; 2, 4, 8, affaber; 3, 11, autographus; 5, caryi; 6, sechelti; 9, betulae; 10, confusus. (After Bright 1963:112.)

Saskatchewan, Yukon Territory. USA: Califormia, Colorado, Idaho, Maine, Michigan, Mimesota, Montana, Nevada, New Hampshire, New Mexico, New York, North Carolina, Oregon, Pennsylvania, South Dakota, Tennessee, Utah, Virginia, Washington, West Virginia, Wisconsin, Wyoming.

Hosts.- Abies sp., Picea engelmannii, $P$. glauca, Pinus contorta, P. monticola, P. strobus, Pseudotsuga menziesii, Tsuga heterophylla.

Biology.- Essentially as described for the genus. They occur most commonly in the stumps and large roots of standing, dying trees.
Notes.- The syntypes of autographus evidently were destroyed. The above treatment was based on specimens compared by Eggers to them prior to their destruction, on a Mannerheim female of septentrionis in the Canadian National Collection, on the holotypes of semicastaneus and americanus, and on the lectotype of pseudotsugae. The Mannerheim collection does not contain a specimen of septentrionis. Because Mannerheim regarded it as only a variety of semicastaneus, it is possible that the type was sent to LeConte because his 1852 treatment of the species lists LeConte, not Mannerheim, as its author. In all, 1,107 American and 35 European specimens were examined.

The American specimens tend to have the frons more sparsely granulate, the strial punctures slightly larger and not as deep, and the elytral declivity slightly more convex than the European material. The differences are slight, variable, and not suitable for statistical analysis; therefore, I prefer to follow Bright (1963) and recognize only one species.

## 2. Dryococtes betulae Hopkins

Fig. 173
Dryocoetes eichhoffi Hopkins, 1894 (nec. Ferrari, 1867), Canadian Ent. $26: 279$ (reprint p. 5) (Syntypes; evidently eastern United States; U.S. Nat. Mus.)
Dryocoetes betulae Hopkins, 1915, U.S. Dept. Agric. Rept. 99:50 (Holotype, female; Grant County, Virginia; U.S. Nat. Mus., 7630). Replacement name
Dryocoetes liquidambaris Hopkins, 1915, U.S. Dept. Agric. Rept. 99:51 (Holotype, female; Virginia Beach, Virginia; U.S. Nat. Mus., 7631); Blackman, 1922, Mississippi Agric. Expt. Sta. Tech. Bull. 11:120. Synonymy
Diagnosis.- This species is distinguished from autographus (Ratzeburg) by the more
finely, more closely granulate male frons, by the very different sculpture and pubescence of the female frons, by the more coarsely and extensively asperate pronotum, and by the more strongly impressed elytral declivity, with the interstrial granules much more conspicuous.

Male.- Length 2.8-3.8 mm, 2.4 times as long as wide; color dark reddish brown.

Frons sexually dimorphic; male as in autographus except much more closely granulate.

Pronotum 1.06 times as long as wide; as in autographus except widest slightly behind middle, asperities larger, asperate area extending two-thirds of pronotum length from anterior margin in median area, to base in lateral areas.

Elytra 1.6 times as long as wide, 1.6 times as long as pronotum; as in autographus except declivity more flattened due to interstriae 2 being broadly, moderately impressed, 1 distinctly and 3 feebly elevated; declivital interstrial granules distinctly larger.

Female.- Similar to male except frons less strongly convex, surface finely, very closely granulate, punctures not evident, ornamented by a rather dense brush of fine, long hair from epistoma to vertex, length of hair near epistoma twice as long as width of eye, three times as long near vertex.

Distribution.- British Columbia and Newfoundland to Louisiana and Florida.

CANADA: Alberta, British Columbia, Newfoundland, New Brunswick, Ontario, Quebec. USA: District of Columbia, Florida, Louisiana, Maine, Michigan, Mississippi, Montana, New Hampshire, New Jersey, New York, North Carolina, Pennsylvania, Virginia, Vermont, West Virginia, Washington.

Hosts.- Betula lenta, B. lutea, B. papyrifera; less common in Fagus grandifolia, Liquidambar styraciflua, etc.

Biology.- Essentially as described for the genus. It may attack stumps and the bole and limbs of recently cut and unthrifty trees.

Notes.- The above treatment was based on the holotypes of betulae and liquidambaris and on 344 other specimens.

## 3. Dryocoetes confusus Swaine <br> Fig. 173

Dryocoetes confusus Swaine, 1912, Canadian Ent. 44:351 (Holotype, female; Colorado, 18, Cornell U. lot 302, sub. 35; Cornell Univ. Coll.)

Dryofoetes abietis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:52 (Holotype, female; Lake MacDonald, Montana; U.S. Nat. Mus., 7628); Swaine, 1918. Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(2):131. Synonymy
Diagnosis.- This species is distinguished from the closely allied betulae by the much smaller strial punctures, by the strongly confused punctures on discal interstriae 3, and by the finely, densely punctured female frons, with a more dense, shorter brush of hair.

Male.- Length $3.2-4.3 \mathrm{~mm}, 2.3$ times as long as wide; color rather dark reddish brown.

Frons much as in autographus but not as wide, punctures smaller, almost devoid of granules; mandibles not as elongate.

Pronotum 1.1 times as long as wide; as in betulae except asperate area extending to base in median area.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; striae 1 feebly, others not impressed, punctures small, deep; interstriae smooth, shining, three to four times as wide as striae, punctures deep, only slightly smaller than those of striae, moderately confused on 2, strongly confused on 3. Declivity essentially as in betulae except interstriae 2 slightly more strongly impressed, 1 more strongly elevated; granules moderately coarse.

Female.- Similar to male except frons weakly convex, surface densely, very finely punctured, devoid of granules, vestiture of dense brush of reddish hair, hair length near epistoma slightly shorter than width of eye, distinctly longer near vertex.

Distribution.- British Columbia and Alberta to Arizona and New Mexico.

CANADA: Alberta: Jasper Park, Lesser Slave Lake. British Columbia: Hope Summit, Lorna, Mt. Apex, Stanley Park, Terrace, Trinity Valley. USA: Arizona: Flagstaff, San Francisco Mts. Colorado: Aspen, Newcastle, Norwood, Rabbit Ears Pass, Ridgeway, Rifle. Idaho: Coeur d'Alene, Lakeview, Riggins. Montana: Big Hole Co., Glacier, Phillipsburg. New Mexico: Coyote, Sandia Mts. Oregon: Gold Lake in Willamette N.F., Silver Creek, Sumpter, Tollgate. Utah: Brighton, Cedar Breaks N.M., La Sal Mts., Logan Canyon, Logan Dry Canyon, Manti N.F., Mirror Lake in Summit Co., Monticello. Wyoming: Wapati, Yellowstone N.P.

Hosts.-Abies lasiocarpa; less commonly in A. amabilis, A. concolor, and Picea engelmannii.

Biology.- Essentially as described for the genus. The lower bole of standing trees is usually selected for attack. Evidently this species is moderately aggressive and capable of killing overmature or unthrifty trees. Most commonly the attack is made on one side or area of the bole, then successive generations girdle the remaining area over more than one season. Less commonly, cut or fallen trees are attacked by this species.

Notes. - The above treatment was based on the holotypes of confusus and abietis and on 318 other specimens.

## 4. Dryococtes granicollis (LeConte) Fig. 173

Xyleborus granicollis LeConte, 1868, Trans. Amer. Ent. Soc. 2:162 (Holotype, sex?; Sullivan County, Pennsylvania; Mus. Comp. Zool., 1018)
Dryocoetes granicollis: LeConte, 1876, Proc. Amer. Philos. Soc. 15:643
Diagnosis.- This species is distinguished from the allied sechelti Swaine and caryi Hopkins by the elongate pronotum that has straight subparallel sides, by the very strongly impressed dechivital striae 2 that have unusually large punctures, and by the strongly elevated, subserrate declivital interstriae 2.

Male.-Length $2.2-2.4 \mathrm{~mm}, 2.6$ times as long as wide; color reddish brown.

Frons broadly convex above, almost flat below; surface obscurely reticulate, finely granulate-punctate; vestiture sparse, fine, long.

Pronotum 1.2 (female 1.3) times as long as wide; sides almost straight and parallel on basal two-thirds; rather finely asperate on anterior two-thirds and sides, fine punctures subasperate on posterior discal area. Vestiture fine, hairlike, long on marginal areas, short on disc.

Elytra 1.6 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal three-fourths, very broadly rounded behind; striae distinctly, others feebly if at all impressed, punctures very coarse, deep; interstriae slightly narrower than striae, smooth, shining, punctures fine, uniseriate, a few of them obscurely subgranulate. Declivity steep, bisulcate; striae 1 very deeply, broadly impressed, punctures unusually large, much larger than on other striae; interstriae 1 rather abruptly, strongly
elevated, its height about equal to 2 and 3, each interstriae with a uniseriate row of fine granules. Vestiture of rows of fine, short, strial hair; and rows of much longer, rather coarse, interstrial hair.

Female.- Similar to male except frons with pubescence more abundant (about twice that of male), pronotum more elongate, and declivital granules distinctly larger.

Distribution.- Quebec to Arkansas and North Carolina.

CANADA: Quebec: Chelsea, Gaspé. USA: Arkansas: Senton Co. District of Columbia: Washington. Kentucky: Noble. Louisiana: Tallulah. Missouri: Dent Co. New Jersey: Orange Mt. New York: Jamaica. North Carolina: Tryon. Ohio: Wooster. Pennsylvania: Arendtsville, Germantown, Pen Mar, Suilivan Co. Virginia: Falls Church, Grover Camp.

Hosts.- Picea glauca, etc.
Biology.- Evidently as described for the genus. Specimens were removed from the lower bole of a small dying spruce about 20 cm in diameter. Castanca and Juglans have been recorded as hosts, but these records have not been confirmed.

Notes.- The above treatment was based on the holotype and on 56 other specimens.

## 5. Dryocoetes affaber (Mannerheim) Figs. 173. 174

Bostrichus affaber Mannerheim, 1552, Moskor. Obshch Isp. Prirody, Otd. Biol. Biul. (Bull. Soc. Imp. Nat. Moscow) $25(2): 359$ (reprint, p. 77) (Holotype, female; Sitka Island, Alaska: Helsinki Mus.)
Dryococtes affaber: LeConte, 1876, Proc. Amer. Philos. Soc. 15:361
Dryococtes pubescens Swaine, 1912, Canadian Ent. 4:350 (Holotype, female; Colorado, Cornell U. lot 302, sub. 37; Canadian Nat. Coll., 9291); Bright, 1963, Ann. Ent. Soc. Amer. 56:111. Synonymy
Dryocoetes piceae Hopkins, 1915, U.S. Dept. Agric. Rept. 99:51 (Holotype, female; Cranesville, West Virginia: U.S. Nat. Mus., 7627); Bright. 1963, Ann. Ent. Soc. Amer. 56:111. Synonymy
Diagnosis.- Contrary to what might be expected from the above key, this species is much more closely allied to confusus Swaine than to other American species, but it is distinguished by the smaller size, by the uniseriate punctures on discal interstriae 3, by the less strongly impressed elytral declivity, and by the different vestiture on the female frons. It is much more closely allied to pini Niijima, from Japan.

Male.- Length 2.3-3.1 mm, 2.6 times as long as wide; color yellowish to reddish brown.

Frons as in granicollis LeConte.
Pronotum 1.1 times as long as wide; essentially as in confusus.

Elytra 1.6 times as long as wide, 1.6 times as long as pronotum; outline as in granicollis; striae not impressed, punctures small, deep; interstriae smooth, shining, twice as wide as striae, punctures slightly smaller than those of striae, rather deep, uniseriate. Declivity steep, very broadly convex; interstriae 2 weakly impressed, 1 moderately elevated; interstrial granules rather small. Vestiture essentially as in confusus.

Female.- Similar to male except frons finely, closely punctured, with a moderately dense brush of rather long hair from epistoma to vertex, each hair slightly greater in length than width of eye; declivital interstriae 2 less strongly impressed, 1 less strongly elevated.

Distribution.- Alaska and Newfoundland to New Mexico and North Carolina.

ALASKA: Numerous localities. CANADA: Alberta, British Columbia, Manitoba, Newfoundland, New Brunswick, Ontario, Quebec, Saskatchewan, Yukon Territory. USA: Arizona (Hannagan Camp, Greenlee Co.), Colorado, Idaho, Maine, Michigan, Minnesota, New Hampshire, New Mexico, New York, North Carolina, Oregon, Pennsylvania, Utah, South Dakota, Tennessee, Washington, W'est V'irginia, W'isconsin.

Fig. 174. Dryocoetes affaber, female. (After Swaine 1925:pl. VI.)

Hosts. - Picea engelmannii, P. glauca, P. mariana, P. rubra, P. sitchensis; rare in Abies fraseri, Pinus monticola, P. strobus, and other conifers.

Biology.- Essentially as described for the genus. This species attacks unthrifty, cut, fallen, and injured trees, particularly the lower bole, but stumps and limbs are also infested.

Notes. - The above treatment was based on the holotypes of affaber, pubescens, and piceae, and on 1,709 other specimens.

## 6. Dryocoetes sechelti Swaine Fig. 173

Dryocoetes scchelti Swaine, 1915, Canadian Ent. 47:359 (Lectotype, female?; Sechelt, British Columbia, Canadian Nat. Coll., 9292, designated by Bright, 1967, Canadian Ent. 99:674.)
Diagnosis.- This species is distinguished from the very closely allied caryi Hopkins by the narrower discal striae and by the weakly impressed declivital interstriae 1 with its much smaller punctures.

Male.- Length $1.6-2.2 \mathrm{~mm}, 2.6$ times as long as wide; color reddish brown.

Frons broadly convex, with median line obtusely elevated on lower half; surface obscurely subreticulate, rather coarsely, deeply punctured; vestiture of fine, sparse, long hair.

Pronotum 1.1 times as long as wide; widest near base, sides weakly arcuate, converging slightly toward rather narrowly rounded anterior margin; finely asperate to base, rather coarse punctures intermixed with small asperities on median area on basal third. Vestiture of moderately abundant, fine, long hair.

Elytra 1.7 times as long as wide, 1.6 times as long as pronotum; outline as in affaber (Mannerheim); striae 1 weakly, others not impressed, punctures rather small, deep; interstriae smooth, shining, twice as wide as striae, punctures two-thirds as large as those of striae, deep, uniseriate. Declivity steep, broadly convex; interstriae 1 moderately elevated; striae 1 normal, similar to 2 ; interstrial punctures feebly granulate toward base. Vestiture as in other species, of rows of strial and interstrial hair.

Female.- Similar to male except frontal vestiture slightly more abundant; declivital interstrial granules very slightly larger and more widely distributed.

Distribution.-British Columbia and Montana to Utah and Colorado.
CANADA: British Columbia: Lorna, 3-VII-24, Abies lasiocarpa, R. Hopping; Sechelt. USA: Colorado: Newcastle, I-VIII-44, Picea engelmannii, C. L. Massey; Uncompagre N.F., 13-VIII-54, P. engelmannii, R. Sluss. Montana: Glacier N.P., 23-VIII-23, J. C. Evenden; West Yellowstone, 12-VII-72, G. Lasch. Oregon: Santiam Pass, 19-VII-46, Pinus contorta (accidental?), S. L. Wood; Suttle Lake, 1-VIII, Abies lasiocarpa. Utah: Geyser Pass in La Sal Mts., $300 \mathrm{~m}, \mathrm{~V}$. M. Tanner; Logan Canyon, 24 -VII-46. A. lasiocarpa, S. L. Wood; Logan Dry Canyon, 16-VI-46, A. lasiocarpa, S. L. Wood.

Hosts.- Abies lasiocarpa.
Biology.- Essentially as described for the genus. Specimens were taken from the lower bole of standing, dying trees $20-25 \mathrm{~cm}$ in diameter.

Notes.- The above treatment was based on the lectotype of sechelti and on 47 other specimens.

## 7. Dryocoetes caryi Hopkins

Fig. 173
Dryocoetes caryi Hopkins, 1915, U.S. Dept. Agric. Rept. 99:50 (Holotype, male; Camp Caribou, Maine; U.S. Nat. Mus., 7629)

Diagnosis.- This species is distinguished from sechelti Swaine as indicated in the above diagnosis and from granicollis (LeConte) by the stouter pronotum, by the slightly smaller strial punctures, by the less strongly impressed striae 1 with smaller punctures, and by the less strongly elevated interstriae 1.

Male.- Length $1.9-2.3 \mathrm{~mm}, 2.6$ times as long as wide; color reddish brown.

Frons and pronotum as in sechelti. Elytra as in sechelti except strial punctures larger; discal interstriae as wide as striae; declivital striae 1 very slightly deeper than 2 , its punctures slightly larger than those of 2 ; declivital granules slightly larger.

Female.- Similar to male except frontal vestiture very slightly more abundant; granules on elytral declivity slightly larger.

Distribution.-Alaska and Quebec to Wyoming and North Carolina.

ALASKA: Homer, 25-Vll-45, Picea, J. C. Chamberlin; Seward, 31-VIII-56, Picea lutzii, G. L. Downing. CANADA: Alberta: Crowsnest, 3-VII-51, No. A2039, $P$. glauca. British Columbia: Lorna, 3-VII-24, P. engelmannii, R. Hopping; Trinity Valley, 4-VII-54, P. engelmannii. Quebec: Chelsea, 17-V-54, P. glauca, S. L. Wood; Gaspé, 12-VIII-32, P. glauca, E. B. Watson. USA:

Maine: Caribou, 25-V-00, Picea, A. Cary; Maine Agricultural Experiment Station, 10-IX-14, M. W. Blackman. New York: Cranberry Lake, 25-VI-15, M. W. Blackman. North Carolina: Cherokee, 19-V11-51, P. rubra, S. L. Wood. Wyoming: Laramie, 8-VIII-47, P. B. Lawson.

Hosts.-Picea engelmannii, P. glauca, and P. rubra.

Biology.-As in sechelti.
Notes. - The above treatment was based on the holotype and on the 36 other specimens. Variations in this species and in sechelti are such that when more material is available for study it may become necessary to place the name sechelti in synonymy.

## Genus CoCCOTR ypes Eichhoff

Coccotrypes Eichhoff, 1878, Mém. Soc. Roy. Sci. Liége (2)8:57, 308 (Type-species: Bostrichus dactyliperda Fabricius, subsequent designation by Hopkins, 1914, Proc. U.S. Nat. Mus. 48:118)
Peocilips Schaufuss, 1897, Berliner Ent. Zeitschr. 42:110 (Type-species: Poccilips sannio Schaufuss, monobasic); Wood, 1973, Great Basin Nat. 33:171. Synonymy
Cryphaloides Formenek, 1908, Ent. Blät. 4:91 (Typespecies: Cryphaloides donisthorpei Formenek = Bostrichus carpophagus Hornung, monobasic); Schedl, 1962, Mitt. Münchner Ent. Ges. 52:95. Synonymy
Thammurgides Hopkins, 1915, U.S. Dept. Agric. Rept. 99:45 (Type-species: Thammargides persicae IIopkins = Coccotrypes advena Blandford, original designation); Schedl, 1938, Ent. Berichten 10:9. Synonymy
Spermatoplex Hopkins, 1915, U.S. Dept. Agric. Rept. 99:48 (Type-species: Spermatoplex rhizophorae Hopkins, original designation); Schedl, 1952, Ent. Blätt. 47-48:160. Synonymy
Dendrurgus Eggers, 1923, Zool. Meded. 7:144 (Typespecies: Dendrurgus rhizophorae Eggers $=$ Spermatoplex rhizophorae Hopkins, present designation); Eggers, 1927, Treubia 9:390. Synonymy
Diagnosis.- This genus is distinguished from Dryocoetes Eichhoff by the less extensive corneous part of the antennal club, by the more gradual, more narrowly convex elytral declivity, by the convergently aciculate frons, by the pronounced sexual dimorphism, and by the habits.

Description.- Length $1.2-2.5 \mathrm{~mm}$, 2.1-2.5 times as long as wide; color reddish brown to almost black; pronounced sexual dimorphism, males much smaller, deformed, flightless.

Frons broadly convex, convergently aciculate; vestiture sparse, hairlike. Eye elongate,
shallowly emarginate; finely granulate. Antennal scape elongate; funicle 5 -segmented; club more or less obliquely truncate, with or without sutures on posterior face. Pronotum variable, weakly to strongly arched, asperate to smooth. Elytra smooth, shining, striate; declivity convex, simple. Tibiae moderately slender, essentially as in Dryocoetes.

Distribution.- Essentially circumtropical, but transported through commerce to all parts of the world; more than a hundred nominate species exist in the literature, but there is a great deal of synonymy and confusion of names; eight occur in North and Central America.

Biology. - Most species infest large seeds, although a few forms are phloeophagous. The females mate with sibling males in the brood tunnels then emerge to seek a new host. The female enters the seed and constructs a short cave-type tunnel in which eggs are deposited in clusters. Larval development is very rapid. The larvae usually extend or enlarge the parental tunnel, often consuming the entire contents of the seed. Evidently more than one generation can develop in one fruit. Some species are exclusively phloeophagous and apparently many other spermophagous species can survive periods of stress in bark.

Notes.-Coccotrypes and Poecilips have been recognized as separate genera on the basis of the sculpture and degree of convexity of the pronotum. The extremes within the group are strikingly different from one another in general appearance as well as in habits; however, the variation is so great and intergradation between the groups is so complete I see no hope of recognizing more than one genus on either a morphological or biological basis. The literature indicates considerable confusion among taxonomists as to the generic placement of their species. The only possible means of separating them I see is the presence or absence of strial hair; in other groups this is not a reliable character.

Most of the American species have been introduced from the Eastern Hemisphere, and I suspect, when the world fauna is thoroughly known, all of them will fall into this category.

The classification and nomenclature of this genus are chaotic and desperately in need of a comprehensive study.

## Key to the Species of Coccotrypes (females only)

1. Strial setae entirely obsolete, interstrial bristles rather coarse; pronotum usually much more broadly convex both longitudinally and transversely, its anterior margin more broadly rounded and devoid of serrations2

- Rows of strial setae conspicuously present between rows of longer, fine, interstrial hair; pronotum more strongly, narrowly convex both longitudinally and transversely, its anterior margin more narrowly rounded and partly serrate

2(1). Pronotum smooth, shining, entirely devoid of asperities, punctures fine, deep, a few of them with one margin minutely granulate; sides of pronotum on anterior third converging rather abruptly; S Florida and Antilles Islands to Surinam, Hawaii to Indonesia, etc.; fruit or phloem of many hosts; $1.4-2.0 \mathrm{~mm}$ 1. advena Blandford

- Anterior half of pronotum finely asperate, devoid of punctures in asperate area; sides on anterior third of pronotum broadly rounded; larger species3

3(2). Pronotal asperities fine, more widely spaced, minute to almost obsolete on basal third; surface on posterior half of pronotum etched, subreticulate, shining; strial punctures rather coarse, striae almost as wide as interstriae; S Florida, Veracruz, etc.; Rhizophora mangle fruit; 2.2-2.5 mm ......... 2. rhizophorae (Hopkins)

- Pronotal asperities moderately coarse, close, extending to base, surface between asperities smooth, shining; strial punctures small, interstriae twice as wide as striae; Florida, Antilles Islands, Costa Rica to Panama, N South America, Java to India; fruit or phloem of many hosts; 1.7-2.3 mm

3. cyperi (Beeson)

4(1). Body slender, 2.5 times as long as wide; strial hair erect, almost as long as those of interstriae, both very fine; strial and interstrial punctures equally small, each with a fine granule on anterolateral margin; Cuba to Puerto Rico; Eutrepe globosa; 1.3 mm
4. robustus Eichhoff

- Body stouter, 2.1-2.2 times as long as wide; strial hair semirecumbent, shorter and finer than interstrial hair; strial punctures never with granules on margin

5(4). Pronotal asperities small, rather sparse, those at summit averaging less than twice as long (transversely) as thick, those at summit as high as those on anterior slope 6

- Pronotal asperities larger, closer, those at summit at least four times as long (transversely) as thick, higher on anterior slope than at summit
6(5). Smaller; interstrial bristles blunt, their apices often slightly flattened, each bristle only slightly longer than distance between interstrial rows; strial punctures small, very shallow, spaced within a row by two to three diameters of a puncture; Costa Rica to Brazil, etc.; 1.2 mm
- Larger; interstrial bristles pointed, each about twice as long as distance between interstrial rows; strial punctures shallowly impressed, separated by distances equal to diameter of a puncture; Florida, Honduras, Hawaii to Ceylon; $1.7-2.3 \mathrm{~mm}$ 6. distinctus (Motschulsky)
$7(5)$. Smaller; mature color dark brown to almost black; strial punctures very slightly smaller, shallow; interstrial granules on disc averaging smaller, more widely spaced; interstrial setae on declivity shorter, each only slightly longer than distance between rows; almost cosmopolitan; in palm fruits; $1.5-1.9 \mathrm{~mm} .$.
- Larger; mature color reddish brown; strial punctures slightly larger, very slightly deeper; interstrial granules averaging slightly larger, closer; interstrial setae on declivity longer, each almost twice as long as distance between rows; almost cosmopolitan; in palm fruits; $1.8-2.3 \mathrm{~mm}$ $\qquad$ 8. dactyliperda (Fabricius)

## 1. Coccotrypes advena Blandford

Coccotrypes advena Blandford, 1894, Trans. Ent. Soc. London 1894:100 (Holotype, female; Nagasaki, Japan; British Mus. Nat. Hist.)
Thammurgides persicac Hopkins, 1915, U.S. Dept. Agric. Rept. 99:45 (Holotype, female; Honolulu, Hawaii: U.S. Nat. Mus., 7614); Wood, 1973, Great Basin Nat. 33:174. Synonymy
Thamnurgides setosus Beeson, 1929, Insects of Samoa, Coleopt. 4:228 (Holotype, female; Fugasa, Tutuila, Samoa; British Mus. Nat. Hist.); Schedl, 1961. Rev. Ent. Moçambique 4:728. Synonymy

Thammurgides cubanus Eggers, 1934, Ent. Blăt. 30:79 (Holotype, female; Cuyajabas, Sierra Rosario, Cuba; U.S. Nat. Mus.. 60195); Wood, 1960, Insects of Micronesia 18(1):48. Synonymy
Poecilips nuciferus Schedl. 1938. Ent. Berichten 10:10 (Syntypes; Paramaribo, Surinam): Schedl, 1961, Rev. Ent. Noçambique 4:738. Synonymy
Thammargides vicarius Beeson, 1939, Indian For. Rec. 5:255 (Holotype, female; Samsing, Kalimpong, Bengal, India; Dehra Dumn); Schedl. 1961, Rev. Ent. Moçambique 4:72S. Synonymy
Poecilips niger Schedl, 1939, J. Fed. Malaya St. Mus. 18:345 (Syntypes; Malaya); Wood, 1960, Insects of Micronesia 18(1):48. Synonymy
Poecilips subnitidus Schedl, 1954, Philippine J. Sci. 83:147 (Holotype, female; Buitenzorg, Java: Schedl Coll.); Schedl, 1961, Rev. Ent. Mocambique 4:728. Synonymy
Diagnosis.- Among American species this one is distinguished by characters summarized in the above key. It is distinguished from the African sannio Schaufuss by the longer, more slender interstrial bristles, particularly on the declivity, and by the much smaller, almost obsolete granules on the anterior half of the pronotum.
Female.- Length $1.4-2.0 \mathrm{~mm}, 2.2$ times as long as wide; mature color very dark brown.

Frons broadly convex, rather weakly, convergently aciculate on lower third, sparse, fine, granulate punctures above, shining, subreticulate toward vertex; median line broadly, rather indistinctly elevated; vestiture of sparse, fine, long hair.

Pronotum 1.06 times as long as wide; widest just behind middle, sides moderately arcuate, converging rather strongly on anterior third, rather narrowly rounded in front; surface smooth and brightly shining to subreticulate (variable in series), finely, rather
sparsely punctured, most punctures on anterior half minutely granulate, asperities absent. Vestiture sparse, of fine, long hair.

Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; sides almost straight on basal half, slightly wider near base of declivity, narrowly rounded behind; striae 1 feebly, others not impressed, punctures moderately large, rather shallow; interstriae smooth, shining, about one and one-half times as wide as striae, punctures fine, uniseriate, minutely granulate on their anterior margins. Declivity rather steep, broadly convex; sculpture as on disc. Vestiture of rows of interstrial bristles only; each bristle slightly longer than distance between rows or between bristles within a row; each bristle slender, either slightly flatiened on its apical fourth or not.

Distribution.- Florida, Cuba to Surinam, and Hawaii to India.

Specimens have not been reported from North or Central America (except Florida); however, because it is well established in the Antilles, in Surinam, and in Hawaii, it may soon become established in Central America, Mexico, or on the Gulf of Mexico coast in the USA. One series taken at Coral Gables, Florida, may have been from a breeding population.

Hosts.- Numerous tropical trees having large seeds.

Biology.- This species breeds in bark and fruits of its hosts.

Notes.- The above treatment was based on the holotypes of advena, persicae, setosus, nuciferus, vicarius, and cubanus, on syntypes of niger, and on about 300 other specimens. Schedl (1963:267) listed subnitidus as a synonym of this species; I have not seen authentic specimens to confirm his observations. Schedl also treated sannio Schaufuss and bambesianus Eggers as synonyms of this species. Cotypes or syntypes of both were examined and I agree that they are synonyms of one another, but they are distinct from advena.

## 2. Coccotrypes rhizophorae (Hopkins)

 Fig. 175Spermatoplex rhizophorae Hopkins, 1915, U.S. Dept. Agric. Rept. 99:48 (Holotype, female; Miami, Florida; U.S. Nat. Mus. 7626)
Dendrurgus rhizophorac Eggers, 1923 (nee Hopkins, 1915), Zool. Meded. Roy. Mus. Nat. Hist. Leiden 7:149 (Syntypes; losel Saleyer and Moeara Antjol, Sumatra)
Poecilips rhizophorac: Schedl, 1952, Ent. Blätt. 47-48:160. Synonymy
Thamnurgides nephelii Eggers, 1936, Tijdschr. Ent. 79:84 (Holotype, female; Buitenzorg, Java; British Mus. Nat. Hist.); Kalshoven, 1958, Tijdschr. Ent. 101:176. Synonymy
Diagnosis.- This species is distinguished from other American representatives of the genus as indicated in the above key.

Female.- Length $2.2-2.5 \mathrm{~mm}$ (male 1.6 $\mathrm{mm}), 2.4$ times as long as wide; color reddish brown.

Frons essentially as in advena Blandford.
Pronotum 1.07 times as long as wide; outline about as in advena; surface shining,
subreticulate; slightly more than anterior half with fine, low, isolated, transverse asperities; posterior area with sparse, minute punctures, most of them minutely granulate or subasperate (see taxonomic notes). Vestiture of sparse, fine, long hair.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae weakly impressed, punctures moderately large, rather deep; interstriae smooth, shining, very slightly wider than striae, punctures uniseriate, fine, most of them finely granulate. Declivity rather gradual, broadly convex, more narrowly convex toward apex; sculpture as on declivity except striae 1 slightly more strongly impressed. Vestiture of rows of erect interstrial bristles; each bristle as long as distance between rows, or between bristles within a row; each bristle very slightly flattened on its apical third.

Fig. 175. Coccotrypes rhizophorae: 1-3, damage to seedling; 4, female. (Woodruff 1970:1.)

Distribution.-S Florida, Veracruz, Galapagos Islands, and Indonesia.

USA: Florida: Homestead, 19-VII-39, P. B. Lawson; La Belle, I6-VII-39, P. B. Lawson; Little River, 22 -VIIII8, Rhizophora mangle; Kev West, 20-VII-39, P. B. Lawson; Miami. 4-IX-70. MEXICO: Veracruz: Mandinga, I2-III-80, T. H. Atkinson. GALAPAGOS ISLANDS: Albermarle Ist., 4-14-III-06, F. X. Williams.

## Hosts.- Rhizophora mangle.

Biology.- The viviparous seeds of the host are attacked soon after they fall to the ground (Woodruff 1970).

Notes. - The above treatment was based on the holotype of rhizophorae (Hopkins), on 2 syntypes and 2 "homotypes" of rhizophorae (Eggers), and on 93 other specimens. One cotype and one other specimen of nephelii (Eggers) were also examined. The pronotal dise of rhizophorae (Eggers) is smooth, shining, rather coarsely, deeply punctured, and devoid of granules. Under ordinary circumstances it would be placed in a species different from that of Hopkins; however, the two specimens of nephehii are almost exactly intermediate between the two. All three agree completely in all other characters. In the absence of adequate Indonesian material, and in view of the similar habits, I reluctantly follow the synonymy proposed by Schedl and add nephelii as another synonym.

## 3. Coccotrypes cyperi (Beeson)

Thammurgides cyperi Beeson, 1929, Insects of Samoa, Coleoptera 4(4): 230 (Holotype, female, Apia, Samoan Islands, British Mus. Nat. Hist.)
Thamnurgides indicus Eggers, 1936, Ann. Mag. Nat. Hist. (10) 17:63I (Holotype, female; Sakalaspur, Mysore, India; British Mus. Nat. Hist.); Wood, 1978, Great Basin Nat. 38:397. Synonymy
Xyleborus conspeciens Schedl, 1936, Archiv. Inst. Biol. Veg. Río de Janeiro 3:110 (Holotype, female; Iocality not given, presumably Brazil; Schedl Coll.); Wood, 1973, Great Basin Nat. 33:179. Synonymy
Dryocoetes insularis Eggers, 1940 (nec. Eggers, 1940:I29), Arb. Morph. Tax. Ent. Berlin-Dahlem 7:127 (Syntypes; Guadeloupe and Martinique); Schedl, I962, Caribbean J. Sci. 2:63. Synonymy
Coccotrypes insularis Eggers, 1940 (nec. Eggers, 1940:127), Arb. Morph. Tax. Ent. Berlin-Dahlem 7:129 (Lectotype, female; Trois-Rivières, Guadeloupe; U.S. Nat. Mus., 606I2, designated by Anderson and Anderson, 1971, Smithsonian Contrib. Zool. 94:15); Schedl, I962, Caribbean J. Sci. 2:63. Synonymy
Dryococtes subimpressus Eggers, 1940, Arb. Morph. Tax. Ent. Berlin-Dahlem 7:I27 (Holotype, female; Trois Rivières Guadeloupe; deposited in Eggers

Collection, apparently on loan to Schedl); Wood, 1977, Great Basin Nat. 37:384. Synonymy
Poecilips caraibicus Schedl, 1952, Dusenia 3:345 (Replacement name for Dryocoetes insularis Eggers)
Poecilips eggersi Schedl. I952, Dusenia 3:347 (Replacement name for Coccotrypes insularis Eggers)
Diagnosis.- This species is distinguished from other American representatives of the genus by characters summarized in the above key.

Female.- Length $1.7-2.3 \mathrm{~mm}$ (males $1.1-1.2 \mathrm{~mm}$ ), 2.3 times as long as wide; rather dark reddish brown.

Frons broadly convex, convergently, rather finely aciculate from epistoma to upper level of eyes, with fine, rather deep punctures interspersed, rugose-reticulate above; vestiture of sparse, fine hair.

Pronotum 1.08 times as long as wide; outline as in advena Blandford; surface smooth, shining, rather closely, somewhat coarsely asperate to base, those on posterior half decreasing in size, a few punctures interspersed near base of disc. Vestiture of sparse, fine hair; usually abraded.

Elytra 1.4 times as long as wide, 1.4 times as long as pronotum; outline about as in rhizophorae; striae not impressed, punctures small, rather shallow; interstriae smooth and shining, twice as wide as striae, punctures uniseriate, fine, minutely granulate. Declivity rather steep, convex; sculpture as on disc. Vestiture of rows of erect, blunt, interstrial bristles; each bristle about one and one-half times as long as distance between rows or between bristles within a row; each very slightly flattened at extreme tip.

Male.-Similar to female except much smaller, callow, more strongly convex, usually somewhat deformed, eyes reduced or absent.

Distribution.-Florida, Costa Rica to Panama, Antilles Islands to Surinam, Java to India.
USA: Florida: Coral Gables, 6-III-56, in imported bird seed, C. F. Downing. Louisiana: 10-VIII-34, Persea americana seed from Honduras. COSTA RICA: San José, San José, 16-1I-38, Prionia capaifera seeds, F. Nevermann; Finca La Lola, Limón, 22-VI-63, Thcobroma cacao. J. L. Saunders; Pandora, Limón, 23-VIII-63, 50 m , No. I89, Cynometra hemitobophylla, S. L. Wood; Dominical, 9-XII-63, 3 m , No. 294, legume tree, S. L. Wood. PANAMA: Barro Colorado Island, Canal Zone, 27-XII-63, No. 346, Entada giga, S. L. Wood; Limón Bay, Canal Zone, 30-XII-63, 3 m , No. 357, fallen fruit, S. L. Wood. OTHER COUNTRIES: Puerto Rico, Surinam,

Martinique, Guadeloupe, Trinidad, Brazil, Hawaiian Islands, Fiji, Tahiti, Indonesia, India, French Indo-China.

Hosts.- Eugenia sp., Mangifera indica, Mammea americana, Orbignya oleifera, Cynometra hemitobophylla, Persea americana, Phytelephas macrocarpa, Pronia copaifer, Theobroma cacao, etc.

Biology.- This species breeds in large seeds of fallen fruit; it is also capable of reproducing in bark. Browne (1961) records it from nine host species in Malaya. New attacks are made by females. Field observations indicate the habits in fruit are as described for the genus. Several males, so recently emerged they were entirely white and almost totally unsclerotized, were observed to mate repeatedly with sibling females in the brood galleries.

Notes. - The above treatment was based on the holotypes of cyperi, indicus and conspeciens, to the lectotype of Coccotrypes insularis, and to two syntypes of Dryococtes insularis. This species was evidently introduced to America from the Indo-Malayan area prior to 1915. The earliest known American specimens were taken at San José, Costa Rica, 6-V-15.

## 4. Coccotrypes robustus Eichhoff

Coccotrypes robustus Eichhoff, 1878, Mém. Soc. Roy. Sci. Liége (2)8:58, 313 (Syntypes?; Cuba; presumably lost with Hamburg Mus.)
Coccotrypes cylindricus Schedl, 1949, Tijdschr. Ent. 91:116 (Holotype, female; Crucos, Cuba; Schedl Coll.); Wood, 1975, Great Basin Nat. 35:393. Synonymy
Diagnosis.- This species is distinguished from other species of this genus known to me by the slender body form, by the very minute strial granules, and by the fine strial hair that is almost as long as the equally fine interstrial hair.

Female.- Length $1.3 \mathrm{~mm}, 2.5$ times as long as wide; color dark brown.

Frons broadly convex, convergently aciculate from epistoma to upper level of eyes, a few fine, obscure punctures in upper areas; vestiture of sparse, fine hair of moderate length. Antennal club 1.5 times as long as wide.

Pronotum 1.1 times as long as wide; widest just behind middle, sides moderately arcuate, converging on anterior half to rather narrowly rounded anterior margin; asperate to base,
asperities rather fine, close, those on posterior third associated with fine, shallow, obscure punctures; surface between asperities smooth, shining; median line obscurely developed. Vestiture of very fine, rather abundant, moderately long hair.

Elytra 1.5 times as long as wide, 1.3 times as long as pronotum; sides almost straight and parallel on basal two-thirds, broadly rounded behind; striae not impressed, punctures small, shallow, those on I and 2 with anterolateral margins slightly elevated forming obscure, fine, granules; interstriae four times as wide as striae, smooth, shining, punctures fine, uniseriate, close, each with a small granule on anterolateral margin, granules equal in diameter to strial punctures. Declivity steep, broadly convex; sculpture essentially as on disc. Vestiture of rows of fine, erect, strial and interstrial hair of equal length and appearance; each hair slightly longer than width of an interstriae on dise, slightly longer on declivity.

Distribution.- Cuba and Puerto Rico.
Not recorded from Mexico or Central America, although appropriate hosts apparently occur there.

Hosts.- Eutrepe globosa.
Biology.- This species has been reared from the fruits of its host.

Notes. - The above treatment was based on 2 females of robustus that were compared by Hopkins to a syntype, on the holotype of cylindricus, and on 18 other specimens. This is the only American member of this genus not known from some part of the Eastern Hemisphere. It will be most surprising if this actually is a native American species.

## 5. Coccotrypes aciculatus Schedl

Coccotrypes aciculatus Schedl, 1952, Dusenia 3:360 (Holotype, female; Hamburgfarm on Río Reventazon, Limon, Costa Rica; Schedl Coll.)
Diagnosis.- This species is distinguished from distinctus (Motschulsky) by the small size, by the more widely spaced strial punctures, and by the stouter, blunt, interstrial bristles.

Female.- Length $1.2 \mathrm{~mm}, 2.0$ times as long as wide; color reddish brown.

Frons essentially as in robustus Eichhoff.
Pronotum 1.0 times as long as wide; widest just behind middle, sides moderately arcuate, converging on anterior half to rather broadly
rounded, subserrate anterior margin; strongly convex, with indefinite summit slightly behind middle; asperities on anterior slope small, sparse, intermixed with sparse, fine, shallow punctures; small, sparse, subasperate granules in posterior area to base; surface smooth, shining; an obscure, raised, basal line indicated. Vestiture of rather sparse, blunt hair of moderate length.

Elytra 1.2 times as long as wide, 1.3 times as long as pronotum; sides almost straight and parallel on slightly more than basal half, rather broadly rounded behind; striae not impressed, punctures moderately small, distinct but very shallow, spaced within a row by about two to three diameters of a puncture; interstriae about twice as wide as striae, smooth, shining, punctures replaced by small, uniseriate, widely spaced granules. Declivity moderately steep, rather broadly convex; sculpture essentially as on disc. Vestiture of short, fine, strial hair and rows of erect, blunt, interstrial bristles, each bristle as long as distance between rows or between bristles within a row.

Distribution.- Costa Rica to Panama, Brazil, New Guinea.
PANAMA: Barro Colorado Island, Canal Zone, NI-30, F. C. Lutz. OTHER COUNTRIES: Brazil; Schedl (I950:148, 1955:280) adds Hamburgfarm on Rio Reventazón, Limón, Costa Rica (type locality), Brazil, and New Guinea.

Notes.- The above treatment was based on a female from Barro Colorado Island identified by Schedl and on 55 other specimens. If Schedl's identifications of the specimens from Panama and New Guinea are accurate, it suggests that this species was introduced to America from another region, possibly from New Guinea or a neighboring area.

## 6. Coccotrypes distinctus (Motschulsky)

Anodius distinctus Motschulsky, I866, Moskov. Obshch. Isp. Prirody, Otd. Biol. Biul. (Bull. Soc. Imp. Nat. Moscou) 3I(1):401 (Holotype, female; published as "Des Montagues de Nura-Ellia," the specimen is labeled "Ceylon"; Zool. Inst. Acad. Sci. USSR. Moscow)
Coccotrypes floridensis Schedl, 1949, Tijdschr. Ent. 91:117 (Syntypes; Winter Park, Florida); Wood, 1969, Great Basin Nat. 29:117. Synonymy
Dlagnosis.- This species is distinguished from aciculatus Schedl by the larger size, by the more deeply impressed, more closely
spaced strial punctures, and by the longer, more slender, pointed interstrial setae.

Female.- Length $1.7-2.3 \mathrm{~mm}$ (male 1.3 mm ), 2.2 times as long as wide; color reddish brown.

Frons essentially as in robustus Eichhoff, but usually with median line more prominently raised.

Pronotum as in aciculatus Schedl except minute asperities very slightly more numerous, none of asperities more than twice as long (transversely) as thick (longitudinally); setae finer, slightly longer.

Elytra 1.2 times as long as wide, 1.3 times as long as pronotum; outline about as in aciculatus; striae not impressed, punctures rather small, distinctly impressed, separated within a row by diameter of a puncture; interstriae about three times as wide as striae, smooth, shining, punctures replaced by small, widely spaced, uniseriate granules. Declivity rather steep, convex; sculpture as on disc. Vestiture of rows of semirecumbent strial hair, each half as long as distance between rows; and rows of fine, pointed, erect interstrial bristles, each bristle slightly longer than distance between rows or between bristles within a row.

Male.-Similar to female except much smaller ( 1.3 mm ), slightly deformed, characters usually imperfectly developed; no two males exactly alike.

Distribution.- Florida, Honduras, Hawaii to Ceylon.

USA: Florida: Apopka, 3-IN-58, Neanthebella palm seeds. Van Pelt; Coconut Grove, VII-60. Coceothrinus seeds: Gainesville, VII-60, Phoenix sylvestris; Hilliard, 6-vill-39, R. H. Beamer: La Belle, 16-VII-39, R. H. Beamer; Miami Beach, 6-VII-56. Phocnix canaricnsis, L. J. Daigle; Melbourne, 9-VII-51, at light, S. L. Wood: Winter Park, $24-\mathrm{X}-46$, palm seed. H. Y. Gouldman. HONduras: La Ceiba, 29-V, 26-VIII-49, at light, E. C. Becker. OTHER COUNTRIES: Puerto Rico, British Guiana, Hawaii, Micronesia, and Ceylon.

Hosts.-Coccothrinus sp., Phoenix spp., etc.

Biology.- This species breeds in a wide variety of palm seeds.

Notes.- The female holotype of distinctus was examined, but specimens were not at hand for direct comparison to it. The above treatment was based on syntypes of floridensis and on 73 other specimens. This is the species treated by me prior to 1970 as carpophagus (Hornung); the erroneous
identification was based on the specimens from Guam incorrectly reported by Schedl (1942:148) as carpophagus.
7. Coccotrypes carpophagus (Hornung)

Bostrichus carpophagus Hornung, 1842, Stettiner Ent. Zeit. 3:116 (Syntypes; intercepted in Germany from Betelnüssen of Ostindien origin)
Coccotrypes pygmacus Eichhoff, 1878, Mém. Soc. Roy. Sci. Liége (2)8:58, 310 (Syntypes; Madagascar; presumably lost in Hamburg Mus.); Schedl, 1959, Trans. Roy. Ent. Soc. London 111:486. Synonymy
Coccotrypes integer Eichhoff, 1878, Mém. Soc. Roy. Sci. Liége (2)8:58. 311 (Syntype, female; Siam; one in U.S. Nat. Mus., others lost with Hamburg Mus.); Eggers, 1929, Wiener Ent. Zeit. 46:52. Synonymy
Cryphaloidcs donisthorpei Formanek, 1908, Ent. Blätt. 4:91 (Syntypes, females; Kew Gardens, London, England; British Mus. Nat. Hist.); Schedl, 1962, Mitt. Münchner Ent. Ges. 52:95. Synonymy
Coccotrypes thrinacis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:46 (Holotype, female; Isle of Pines, Cuba; U.S. Nat. Mus., 7617); Schedl, 1964, Reichenbachia 2:216. Synonymy
Coccotrypes bakeri Hopkins, 1915, U.S. Dept. Agric. Rept. 99:46 (Holotype, female; Havana, Cuba; U.S. Nat. Mus., 7619); Schedl, 1964, Reichenbachia 2:216. Synonymy
Coccotrypes anonae Hopkins, 1915, U.S. Dept. Agric. Rept. 99:46 (Holotype, female; Cuba; U.S. Nat. Mus., 7624); Schedl, 1950, Dusenia 1:145. Synonymy
Coccotrypes hubbardi Hopkins, 1915, U.S. Dept. Agric. Rept. 99:46 (Holotype, female; Montserrat, West Indies; U.S. Nat. Mus., 7620 ); Schedl, 1950, Dusenia 1:146. Synonymy
Coccotrypes liberiensis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:47 (Holotype, female; Mount Coffee, Liberia; U.S. Nat. Mus., 7615); Wood, 1975. Great Basin Nat. 35:392. Synonymy
Coccotrypes rollinae Hopkins, 1915, U.S. Dept. Agric. Rept. 99:47 (Holotype, female; Pará, Brazil; U.S. Nat. Mus. 7616); Schedl, 1950, Dusenia 1:145. Synonymy
Coccotrypes nanus Eggers, 1920, Ent. Blätt. 16:33 (Lectotype, female; Kamerun; U.S. Nat. Mus., 60717, designated by Anderson and Anderson, 1971, Smithsonian Contrib. Zool. 94:21); Schedl, 1949, Tijdschr. Ent. 91:114. Synonymy
Coccotrypes punctulatus Eggers, 1951, Ent. Blätt. 45-46:151 (Holotype, female; Insel St. Thomas, Virgin Islands; deposited in Eggers Coll. but now apparently on loan to Schedl); Wood, 1975, Great Basin Nat. 35:392. Synonymy
$D_{\text {Iagnosis. }}$ - This species is distinguished from dactyliperda (Fabricius) by the smaller size, by the darker color, by the smaller average size of the strial punctures and of the interstrial granules on the elytral dise, and by the shorter interstrial bristles.

Female.- Length $1.5-1.9 \mathrm{~mm}$ (males $1.2-1.3 \mathrm{~mm}$ ), 2.2 times as long as wide; color very dark brown to almost black.

Frons broadly concave, weakly, transversely impressed on lower half; surface shining, rather coarsely, convergently aciculate from vertex to epistoma, a few fine, obscure punctures above; vestiture of sparse, fine, long hair.

Pronotum 1.05 times as long as wide; outline as in distinctus; anterior margin rather coarsely serrate; asperate to base, asperities moderately coarse, close, abundant, those behind summit longitudinal and about four to six times as long as thick; punctures not evident. Vestiture of rather sparse hair of moderate length.

Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; outline as in distinctus; striae not impressed, punctures small, distinct, very shallow; interstriae smooth, shining, three to four times as wide as striae, punctures replaced by small, uniseriate granules. Declivity rather steep, broadly convex; sculpture as on disc. Vestiture of rows of short, recumbent strial hair, and rows of erect interstrial bristles, each bristle slender, blunt, very slightly longer than distance between rows or between bristles within a row.

Male.-Similar to female except smaller ( $1.2-1.3 \mathrm{~mm}$ ), slightly deformed, with characters poorly formed; usually no two specimens exactly alike.

Distribution.- Cosmopolitan through commerce, but breeding only in tropical and subtropical areas where hosts grow.

USA: District of Columbia: Washington. Florida: Coconut Grove, VII-60, Coccothrimax, Litistonia chinensis and Sabal palmetto seeds. New Jersey: Short Hills, 19-IV-26, intercepted in seeds from Brazil, F. M. Schott. MEXICO: Veracruz. HONDURAS: La Lima, 1II-67, Annona muricata seeds. GUATEMALA: Guatemala. OTHER COUNTRIES: Bermuda, Cuba, Puerto Rico, Jamaica, Trinidad, British Guiana, Surinam, Grenada, Colombia, Brazil, Peru, Hawaii, France, England, Cameroons, Ceylon, India, Java, Guam, Australia.

Hosts.- Annona muricata, Coccothrinax sp., Livistonia chinensis, Sabal causiarum, Thrimax sp., etc.

Biology.- This species breeds in large seeds. Evidently the habits are essentially as described for the genus.

Notes. - The above treatment was based on the holotypes of thrinacis, bakeri, anonae, hubbardi, rollinae, liberiensis and punctulatus, on syntypes of carpophagus and Cryphaloides donisthorpei, and on more than

2,000 other specimens. Schedl and Eggers report the synonymy of pygmacus, integer, and nanus with carpophagus; I have not verified their synonymy. Three "types" of carpophagus are in the Berlin Museum; all were examined. In all probability they are the only remaining syntypes of this species, but a lectotype was not selected.

Coccotrypes pubescens Schedl (1949:119) is known from one female taken at Sierra Bonilla, Cuba. Probably it is of carpophagus, but the interstrial setae are very slightly longer than normal and the strial setae are almost as long as those of the interstriae. I hesitate to place it in synonymy until more material from this area can be studied.

## 8. Coccotrypes dactyliperda (Fabricius)

Bostrichus dactyliperda Fabricius. 1801. Systema Eleutheratorum 2:387 (Syntypes: in date pits intercepted in Europe; Copenhagen Mus.. Kiel Coll., one in Berlin Mus.)
Bostrichus palmicola Hornung, 1842, Stettiner Ent. Zeit 3:116 (Syntypes; intercepted in Germany); Balachowsky, 1949, Faune de France 50:182. Synonymy
Coccotrypes laboulbenei Decaux, 1890, Études sur les insects recueillis a lexposition universal, Paris, 16 p. (Not seen); Bedel, 1891, L'Abbeille 27:155. Synonymy
Coccotrypes cggersi Hagedorn. 190.4, Allg. Zeitschr. Ent. 9:449 (Syntypes: Ecuador; only known syntype in U.S. Nat. Mus., others evidently destroyed in Hamburg Mus.): SchedI, 1949, Tijdschr. Ent. 91:113. Synonymy
Coccotrypes bassiavorus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:47 (Holotype, female; Washington. D.C.; U.S. Nat. Mus., 7618); Wood, 1975. Great Basin Nat. 35:392. Synonymy
Coccotrypes morcirai Eggers. 1925, Arch. 1nst. Biol. I:86 (Lectotype, female; Minas Garaes, Guaxupè. Brazil; U.S. Nat. Mus., 60613, designated by Anderson and Anderson, 1971, Smithsonian Contrib. Zool. 94:2I); Schedl, 1949, Tijdschr. Ent. 91:113. Synonymy
Coccotrypes tanganus Eggers, 1935, Rev. Zool. Bot. Afr. 27:307 (Holotype, female; Tanga, Tanga, Tanganyika; British Mus. Nat. Hist.); Schedl, 1949. Tijdschr. Ent. 91:1I3. Synonymy

Diagnosis.- This species is distinguished from carpophagus (Hornung) by the larger size, by the lighter color, by the deeper and slightly larger strial punctures, and by the longer interstrial bristles.

Female.- Length $1.8-2.3 \mathrm{~mm}, 2.3$ times as long as wide; color reddish brown.

Frons as in carpophagus. Pronotum as in carpophagus except anterior margin less coarsely, less regularly serrate: asperities more numerous, each smaller in basal area but averaging as high or slightly higher.

Elytra 1.3 times as long as wide; as in carpophagus except strial punctures averaging very slightly larger, distinctly deeper, interstrial granules closer, averaging slightly larger; interstrial bristles more slender, pointed, each about one and one-half to two times as long as distance between rows, more closely spaced within a row.

Distribetion.- Cosmopolitan through commerce, but breeding only in tropical and subtropical areas where hosts grow.

US A: Arizona: Mesa. 6-VIIl-60, at light, S. L. Wood: Tucson, 10-X-68. California: Los Angeles. Texas: Brownsville. MEXICO: Baja California: Rancho de la Ventana. Bahía de la Ventana, 19-X11-58, in flight, H. B. Leech. "Mexico." PANAMA: "Panama." OTHER COUNTRIES: Cuba, Colombia, Brazil. Ecuador, Venezuela. Hawaiian Islands, Australia. New Zealand, Indonesia, New Guinea, Malaya, India, Japan, Arabia, Sudan, Israel, France, Italy, Portugal.

Hosts.- Date pits, etc.
Biology.- This species breeds mostly in the seeds of various palms, but many other large seeds are also attacked. It commonly infests buttons of vegetable ivory even when they are polished and painted. Large quantities of these buttons have been destroyed in warehouses in the Indo-Malayan region.

The habits are about as described for the genus.

Notes.- The above treatment was based on syntypes of palmicola, eggersi, and tanganus, on the holotype of bassiavorus, on the lectotype of moreirai, and on about 200 other specimens.

## Tribe CRYPTURGINi

Crypturgi LeConte, 1876, Proc. Amer. Philos. Soc. 15:387 (Type-genus: Crypturgus Erichson, 1836)

Anatomical features. - The frons is usually not sexually dimorphic, its sculpture is simple, the posterodorsal area of the head is moderately produced caudad, the eye is sinuate to emarginate, the antennal funicle is $2-3$-segmented, the club is moderately flattened, with the sutures on the anterior and posterior faces about equal, the pronotum is unarmed (American species) and weakly declivous in front, the lateral margins are rounded, the procoxae are contiguous, and the declivity is simple and unarmed.

Biological features.- All species are monogamous and phloeophagous. Crypturgus normally uses the tunnel of another insect to gain entry into the host. The galleries and habits have not been studied in detail.

Taxonomy. - The three native North American species in this tribe were obviously derived from the Asian fauna rather recently. All allied forms occur in Eurasia and northern Africa. More distant affinities appear to be with the Dryocoetini. The American forms are easily recognized.

## Genus CRypturgus Erichson

Crypturgus Erichson, 1836, Archiv Naturgesch. 2:60 (Type-species: Bostrichus pusillus Gyllemhal, subsequent designation by Thomson, 1859, Skandinaviens Coleoptera synoptiskt bearbetade $1: 147$ )
$\mathrm{D}_{\text {lagnosis. }}$ - This genus is distinguished from Dolurgus Eichhoff by the smaller size, by the 2 -segmented antennal funicle, and by the solid antennal club with a partial septum
where suture 1 should be and an indistinct suture near the apex.

Description.- Length $1.0-1.2 \mathrm{~mm}, 2.8$ times as long as wide; color dark brown to black. Sexes similar. Frons convex, sculpture simple. Eye oval, deeply emarginate; finely granulate. Antennal funicle 2 -segmented; club small, solid, an indistinct suture at apex. Pronotum longer than wide, evenly arched, sparsely punctured throughout, summit indefinite. Scutellum small. Elytra striate; declivity convex, rather steep; females in two species bearing a spongy area near apex on lower half of declivity. Tibiae rather broad, widest on distal third; outer margin armed by a series of about six coarse teeth.

Distribution.- Canada and the United States, Europe, northern Asia, and north Africa; about 12 species are known, 3 occur in North America.

Biology.- The bole of coniferous hosts is selected for attack. The beetles locate the entrance hole of another insect, usually a bark beetle, to gain access to the phloem tissues. Here they commence the excavation of their own tunnels, usually at the cambium perpendicular to the gallery of the host insect. Their irregular tunnels extend $1-3 \mathrm{~cm}$; eggs are deposited along the margins, apparently in niches. Larval mines are difficult to follow, but apparently they wander through the phloem up to 3 cm from their origins. There appears to be one generation pe year. They overwinter as adults in the brood galleries.

## Key to the Species of Crypturgus

1. Pronotal disc subreticulate, lines radiating from punctures only; elytra smooth, shining, discal pubescence almost obsolete, very short on sides and declivity; interstriae wider than striae; female without spongy area on declivity; Ontario and Newfoundland to New Jersey, etc.; Abies, Picea; 1.1-1.2 mm
2. pusillus (Gyllenhal)

- Pronotum uniformly, strongly reticulate; interstriae slightly narrower than striae, their surface often irregular, subshining; interstrial and strial hair conspicuous on disc and declivity; female with a spongy area near apex of declivity

2(1). Strial punctures rather large, rather sharply impressed; interstriae mostly smooth, shining; interstrial setae short, in rows, each about half as long as distance between rows, strial setae semirecumbent, about as long as interstrial setae; E Texas to New Jersey and Florida; Pinus; 1.0-1.2 mm
2. alutaceus Schwarz

- Strial punctures rather small, shallow, not clearly outlined; interstriae with transverse lines, rather irregular, subshining; interstrial setae rather long, closely set, in rows, each as long as distance between rows on disc, strial setae semirecumbent, almost as long as those of interstriae; Alaska and Nova Scotia to Arizona and Pennsylvania; Abies, Picea; $1.0-1.2 \mathrm{~mm}$

3. borealis Swaine

## 1. Crypturgus pusillus (Gyllenhal)

Bostrichus pusilhus Gyllenhal, 1813, Insecta Svecica descripta, Coleopt. 1(3):371 Syntypes?; presumably Sweden; presumably at Univ. Uppsala)
Bostrichus aphodiodes Villa, 188:3, Col. Eur. Suppl., p. 36 (Syntypes; Europe: not located): Hagedorn, 1910: Coleopt. Cat. 4:36. Stnonymy
Cryphurgus atomus LeConte, 1868, Trans. Amer. Ent. Soc. 2:152 (Holotype, sex?; New York; Mus. Comp. Zool., 983); W'ood, 1973, Great Basin Nat. 33:175. Synonymy
Crypturgus parallelocollis Eichhoff, 1878, Mem. Soc. Roy. Sci. Liége (2)8:73 (Syntypes?; Europe; presumably lost with Hamburg Mus); Schedl, 1946, Zbl. Ges. Ent. 1:7. Synonymy
Crypturgus gauncrsdorferi Reitter, 1885, Deutsch. Ent. Zeitschr. 29:389 (Syntypes?; Euboea Isl., Greece; not located); Eggers, 1922, Ent. Blätt. 18:118. Synonymy
Crypturgus cribrellus Reitter, 1894, Naturf. Vereines Berlin 33:64 (Syntypes?; Ragusa, Dalmatia; not located); Schedl, 1946, Zbl. Ges. Ent. 1:7. Symonymy
Crypturgus maulci Roubal, 1910, Rev. Russ. d'Ent. 10:203. (Syntypes?; Litauen; not located); Schedl, 1946, Zbl. Ges. Ent. 1:7. Synonymy
Crypturgus danicus Eggers, 1932, Ent. Medd. 18:80 (Holotype, male; Insel Seeland, Denmark; U.S. Nat. Mus.); Schedl. 1946, Zbl. Ges. Ent. 1:7. Synonymy
Crypturgus cylindricollis Eggers, 1940, Centrbl. Ges. Forstw. 66:37 (Holotype, female; Lastua, Dalmatia; not located); Schedl, 1946, Zbl. Ges. Ent. 1:7. Synonyiny
Diagnosis.- This species is distinguished from borealis Swaine and alutaceus Schwarz by the subreticulate, shining pronotal disc, by the subglabrous, shining elytra, and by the
absence of a spongy area on the female declivity.

Male.- Length $1.1-1.2 \mathrm{~mm}, 2.8$ times as long as wide; color dark brown.

Frons convex; surface reticulate, punctures fine, obscure; vestiture inconspicuous.

Pronotum 1.2 times as long as wide; widest near middle, sides moderately arcuate, converging equally anteriorly and posteriorly, anterior and posterior margins equally, rather narrowly rounded; surface reticulate at margins, subreticulate and shining toward disc, punctures moderately coarse, deep, not close. Vestiture hairlike, restricted to peripheral areas.

Elytra 1.8 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on more than basal two-thirds, rather narrowly rounded behind; striae 1 feebly, others not impressed, punctures rather small, deep; interstriae wider than striae, smooth, shining, interstrial punctures minute to obsolete. Declivity convex, moderately steep; strial punctures smaller than on declivity. Vestiture almost obsolete on disc, consisting of rows of minute strial and slightly longer interstrial hair; longest setae on declivity equal to less than half distance between rows.

Female.- Similar to male.
Distribution.- Ontario and Newfoundland to New Jersey; north Africa, Europe, northern Asia.

CANADA: New Brunswick: Fredricton, St. Stephen. Newfoundland: Middlebrook Prov. Pk. Nova Scotia: Cape North, Kejimkujik Lake, Weymouth. Ontario: Rockcliffe, Wooley. Quebec: Chelsea. USA: Connecticut: Cornwall. Maine: Bar Harbor, Camp Caribon, Orono, Paris, Portland. Massachusetts: Cambridge, Charlemont, Framingham, Westboro. New Hampshire: Durham, Mt. Washington, Waterville. New Jersey: New Egypt. New York: Cicero Swamp, Cranberry Lake, Elka Park, Kingsbridge, Syracuse, Wanakena. Pennsylvania: Pocono Lake. Rhode Island: Providence.

Host.-Abies sp., Picea glauca, P. rubens.
Brology.-As described for the genus.
Notes.- The above treatment was based on the holotype of atomus, on 182 other American specimens, and on several hundred specimens from Europe and Asia. The distribution suggests an introduction to this continent during the early settlement of North America.

## 2. Crypturgus alutaceus Schwarz

Crypturgus alutaceus Schwarz, 1894, Proc. Ent. Soc. Washington 3:17 (Lectotype, male; Tampa, Florida; U.S. Nat. Mus., 4561, present designation)
Diagnosts. - This species is distinguished from pusillus (Gyllenhal) by the more strongly reticulate pronotum, by the larger strial punctures, by the longer, more abundant elytral vestiture, and by the small spongy area on the female elytral declivity.

Male.-Length $1.0-1.2 \mathrm{~mm}, 2.7$ times as long as wide; color dark brown to black.

Frons and pronotum essentially as in $p u$ sillus, except pronotal surface uniformly reticulate, subshining. Elytra as in pusillus, except strial punctures slightly larger, interstriae with occasional transverse lines; vestiture consisting of rows of erect interstrial and semirecumbent strial hair, interstrial setae on disc equal in length to half distance between rows, strial setae shorter.

Female.- Similar to male except lower half of elytral declivity on interstriae 1 and 2 appearing spongy (somewhat variable).

Distribution-E Texas to New Jersey and Florida.

USA: Florida: Big Pine Key, Royal Palm St. Pk., Sebring, Suwannee Springs, Walton Co. Georgia: Athens, Camelia, Clarke Co., Everett, Hays, Monroe Co., Thomasville. Louisiana: La Salle Parish. Maryland: Beltsville, Bladensburg, Dowell. Mississippi: Baxterville, Lucedale. New Jersey: Lahaway. North Carolina: Boardman, Durham, Tryon. Texas: Kirbyville, Polk Co.

Virginia: King William Co., Mt. Vernon. West Virginia: Davis in Tucker Co., Dellslow, Grant Co., Pocahontas Co., Wood Co.

Hosts.- Picea mariana, Pinus echinata, P. plustrus, P. taeda.

Biology.-As described for the genus.
Notes. - The above treatment was based on the syntypic type series of 8 specimens and on 95 other specimens. From the syntypes I here designate a male from Tampa, Florida, as lectotype for Crypturgus alutaceus Schwarz; this specimen at the U.S. National Museum has been considered to be the type for many years, but it was never so designated.

## 3. Crypturgus borealis Swaine <br> Fig. 176

Crypturgus borealis Swaine, 1917, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(I):7 (Lectotype, female: Winnipeg, Manitoba; Canadian Nat. Coll., 9287, designated by Bright, 1967, Canadian Ent. 99:673)
Crypturgus corrugatus Swaine, 1917, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. $14(\mathrm{I}): 8$ (Lectotype, female; North Mountain, Pennsylvania; Canadian Nat. Coll., 9286, designated by Bright. 1967, Canadian Ent. 99:673); Wood, I957, Canadian Ent. 89:396. Synonymy
Diagnosis.- This species is distinguished from alutaceus Schwarz by the smaller, shallow strial punctures, by the irregular interstriae, and by the much longer vestiture.

Male.- Length $1.0-1.2 \mathrm{~mm}, 2.8$ times as long as wide; color dark brown to almost black.

Frons and pronotum as in alutaceus, pronotal punctures smaller, obscure. Elytra as in alutaceus except strial punctures smaller, less clearly impressed, interstriae with a few transverse lines and impressed points to almost densely subrugulose in some specimens; strial punctures reduced in size on declivity; vestiture longer, interstrial setae as long as distance between rows.

Female.- Similar to male except with a spongy area on declivital interstriae 1 and 2 (variable) as in alutaceus.

Distribution.- Alaska and Nova Scotia to Arizona and Pennsylvania.

ALASKA: Fairbanks, Porcupine River. CANADA: Alberta: Banff, Edmonton, Lesser Slave Lake, Slave Lake. British Columbia: Likely, Nicomin Ridge, Pine Pass, Trinity Valley. Manitoba: Winnipeg. New Brunswick:

Fredricton. Northwest Territories: Aklavik. Nova Scotia: St. Ann. Ontario: Algonquin N.P.. Orillia. Ottawa. Quebec: Aylmer, Mt. Lyall, Gaspé, Trinity Bay. Saskatchewan: Prince Albert N.P. USA: Arizona: Ft. Apache Indian Res., Grand Canyon N.P., Whiteriver. Colorado: Gould, Neweastle, Poudre Canyon, Rabbit Ears Pass, Ridgeway. Idaho: Moscow Mts., Franklin Co. Maine: Camp Caribou. Michigan: Grand Island, Seney. Missouri: Eminence. New Mexico: Sandia Mts. New York: Cranberry Lake, Elka Park, Heart Lake in Essex Co. Montana: Blackfeet N.F., Drummond, Pray. Oregon: Gold Lake in Willamette N.F. Pennsylvania: North Mountain. South Dakota: Black Hills. Utah: Logan Canyon, Logan Dry Canyon, La Sal Mts., Soapstone Creek in Wasatch N.F.

Hosts.-Abies balsamea, A. concolor, A. grandis, A. lasiocarpa, Picea engelmannii, $P$. glauca, P. rubens, Pimus contorta, P. echinata, P. ponderosa.

Biology.- As described for the genus.
Notes.- The above treatment was based on the type series of borealis and corrugatus, on my homotypes of both, and on 374 other specimens.

Fig. 176. Dorsal aspect of adult: a, Cryphalus ruficollis; b, Crypturgus borealis; c, Dolurgus pumilus: d, Trypodendron betulae. (After Bright 1976:210.)

## Genus DOLURGUS Eichhoff

Dolurgus Eichhoff, 1868, Berliner Ent. Zeitschr. 12:147
(Type-species: Hylastes pumilus Mannerheim, monobasic)
Diagnosis.- This genus is distinguished from Crypturgus Erichson by the 3 -segmented antennal club, and by the presence of three feebly recurved sutures on the anterior face of the antennal club. It is distinguished from Aphanarthrum Wollaston by the aseptate suture 1 on the antennal club, and by the coarsely striate elytra.

Description.-Length $1.6-1.9 \mathrm{~mm}, \quad 2.7$ times as long as wide. Sexual differences not apparent. Frons convex, simple. Eye oval, deeply emarginate; finely granulate. Scape rather short; funicle 3 -segmented; club small, three aseptate, feebly recurved sutures on distal half of anterior face. Pronotum longer than wide, lateral margins rounded; surface punctured, unarmed. Scutellum small. Elytra striate, sculpture simple. Tibiae rather broad, widest on distal fourth; armed by several coarse teeth.

Distribution.- Northwestern North America. Only one species is known.

## Dolurgus pumilus (Mannerheim)

Fig. 176
Hylastes pumilus Mannerheim, 1843, Moskov. Obshch. Isp. Prirody Otd. Biol. Biul. (Bull. Soc. Imp. Nat. Moscou) 16:297 (Holotype, sex?; Sitka lsland, Alaska: Univ. Zool. Mus., Helsinki)
Dolurgus pumilus: Eichhoff, 1868, Berliner Ent. Zeitschr. 12:147
Diagnosis.- This distinctive species resembles the species of Crypturgus, but it is distinguished by characters included in the above generic key and description.

Male.- Length $1.6-1.9 \mathrm{~mm}, 2.7$ times as long as wide; color brown.

Frons broadly concave; surface subreticulate, punctures fine, deep, rather close; vestiture of fine hair, inconspicuous.

Pronotum 1.05 times as long as wide; widest just behind middle, sides moderately arcuate on posterior two-thirds, distinctly constricted on anterior third, rather narrowly rounded in front; surface reticulate, punctures rather coarse, moderately deep, rather abundant. Vestiture hairlike, inconspicuous.

Elytra 1.8 times as long as wide; sides almost straight and parallel on basal three-
fourths, rather narrowly rounded behind; striae feebly impressed, punctures coarse, rather deep; interstriae narrower than striae, a few indistinct, transverse lines, shining, very fine punctures forming an almost uniseriate row on lateral side of each discal interstriae. Declivity steep, convex; essentially as on disc. Vestiture of rows of very fine, short, strial and interstrial hair.

Female.- Similar to male.
Distribution.-Alaska to California.
ALASKA: Gold Creek Road at Juneau, Sitka Island. CANADA: British Columbia: Massett, Queen Charlotte Islands, Stanley Park, Vancouver. USA: California:

Crescent City, Del Monte, Inverness, Klamath in Del Norte Co., Montara, Monterey Co., Pacific Grove in Sonoma Co. Oregon: Astoria, Coos Bay, Gold Lake in Willamette N.F., Mary's Peak, Mt. Ashland, Newport, Santiam Pass. Washington: Hoquiam, Junction, Quillayute.

Hosts.- Abies nobilis, Picea engelmannii, P. sitchensis, Pinus contorta, P. muricata, P. radiata, and $P$. tuberculata.

Biology.- This species may enter the host through the entrance tunnel of another species, but evidently the habit is not obligatory. Their galleries resemble those of Crypturgus.

Notes. - The above treatment was based on the holotype and on 153 other specimens.

# Tribe XYLOTERINI 

Xyloteroideae Lindemann, 1876, Bull. Soc. Imp. Nat. Moscou 51:165 (Type-genus: Trypodendron Stephens, 1830
$=$ Xyloterus Erichson, 1836)
Trypodendrinae Trédl, 1907, Ent. Blätt. 3:18 (Type-genus: Trypodendron Stephens, 1830)

Anatomical features.- The frons is sexually dimorphic, with the male flattened or concavely impressed, the female is convex, the eye is completely divided, the antennal funicle is 4 -segmented, the club is unmarked by sutures and is usually pubescent to the base, in some species the base is sufficiently corneous to clearly indicate that it was derived from an obliquely truncate club, the pronotum is strongly declivous and asperate, with the anterior margin slightly modified in the male, the female proepimeron bears a mycetangium, the procoxae are contiguous, and in some species the male is slightly smaller than the female.

Biological features.- All are monogamous and xylomycetophagous. The male joins the female in the parental gallery. The eggs are deposited individually in niches that are enlarged by the larvae to a size sufficient to accommodate the adult beetle. Both larvae and adults feed primarily upon the spores of symbiotic fungi. Reproduction is always bisexual.

Taxonomy.- Trypodendron occurs in Eurasia and evidently reached North America recently. The endemic, monobasic Xyloterinus is scarcely separable from the Asiatic Indocryphalus and undoubtedly is also a recent addition to the North American fauna. This tribe was probably derived very early from the same basic stock that gave rise to the Xyleborini. The three genera that constitute the tribe are distinguished from one another with some difficulty due to the intermediacy of Indocryphalus; the two North American genera are more easily recognized.

## Genus XYLOTERINUS Swaine

[^12]Diagnosis.- This genus is distinguished from the allied genera by the broadly and weakly procurved subcorneous basal area of the antennal club, and by the rather large, broad, transverse proepimeral excavation of the female.

Description.-Female distinctly larger than male. Frons convex in both sexes, although somewhat flattened in male. Antennal club with subcorneous basal area much thicker and broadly procurved. Pronotum subcircular, with anterior margin strongly procurved and armed in both sexes; foveate excavation on proepimeral area of the female rather long and broad, transverse. Elytra with punctures of striae and interstriae distinct; declivity convex. Anterior tibia flattened, with posterior face smooth in both sexes.

Distribution.- E North America; one species is known.

Biology.- The habits are essentially as in Trypodendron except that two rows of larval cradles occur above and two below the parental gallery. The hosts are mostly deciduous trees.

Notes.- This genus is very closely related to Indocryphalus Eggers, from eastern Asia, but it differs in having the antennal club indistinctly subtruncate and the female proepimeral excavation transverse. In Indocryphalus the club is of uniform thickness and densely pubescent to its båse, and the proepimeral excavation is longitudinal.

## Xyloterinus politus (Say)

Fig. 177, 178
Bostrichus politus Say. 1826, J. Acad. Nat. Sci. Philadelphia 5:256 (Syntypes; eastern United States; all types lost)
Xyloterinus politus: Swaine, 1918, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(2):83.
Xyloterus unicolor Eichhoff, 1872, Berliner Ent. Zeitschr. 15:136 〈Syntypes?; female; Wisconsin;
presumably lost with Hamburg Mus.); Wood, 1957, Canadian Ent. 89:353. Synonymy
Female.- Length $3.3-3.7 \mathrm{~mm}, 2.7$ times as long as wide; body color dark brown.

Frons convex, a weak transverse impression just above epistoma, and a feeble median elevation from epistoma to upper level of eyes; surface of epistoma smooth and shining, reticulate and sparsely, rather coarsely granulate above; vestiture sparse, fine, rather long. Eye completely divided, subequal halves separated by a distance equal to width of upper half; finely granulate. Antennal scape rather long; funicle 4 -segmented; club as long as scape, oval, basal area thicker, subcorneous and, on anterior face, broadly procurved.

Pronotum very slightly wider than long ( 1.02 times); sides feebly arcuate on basal two-thirds, subcircularly rounded in front; anterior margin armed by four teeth; asperities decreasing in size posteriorly, very fine and rather sparse behind summit; surface of posterior and lateral areas reticulate, shallowly, rather finely punctured; vestiture inconspicuous, fine, short, sparse. Proepimeral excavation rather large, about four times as long as wide, long axis transverse, extending from posterolateral coxal margin more than two-thirds of distance toward sharply margined posterolateral angles of disc.
Elytra 1.7 times as long as wide, sides subparallel on basal two-thirds, rather broadly rounded behind; striae not impressed, punctures small, distinctly impressed; interstriae two to three times as wide as striae, smooth, punctures about half as large as those of striae, shallow, in irregular rows. Declivity rather steep, convex; striae weakly impressed, punctures somewhat larger than on dise; costal margin sharply raised near apex. Vestiture consisting of sparse, fine, hairlike setae; short on disc, longer and more abundant on declivity.

Male.-Similar to female except length $2.7-2.9 \mathrm{~mm}, 2.4$ times as long as wide; frons more strongly impressed from epistoma to above eyes, only feebly convex; teeth on anterior margin of pronotum usually reduced in size, sometimes obsolete; and proepimeral excavation poorly developed and smaller. Male genitalia as figured.

Distribution.- Minnesota and New Brunswick to Mississippi and N Florida.

CANADA: New Brunswick: Fredericton. Ontario: Hastings Co., Ottawa, Ridgeway, Toronto. Quebec: Chelsea, Granby, Ile Perrot, Lac Tremblant Nord, Montreal, Mt. Orford, Plessiville, Quebec, Ste. Anne de Bellevue, Ste. Hilaire. USA: Connecticut: Litchfield, New Canaan. District of Columbia: Washington. Georgia: Haivasee. Illinois: Champlain. Kentucky: Cumberland St. Pk., Louisville. Maine: Brunswick, Orono. Maryland: Bladdensburg, Plummer's Island. Massachusetts: Cambridge, Framingham, W Springfield, Sherborn. Michigan: Detroit, Grand Ledge. Mississippi: luke. Minnesota: Itasca Park, Hennepin Co., Washington Co. New Hampshire: Claremont, Waterville, Webster. New Jersey: Axton, Boonton, Clemonton, Morristown, Ft. Lee, Middlesex Co., Hopatcong, Montclair, Orange Mts. New York: Brooklyn, Buffalo, Catskill Mts., Cranberry Lake, Ithaca, Pelham, Lacey, New Rochelle, Syracuse, West Point. North Carolina: Pink Beds. Ohio: Ashland, Cleveland, Delaware Co., Franklin Co., Hocking Co., Ira in Summit Co., Lake Co., Lake Winola, Orrville, Pickaway Co., Scioto Co., Wooster. Pennsylvania: Angora, Burning Wells, Castle Rock, Charter Oak, Frankford, Germantown, Harrisburg, Hummelstown, Inglenook, Laport, Lawndale, Lehigh Gap, Mt. Alto, Peck's Pond, Perry Co., Rickets, Roxborough, Sommerset Co., Sweden Valley, Tinicum. Virginia: Jones Creek. West Virginia: Bayard, Grant Co., Hancock Co., Little Falls, Monongalia Co., Morgantown, Pendleton Co., Raleigh Co., Randolph Co., Taylor Co., Wood Co. Wisconsin: Antigo, Clintonville, Madison, Prince Edward Co.

Hosts.- Various species of Acer, Alnus, Betula, Carya, Castanea, Fagus, Fraxinus, Quercus, Picea, Pinus, Tsuga, and Ulmus; rare in the coniferous hosts.

Biology.-As described for the genus.
Nores.- The identity of this species is based on the Fitch and LeConte specimens that apparently were compared to the types of politus. The synonymy of unicolor was based on a study of the Eichhoff descriptions and Eichhoff's (1878) statement that politus and its description were unknown to him. About 400 specimens were examined.

## Genus TR YpODENDRON Stephens

Trypodendron Stephens, 1830, Illustrations of British Entomology, Mandibulata 3:353 (Type-species: Dermestes domesticus Linnaeus, subsequent designation by Westwood, 1838 (1840), Synopsis of the Genera of British Insects, p. 39)
Xyloterus Erichson, 1836, Archiv Naturgesch. 2(1):60 (Type-species: Bostrichus lineatus Olivier, subsequent designation by Thomson, 1859, Skandinaviens Coleoptera synoptiskt bearbetade 1:146); Eichhoff, 1878, Mém. Soc. Roy. Sci. Liége (2)8:412. Synonymy

Diagnosis.- This genus is distinguished from Xyloterinus Swaine by the strongly,
narrowly procurved subcorneous basal area of the antennal club, by the inflated, tuberculate posterior face of the female protibiae (in the male it is flat and finely tuberculate), by the deeply, concavely excavated male frons, by the subquadrate male pronotum, and by the longitudinal proepimeral excavation in the female.

Description.- Length $\quad 2.7-4.6 \mathrm{~mm}$, 2.5-2.6 times as long as wide; color brown to black or bicolored.

Frons dimorphic, convex in female, extensively, deeply concave in male; eye completely divided into two parts; antennal scape elongate, funicle 4 -segmented, club with subcorneous basal area strongly, narrowly procurved; pronotum subcircular in female, subquadrate in male, anterior margin armed or not; female proepimeral excavation longitudinal. Scutellum present. Elytra feebly striate, interstrial punctures usually obsolete,
declivity convex, usually feebly sulcate, subapical costal margin sharply elevated. Anterior tibia subinflated and rather coarsely asperate on posterior face in female, flattened and finely asperate in male.

Distribution.- America north of Mexico, N Asia and Europe; about a dozen species are known; five species occur in North America.

Biology.- These monogamous ambrosia beetles attack the bole of unthrifty or dying trees larger than 10 cm in diameter. The entrance tunnel is formed by the female before the arrival of the male. It penetrates the bark and continues into the sapwood, where it may branch several times. The larvae are reared in cradles that are arranged in single series above and below the parental gallery. These cradles are enlarged by the larvae as they grow and serve as pupation chambers when the larvae are mature.

1. Pronotum asperate over entire surface, inchuding posterolateral areas; elytral striae with punctures regular, rather deep, sharply defined on both disc and declivity; Minnesota and New York to Arkansas and Mississippi; Pinus, Tsuga; $3.5-4.1 \mathrm{~mm}$ 1. scabricollis (LeConte)

- Pronotum with posterolateral areas punctate; elytral striae rather obscure, punctures very shallow, usually visible but not sharply defined on either dise or declivity
2(1). Frons of male armed by a rather large, sharply pointed, median tubercle between upper halves of eyes; posterolateral areas of pronotum more closely and deeply punctured (particularly on females); pronotum dark brown to black in color; mature color of elytra dark brown to black, usually with a pale area extending from elytral base to declivital margin between interstriae 2 and 7; surface of pronotum and elytra minutely reticulate; N Idaho, Manitoba, and Quebec to South Dakota and New Jersey; Betula, Alnus; 2.7-3.5 mm
- Frons of male without a tubercle at center; posterolateral angles of pronotum very finely, less closely punctured (particularly on females); color pattern variable, pronotum often with at least part of basal area pale3

3(2). Larger; female pronotum usually not asperate on median area at base; mature color black, young adults pale on an are between interstriae 2-7 from base to declivital margin and continuing on sides of declivity between interstriae 5-7 from base to apex; surface of elytra smooth, shining; Alaska and New Brunswick to California, New Mexico, and West Virginia; Populus; male $3.6-4.3 \mathrm{~mm}$, female 3.8-4.6 mm

> Smaller, males $2.7-3.3 \mathrm{~mm}$, females $3.0-3.7 \mathrm{~mm}$; median area of pronotum asperate to basal margin on both sexes; color variable, but almost never uniformly black; from coniferous hosts ....................................................................

4(3). Elytral surface smooth, shining, interstriae usually very minutely and irregularly punctured; elytra more broadly rounded behind, declivity abrupt, and subapical margin appearing broadly rounded from above; color dark brown to almost black, with pale yellowish brown markings on base of pronotum and on elytra on interstriae 2-4, 7, and on declivity (five dark alternating with four pale longitudinal stripes); transition in color from light to dark abrupt; Alaska and Newfoundland to California, New Mexico, and North Carolina; coniferous hosts; 2.7-3.5 mm 4. lineatum (Olivier)

- Elytral surface rather dull, minutely reticulate; elytra more narrowly rounded behind, declivity not as steep, subapical raised margin appearing subacuminate from above; color brown, anterior and lateral areas of pronotum and sides of elytra usually a darker brown, transition from light to dark gradual; Yukon and New Brunswick to California and Minnesota; Pinus banksiana and P. contorta; $2.9-3.7 \mathrm{~mm}$ 5. rufitarsus (Kirby)

## 1. Trypodendron scabricollis (LeConte) Figs. 177, 178

Xyloterus scabricollis LeConte, 1868, Trans. Amer. Ent. Soc. 2:158 (Holotype, male; Washington, D.C.; Mus. Comp. Zool., 991).
Trypodendron scabricollis: Provancher, 1878, Additions et corrections à la faune coléoptèrologique de la Quebec, p. 13, also 1878, La Nat. Canad. 10:381.
Diagnosis.- This species is distinguished by the finely, sparsely asperate posterolateral areas of the pronotum, by the sharply impressed strial punctures, by the smooth and shining elytral surface, and by the coloration.

Female.- Length 3.6-4.1 mm, 2.5 times as long as wide; body brown, basal one-fourth of pronotum and elytra between interstriae 2-7 usually somewhat lighter in color.

Frons convex, weakly impressed above epistoma; a short, broad carina on lower half reaching epistomal margin; surface rather coarsely granulate; vestiture moderately long, sparse, inconspicuous. Antennal club oval, with mediodistal margin very slightly produced.

Pronotum 0.90 times as long as wide; sides weakly arcuate and converging toward broadly rounded anterior margin; anterior margin armed by four teeth, median pair larger; asperities on anterior slope decreasing in size posteriorly to basal margin; posterolateral areas usually finely punctateasperate; vestiture sparse, inconspicuous.

Elytra 1.7 times as long as wide; sides subparallel on basal two-thirds, rather narrowly rounded behind; strial punctures sharply,
deeply impressed on both dise and declivity; interstriae more than twice as wide as striae, surface smooth, shining, with extremely minute, rather abundant, confused punctures (visible at a magnification of 70 diameters or more). Declivity convex, moderately steep; strial punctures as on disc, but usually a little smaller; interstriae 2 impressed, narrower than 1 or 3 ; subapical margin giving elytra a subacuminate appearance when viewed from above. Vestiture visible only on declivity, very short.

Male.-Similar to female except 3.5-3.7 $\mathrm{mm}, 2.3$ times as long as wide; frons broadly excavated from epistoma to vertex, more or less foveate at center in most specimens, lateral margins ornamented by longer, more abundant hair; pronotum subquadrate, 0.71 times as long as wide, anterior margin straight and unarmed.

Distribution. - Minnesota and New York to Arkansas and Mississippi.

USA: Arkansas: Jasper, Pulaski Co. Maine: Agricultural Experiment Station. Minnesota: Cass Lake, Ely. Mississippi: State College (Starkville), Trimcane Swamp. New Jersey: Brown's Mills Junction, Grenlock, Iona, Lahaway. North Carolina: Asheville, Durham, Pisgah Ridge, Tryon. Pennsylvania: Hazelton, Mit. Alto, North Mt. Virginia: Gloucester. West Virginia: Davis, Dellslow, Monongalia Co., Morgantown, Pocahontas Co.

Hosts.- Pinus banksiana, P. echinata, P. resinosa, P. taeda.

Biology.-Cut, unthrifty, or dying trees are selected for attack. The habits are essentially as described for the genus.

Fig. 177. Trypodendron, Indocryphalus, Xyloterinus spp.: 1-6, lateral or sublateral aspects of body, pronotum, or declivity of 1 , X. politus; 2, 5, female and 4, male T. lineatum, 6,I. aceris; 7-9, posterior face of protibia of 7, male lineatum, 8, female lineatum, 9, female X. politus; 10-11, male frons of 10, T. betulae, 11, X. politus; 12-16, anterior or lateral face of antenna of 12 , male T. rufitarsis, 13, 15, female T. rufitarsis, 14, 16, female X. politus; 17-22, male genital capsule, dorsal aspect of 17, T. betulac, 18, T. retusum, 19, T. lineatum, 20, T. rufitarsis, 21, T. scabricollis, 22, X. politus. (After Wood 1957:339.)

Notes. - The above treatment was based on the holotype and on 166 other specimens.

## 2. Trypodendron betulae Swaine <br> Figs. 176, 177, 178

Trypodendron betulae Swaine, 1911, Canadian Ent. 43:216 (Lectotype, male; Ste. Anne de Bellevue, Quebec; Canadian Nat. Coll., 9288, designated by Bright, 1967, Canadian Ent. 99:679)
Diagnosis.- This species is distinguished by the more coarsely punctured posterolateral areas of the pronotum, by the dull, minutely reticulate surface of the pronotum and elytra, by the color pattern of the mature beetle, by the presence of a rather large, sharply pointed median frontal tubercle between the upper halves of the eyes of the male, and by the distinctive male genitalia.

Female.- Length 3.1-3.5 mm, 2.6 times as long as wide; body color dark brown to black, with a pale yellowish brown area between interstriae 2 and 7 extending from base to declivital margin (pale area larger or smaller depending on age of specimen).

Frons convex, a weak transverse impression just above epistoma; a broad, low median carina extending from epistoma almost to upper level of eyes; surface rather coarsely and sparsely granulate; vestiture sparse, inconspicuous. Antennal club oval, symmetrical in outline.

Pronotum 0.90 times as long as wide, slightly wider than elytra; sides feebly arcuate and indistinctly converging on posterior half; anterior margin armed by two rather large and two small median teeth; asperities decreasing in size posteriorly to base; surface of posterolateral area minutely reticulate and punctured, punctures comparatively coarse, close, some of them subgranulate; vestiture sparse, short, inconspicuous.

Elytra 1.7 times as long as wide, sides straight, subparallel on basal two-thirds; striae indicated by indistinct, feebly impressed punctures; surface rather dull, appearing minutely reticulate (magnification at least 70 diameters). Declivity convex, moderately steep, interstriae 2 narrower than 1 or 3 and rather strongly impressed; interstriae 1 and 3 sometimes bearing a few minute granules; subapical margin a raised line appearing rather narrowly rounded from above.

Male.-Similar to female except 2.7-3.4 $\mathrm{mm}, 2.2$ times as long as wide; frons broadly
excavated from epistoma to vertex, a median carina at center ending dorsally between upper halves of eyes in a rather large, pointed tubercle; lateral margins of frontal excavations ornamented by more numerous, longer hairs; pronotum subquadrate, 0.67 times as long as wide, anterior margin straight, unarmed.

Distribution.- British Columbia and Quebec to South Dakota and New Jersey.

CANADA: Manitoba: Aweme. Ontario: Black Sturgeon Lake, Ottawa, Rockcliffe. Quebec: Chelsea, Gaspé Co., Ile Perrot, Laniel, Lac Tremblant, Montebello, Ste. Anne de Bellevue. Bright (1976:118) adds British Columbia, Alberta, Northwest Territories, New Brunswick, Nova Scotia. USA: Idaho: Sandpoint. Maine: Cupsupic. Massachusetts: Arlington, Cambridge. Minnesota: Itasca Park. New Hampshire: Mt. Washington, Waterville, Webster. New Jersey: Springfield. New York: Cranberry Lake. South Dakota: Savoy in Lawrence Co. Wisconsin: Clintonville.

Hosts.- Betula lenta, B. papyifera.
Biology. - Specimens were taken from unthrifty, standing trees larger than 10 cm in diameter. The habits are as described for the genus.

Notes.- The above treatment was based on the type series and on 262 other specimens.

## 3. Trypodendron retusum (LeConte) Figs. 177, 178

Nyloterus retusus LeConte, 1868, Trans. Amer. Ent. Soc. 2:158 (Holotype, male; Canada; Mus. Comp. Zool., 992)
Trypodendron retusum: Swaine, 1913, Rept. Ontario Ent. Soc. 43:89.
Diagnosis.- This species is distinguished by the larger size, by the smooth and shining surface of the elytra, by the coloration, by the absence of asperities in the median basal area of the female pronotum of most specimens, and in the male by the genitalic chracters.

Female.- Length 3.8-4.6 mm, 2.5 times as long as wide; body color uniformly black when fully mature, young adults with pale yellowish brown areas at base of pronotum and on elytra between interstriae 2-7 from base to declivital margin and continuing on sides of declivity between interstriae 5-7 to apex, extent of pale areas depending upon age of specimen.

Frons convex, moderately impressed above epistoma, with a short, broad, rather
indefinite median carina above epistoma; surface rather coarsely, sparsely granulate; vestiture sparse, rather long, inconspicuous. Antennal club oval, with mediodistal portion very slightly produced.

Pronotum 0.83 times as long as wide; sides weakly arcuate, anterior half of pronotum semicircularly rounded; anterior margin armed by four teeth, median pair larger; asperities decreasing in size posteriorly to behind summit, very finely, sparsely asperate in basal area (basal area entirely devoid of asperities in about two-thirds of available specimens); posterolateral areas feebly reticulate, finely and sparsely punctured, punctures not at all granulate; vestiture rather short, inconspicuous.

Elytra 1.7 times as long as wide; sides subparallel on basal two-thirds, narrowly rounded behind; strial punctures very fine, rather indistinctly, shallowly impressed; interstriae smooth and brightly shining, with extremely minute, rather abundant, confused punctures (visible at a magnification of 40 or more diameters). Declivity convex, moderately steep; strial punctures reduced; interstriae 2 impressed and narrower than 1 or 3 ; subapical margin sharply elevated and produced on a small portion at apex, giving the elytra a subacuminate appearance from above. Vestiture sparse, short, fine.

Male.-Similar to female except 3.6-4.3 $\mathrm{mm}, 2.3$ times as long as wide; frons broadly excavated from epistoma to vertex, lateral margins ornamented by longer, more abundant hair; pronotum subquadrate, 0.67 times as long as wide, anterior margin feebly recurved, unarmed, asperities extending to base of median area.

Distribution.-Alaska and New Brunswick to California, New Mexico, and West Virginia.

CANADA: Alberta: Cypress Hills, Edmonton, Medicine Hat. British Columbia: Bowman Lake, Kaslo, Quamechan Lake on Vancouver lsland. Manitoba: Aweme, Riding Mt. N.P. New Brunswick: Bathurst, Fredericton, Oak Bay. Ontario: Ottawa, Sudbury. Quebec: Ft. Coulonge, Ile Perrot, Laniel, Ste. Anne de Bellevue. Saskatchewan: Indian Head. Bright (1976:119) adds Alaska, Yukon. USA: Arizona: Grand Canyon. California: Chester, Lassen N.P., Plumas Co. Colorado: Pagos Springs in Hinsdale Co., Norwood in Montrose Co., Cheyenne Canyon. Connecticut: Hampton. Idaho: Priest River. Michigan: Huron Mts. Minnesota: Hennepin Co., Itasca Pk., Lake Co. Nevada: Baker. New

Hampshire: Webster. New Mexico: Cloudcroft. New York: Elka Park, Forestburg, West Point. Oregon: Fort Klamath, Klamath Falls. Pennsylvania: Promised Land. South Dakota: Cheyenne Crossing in Lawrence Co., Hill City. Utah: Logan Canyon, Payson Canyon, Long Hollow in Dixie N.F. Vermont: Hancock. Washington: Seattle. West Virginia: Dellslow, Morgantown. Wiscon$\sin$ : Dane Co.

Hosts.-Populus deltoides, P. grandidentata, P. tremuloides.

Biology.- Unthrifty standing trees larger than 10 cm in diameter are usually selected for attack. The habits are essentially as described for the genus.

Notes.- The above treatment was based on the holotype and on 362 other specimens.

## 4. Trypodendron lineatum (Olivier) <br> Figs. 177, 178

Bostrichus lineatus Olivier, 1795, Entomologie ou histoire naturelle des insects, Coleoptera 4(77):18 (Syntypes; northern Europe; d'Orey Coll., Paris Mus.?)
Trypodendron lineatum: Eichhoff, 1878, Mém. Soc. Roy. Liége (2)8:417
Apate bivittata Kirby, 1837, in Richardson's Fauna Bo-reali-Americana 4:192 (Lectotype, female; Boreal America; British Mus. Nat. Hist., present designation); Wood, 1957, Canadian Ent. 89:349. Synonymy
Bostrichus cavifrons Mannerheim, 1843, Bull. Soc. Imp. Nat. Moscou 16:297 (reprint p. 125) (Syntypes, male; Sitka Island; Univ. Zool. Mus., Helsinki); Wood, 1969, Great Basin Nat. 29:114. Synonymy
Trypodendron vittiger Eichhoff, 1880, Die europäischen Borkenkäfer, p. 298 (Syntypes?; California; presumably lost with Hamburg Mus.); Schwarz, 1886, Ent. Amer. 2:41. Synonymy
Trypodendron borealis Swaine, 1917, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(1):21 (Lectotype, female; Athabasca Landing, Alberta; Canadian Nat. Coll., 9289, designated by Bright, 1967, Canadian Ent. 99:679); Wood, 1957, Canadian Ent. 89:349. Synonymy
Diagnosis.- This species is distinguished by the smooth, shining elytral surface, by the steeper elytral declivity, with the raised subapical margin appearing broadly rounded when visible from above, by the coloration, and in the male by the genitalic characters.

Female.- Length $3.0-3.5 \mathrm{~mm}, 2.5$ times as long as wide; body color very dark brown to black, with base of pronotum and interstriae 2-4 and 7-8 light yellowish brown to dark brown, transition from light to dark color abrupt, pale areas quite variable in extent, apparently depending upon the age of the

Fig. 178. Trypodendron and Xyloterinus spp., dorsal aspect of males and females: 23-24, T. scabricollis, 25-26, T. retusum, 27-28, T. betulae, 29-30, T. lineatum, 31-32, T. rufitarsis, 33-34, X. politus. (After Wood 1957:341.)
specimen as well as other factors (presumably environmental).

Frons convex, weakly impressed above epistoma, with a short, broad, rather indefinite median carina above epistoma; surface reticulate, with rather fine, sparse granules; vestiture fine, rather long, inconspicuous. Antennal club oval, with mediodistal angle slightly produced.

Pronotum 0.83 times as long as wide; sides weakly arcuate, rather broadly rounded in front; anterior margin unarmed, several irregularly placed submarginal asperities present; asperities decreasing in size posteriorly to base; posterolateral area finely reticulate, with sparse, fine, shallow punctures; vestiture fine, sparse, inconspicuous.

Elytra 1.6 times as long as wide; sides subparallel on basal two-thirds, rather broadly rounded behind; strial punctures very fine, rather indistinctly, shallowly impressed; interstriae smooth, shining, with extremely minute, rather abundant, confused impressed points (magnification 40 diameters or more). Declivity convex, steep; strial punctures reduced; interstriae 2 weakly impressed, slightly narrower than 1 or 3; subapical margin sharply elevated, scarcely or not at all visible from above, outline, when visible, appearing broadly ronnded from above. Vestiture sparse, short, fine.

Male.-Similar to female except 2.7-3.2 $\mathrm{mm}, 2.4$ times as long as wide; frons broadly excavated from epistoma to vertex, lateral margins ornamented by longer, more abundant hair; pronotum subquadrate, 0.71 times as long as wide, anterior margin straight, unarmed.

Distribution.- Alaska and Newfomndland to New Mexico and North Carolina; Europe and N Asia.

ALASKA: Numerous localities. CANADA: Alberta, British Columbia, Manitoba, New Brunswick, Newfoundland. Nova Scotia. Ontario, Quebec, Saskatchewan. USA: Arizona, California, Colorado, Connecticut, District of Columbia, Idaho, Maine, Michigan, Minnesota, Montana, Nevada, New Hampshire, New Mexico, New York, North Carolina, Oregon, Pennsylvania, South Dakota, Tennessee, Utah, Washington, West Virginia, Wyoming.

Hosts.- Virtually all species of Abies, Larix, Picea, Pinus, Pseudotsuga, Thuja, Tsuga; rare in Alnus, Betula, Malus, and Juniperus.

Biology.- Felled, injured, and unthrifty trees larger than 10 cm in diameter are selected for attack. The habits are as described for the genus.

Notes.- Of the two syntypes used to describe Apate bivittata only the female remains in the British Museum (Natural History). That female is here designated as the lectotype of Kirby's species. The above treatment was based on the lectotype of bizattata, on all known syntypes of cavifrons, on Swaine's syntypes of borealis, on more than 50 European and Asian lineatum, and on more than 4,600 North American specimens.

## 5. Trypodendron rufitarsis (Kirby)

Figs. 177, 178

Apate rufitarsis Kirby, 1837, in Richardson's Fauna Boreali-Americana 4:193 Lectotype, male; Boreal America; British Mus. Nat. Hist., present desiqnation)
Trypodendron rufitarsis: Swaine, 1917, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(1):22.
Trypodendron ponderosae Swaine, 1917. Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(1):22 (Lectotype, female; Peachland, British Columbia: Canadian Nat. Coll., 9290, designated by Bright, 1967. Canadian Ent. 99:679); Wood, 1957, Canadian Ent. 89:351. Synonymy
Diagnosis.- This species is distinguished by the dull, finely reticulate surface of the elytra, by the coloration, by the narrowly rounded posterior outline of the elytra, by the unarmed anterior margin of the female pronotum, and in the male by the genitalic characters.

Female.- Length $3.4-3.7 \mathrm{~mm}, 2.6$ times as long as wide; body color brown, anterior and lateral areas of pronotum and sides of elytra usually a darker brown, transition from light to dark color gradual.

Frons convex, weakly impressed above epistoma, with a short, broad, rather indefinite median carina above epistoma; surface reticulate, with rather fine sparse granules; vestiture fine, rather long, inconspicuous. Antennal club oval, with mediodistal angle slightly produced.

Pronotum 0.83 times as long as wide, sides weakly arcuate, rather broadly rounded in front; anterior margin unarmed, several irregularly placed submarginal asperities present; asperities on anterior slope decreasing in size posteriorly to base; posterolateral area
finely reticulate, with sparse, fine, shallow punctures scarcely perceptible; vestiture fine, sparse, inconspicuous.

Elytra 1.7 times as long as wide; sides subparallel on basal two-thirds, narrowly rounded behind; strial punctures very fine, rather indistinctly, shallowly impressed; interstriae dull, minutely reticulate (visible at a magnification of 70 diameters of more). Declivity convex, moderately steep; strial punctures smaller; interstriae 2 rather weakly impressed, narrower than 1 or 3 ; subapical margin sharply elevated, produced on apical portion, giving elytra a subacuminate appearance from above. Vestiture sparse, short, fine.

Male.-Similar to female except 2.9-3.2 $\mathrm{mm}, 2.5$ times as long as wide; frons broadly excavated from epistoma to vertex, lateral margins ornamented by longer, more abundant hair; pronotum subquadrate, 0.67 times as long as wide, anterior margin straight, unarmed.

Distribution.-Yukon and New Brunswick to California, Arizona, and Minnesota.

CANADA: Alberta: Laggan. British Columbia: Likely, Lorna, Midday Valley, Mt. Apex, Peachland,

Stanley, Trinity Valley. Manitoba: Riding Mt. N.P. New Brunswick: Maple Grove, Nictor Lake, "Pisequit Br." Ontario: Black Sturgeon Lake, Hymers. Bright (1876:122) adds Yukon. USA: Arizona: Flagstaff, Whiteriver. California: Fallen Leaf Lake, Lake Alpine, Medicine Lake, White Wolf, Yosemite N.P. Colorado: Newcastle, Pine River in La Platta Co., Pingree Park, Pitkin, Vallecito R.S. in La Platta Co. Idaho: Centerville, Lakeview, Minadoka N.F., Soda Springs. Minnesota: Ely. Montana: Beaverhead, Beaver N.F., Sula, Wisdom. Oregon: Blue Mts., Cable Cove, Detroit, Grant Co., Klamath Falls, Miami N.F., Pineville, Whitman N.F. Utah: Logan Canyon, Long Hollow in Dixie N.F., Mammoth Mt. Washington: Longmire, Metaline Falls, Olympia.

Hosts. - Pinus banksiana, P. contorta, and rare in P. jeffreyi, P. monticola, P. ponderosa, Picea engelmannii.

Biology.- Injured, unthrifty, or dying trees on dry to moderately dry sites are selected for attack; standing trees evidently are preferred. The habits are as described for the genus.

Notes.- The male syntype of rufitarsis that is labeled as the type in the British Museum (Natural History) is here designated as the lectotype of Kirby's species. The above treatment was based on the lectotypes of rufitarsis and ponderosae, and on 347 other specimens.

## Tribe XYLEBORINI

Xylebori LeConte, 1876, Proc. Amer. Philos. Soc. 15:358 (Type-genus: Xyleborus Eichhoff, 1864)
Webbinae Hopkins, 1915, U.S. Dept. Agric. Tech. Bull. 17(2):224 (Type-genus: Webbia Hopkins, 1915)

Anatomical features.- The male is dwarfed and moderately to strongly deformed, but most basic characters are as in the female. The frons is convex, the eye is emarginate (divided in Pseudoxyleborus, Asia), the antennal funicle is 5 -segmented (3-4-segmented in some Asiatic forms), the club is obliquely truncate (some Asiatic exceptions), the pronotum is declivous and asperate on the anterior half, its margins are rounded, the procoxae vary from widely separated to contiguous, and the meso- and metatibiae are rather broad, tapered to the apex on the apical third of their length, and armed by a rather large number of small, closely set, socketed denticles and setae.

Biological features.- All are consanguineously polygynous and xylomycetophagous. Eggs are deposited individually or in clusters in the parental galleries. The larvae may or may not extend the parental chambers. Both adults and larvae feed primarily on spores of symbiotic fungi. The haploid males are flightless and do not join the female in the formation of parental galleries. Facultative arrhenotokic parthenogenesis apparently is universal.

Taxonomy.-Some recent authors place virtually all representatives of this tribe in one genus. I believe a comprehensive world review of the group will reveal the existence of several well-defined genera, some of which are recognized below. The Xyleborini are primarily tropical, and most American groups are shared with other tropical areas. Except for introduced species, all North American forms appear to have been derived from tropical America rather recently. Earlier faunal exchanges may have involved Africa and, possibly, Australia.

Genus PREMNOBIUS Eichhoff
Premnobius Eichhoff, 1878. Mém. Soc. Roy. Sci. Liége
(2)8:65, 404 (Type-species: Premnobius
catipennis Eichhoff, monobasic); Browne, 1961, West African Timber Borer Research Unit Rept. 4:45-51 (Status of genus)
Diagnosis.- This genus is somewhat intermediate between the Ipini and Xyleborus. Although it is probably more closely related to Sampsonius Eggers than to Xyleborus, it is much more likely to be confused with the latter. From Xyleborus it differs by the rather strongly flattened antennal club that is pubescent to its base, at least at the sides, by the much more slender labial palpi, by the tuberculate posterior face of the protibiae (except in Dryocoetoides), by the simple larval spiracles, and by the presence of pupal cradles formed by the larvae in the gallery system.

Description.- Length, female 2.3-3.3 $\mathrm{mm}, 2.9$ times as long as wide; pale to rather dark reddish brown. Males much smaller.

Frons convex, conservatively sculptured; eye elongate, finely faceted, deeply, broadly emarginate. Antennal scape elongate; funicle 5 -segmented; club strongly flattened except at base, pubescent to base. Pregular area not depressed below ventral contour of head. Labial palpi slender, segment 3 not enlarged, segments subequal in length. Pronotum much longer than wide; summit anterior to middle; anterior margin unarmed. Elytra elongate, feebly striate; declivity obliquely truncate to deeply, broadly excavated, margins usually dentate. Protibiae tuberculate on posterior face, meso- and metatibiae of Xyleborus type. Anterior coxae subcontiguous. Pupal cradles formed by larvae.

Distribution.- Africa and Florida to Brazil; 16 African species; 2 of these also occur in America.

Notes. - Schedl (1957), followed by Bright (1968), treated this genus as a synonym of Xyleborus. Browne (1961) reviewed anatomical characters of both larvae and adults
and biological characters that clearly place Premnobius among the most primitive

Xyleborini and set them apart as a unique genus within the tribe.

## Key to the American species of Premnobius

1. Smaller; declivital interstriae 1 with a row of pointed tubercles; declivity occupying only 33 percent of elytral length; its lateral margin finely serrate, a slightly larger tubercle near middle, another on lower fourth; Africa, Florida to Brazil; 2.3-2.8 mm 1. cavipennis Eichhoff

- Larger; declivital interstriae 1 entirely unarmed; declivity occupying 43 percent of elytral length, its lateral margins each armed by four rather coarse tubercles on upper third and a much larger spine slightly below middle; Africa, Colombia to Brazil; $3.0-3.3 \mathrm{~mm}$
ambitiosus (Schaufuss)

## 1. Premnobius cavipennis Eichhoff

 Fig. 179Premnobius cavipennis Eichhoff, 1878, Mém. Soc. Roy. Sci. Liége (2)8:404 (Syntypes; Cap bonae spei in Africa meridionalis, and Colombia; lost with Hamburg Mus.)
Xyleborus industrius Sampson, 1912, Ann. Mag. Nat. Hist. (8) 10:248 (Holotype, female; Uganda; British Mus. Nat. His.); Schedl, 1962, Rev. Ent. Mocambique 5(1):538. Synonymy
Xyleborus xylocranellus Schedl, 1931, Ann. Mag. Nat. Hist. (10)8:344 (Holotype, female; Brazil; Schedl Coll.); Browne, 1961, West African Timber Borer Research Unit Rept. 4:50. Synonymy
Premnobius biturberculatus Eggers, 1932, Rev. Zool. Bot. Afr. 22:35 (Holotype, female; Region de Sassa, Congo; Tervueren Mus.); Schedl, 1962, Rev. Ent. Mocambique 5(1):538. Synonymy
Premnobius latior Eggers, 1933.3, Trav. Lab. d'Ent. Mus. Nat. d'Hist. Nat. Mem. 1:9 (Holotype, female; St. Jean de Maroni, French Guiana; Paris Mus.); Wood, 1977, Great Basin Nat. 37:210. Synonymy
Diagnosis.- This small, long, cylindrical species with the declivity deeply excavated is most easily recognized by the flattened, pubescent antennal club and rather abundant, short, fine pubescence. It is commonly attracted to light.

Female.- Length $2.3-2.8 \mathrm{~mm}, 2.9$ times as long as wide; color reddish brown.

Frons broadly convex, median line near center feebly elevated in most specimens; surface subreticulate, obscurely punctured above, some punctures replaced by very fine granules below upper level of eyes. Eye and antenna as described for the genus.

Pronotum 1.2 times as long as wide; sides almost straight and parallel on slightly more than basal half, rather broadly rounded in front; anterior margin unarmed; summit indefinite, slightly more than one-third
pronotum length from anterior margin; anterior slope steep, rather finely asperate; posterior areas smooth, shining, very finely, rather deeply, closely punctured; lateral margins subacute. Vestiture of fine, short, rather abundant hair.

Elytra 1.7 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal three-fourths, shallowly subemarginate on median third behind; striae not impressed, punctures minute, in scarcely definable rows; interstriae smooth, usually with numerous minute, obscure points, about six times as wide as striae, punctures small, confused, usually indistinguishable from those of striae. Declivity broadly, rather deeply, concavely excavated, on posterior third of elytra, lateral margins distinctly higher than suture; sutural interstriae with a row of fine, pointed tubercles; declivital face with rather large, moderately deep, confused punctures, shining; lateral margins on upper half with a row of minute denticles, a small tooth near middle; lower half with one to three minute denticles, a moderately large tooth on margin on lower fourth; lateral margin obsolete before apex. Vestiture of abundant, rather short, fine hair, somewhat longer and coarser at base of declivity.

Male.- Not seen; described by Browne (1961) as much smaller than female, with features less perfectly formed; elytral declivity much more gradual, less strongly excavated; flightless.

Distribution.- Florida to Brazil, and Africa.

USA: Florida: Plant City, 14-VII-39, at light, R. H. Beamer; Sanford, 8-VIII-39, at light, D. E. Hardy;

Fig. 179. Premnobius cavipennis: 1, male; 2-3, female; 4, female protibia; 5, female proventricular plate; 6, male genital capsule; 7 , female labium; 8 , female antenna; 9 , larval abdominal and thoracic spiracles; 10 , part of gallery system. (After Browne 1961:46.)

Miami, 6-VII-51, Rhizophora mangle, S. L. Wood. MEXICO: Chiapas: Valle de Ocosingo, 6-VII-51, L. J. Stannard. Veracruz: 18 miles ( 29 km ) E Coatzocoalcos, $26-$ Vl-67, 30 m, No. 104, tree limb, S. L. Wood. Yucatán: Chichen Itza, 30-VI-5I, L. J. Stannard. HONDURAS: La Ceiba, 29-V-49, at light, E. C. Becker; La Lima, Cortéz, 5-V-6.4, Sweitenia, S. L. Wood. OTHER AMERICAN COUNTRIES: Cuba, Puerto Rico, Jamaica, Venezuela, French Guiana, and Brazil.

Hosts. - Numerous tree species in Africa and South America.

Biology.- Unthrifty, fallen, or cut branches larger than 3 cm in diameter, limbs, or logs are selected for attack. The female constructs a radial tunnel about 3 cm into the wood; the tunnel may then branch or radiate palmately. Ambrosial fungus is cultured on the tumnel walls. The larvae develop in the tunnels, feeding upon the fungal growth until just before pupation, when each constructs its own pupation cell either above or below the parental gallery much as in many Platypodidae. About 11 to 17 pupal cradles occur in each gallery system. The young adults emerge through the parent entrance hole. Mating with the flightless males occurs before the female leaves the brood gallery.

Notes.- The above treatment was based on 53 American and 34 African specimens, several of which were compared to Eggers' homotypes. The types of industrius and latior were also examined.

## Premnobius ambitiosus (Schaufuss)

> Xylocleptes ambitiosus Schaufuss, I897, Berliner Ent. Zeitschr. $42: 109$ (Holotype, female; Gabun; repository unknown, but presumably lost with Hanburg Mus.)
> Premnobius cavipenis var. spinosus Hagedorn, 1908, Dentsche Ent. Zeit. 3:376 (Holotype, female; Kinchassa or Waellroek, Congo; Brussels Mus.) Eggers, I922, Ent. Blätt. I8:173. Synomymy
> Premnobius brasiliensis Nunberg, I958, Acta Zool. Cracoviensia 2:490 (Holotype, female; São Paulo, Brazil; Escola Nacional de Agronomia, São Paulo); Schedl, I960, Ent. Blätt. 56:107. Synonymy

This African species has been reported from Brazil and Bolivia, and I have a specimen from Sevilla, Valle de Cauca, Colombia, V-58, en gaumo, A. Duque V. It has not been reported from North or Central America, but at the present rate of dispersal it should soon reach Central America. In Africa it breeds in a wide variety of host plants.

It is very similar to cavipennis Eichhoff, but it is readily distinguished by the larger size and by the much larger declivital teeth. The identity of this species is based on the direct comparison of the holotypes of ambitiosus and spinosus by Eggers (1922), and by my comparison of Eggers's homotype to my specimens.

Genus SAMPSONIUS Eggers

Sampsonius Eggers, I933, Trav. Lab. Ent. Mus. Nat. d'Hist. Nat., Paris, Mém. 1:23 (nomen nudum); Eggers, 1935, Rev. de Ent. Río de Janeiro 5:158 (Type-species: Sampsonius sexdentatus Eggers. original designation)
Diagnosis. - The true affinities of this genus are uncertain, but it evidently is more closely allied to Premnobius than to other known genera, although the relationship is remote. It is distinguished by the unusually slender body, by the flattened antennal club that has two slightly procurved sutures on the anterior face and at least one strongly procurved suture on the posterior face, by the armed anterior margin of the pronotum in which two serrations are unusually large, by the gradual declivity with its remarkable structure, and by the habits.

Description.- Length, female 2.9-5.8 mm, 3.3-3.8 times as long as wide; rather light reddish brown. Male dwarfed, flightless.

Frons narrow, convex; eyes enlarged, emarginate, coarsely faceted; pregular area depressed; segment 1 of maxillary palpi slightly enlarged. Antennal scape elongate; funicle 5 -segmented; club rather strongly flattened, sutures 1 and 2 moderately to strongly procurved, at least one suture visible on posterior face. Pronotum elongate, summit well in front of middle, anterior slope asperate, anterior margin armed by two enlarged serrations, supplemented by smaller lateral serrations in some species. Scutellum moderately large, flat, fitted into sutural notch at base of elytra. Elytra elongate, weakly striate, declivity gradual, variously, often remarkably sculptured. Procoxae contiguous, intercoxal piece obsolete. Anterior tibiae slender, posterior face slightly inflated. Male dwarfed, anterior slope of pronotum impressed to excavated; declivity less strongly impressed, characters imperfectly formed.

Distribution.-S Mexico to Brazil; about 10 species are known; 4 occur from Chiapas to Panama.

Biology.- These species are ambrosia beetles. As with other Xyleborini, the males are flightless; therefore mating must occur in the brood chamber. The females are evidently incapable of excavating an entrance tunnel. They seek out a newly constructed tunnel of a Xyleborus species of appropriate diameter to accommodate their body and enter and often wait for the host to advance the tumnel adequately before clearing first one branch and then the other of eggs and young larvae; then they finally evict the host. Whether the host is removed forcibly or is repelled by offensive secretions or other factors was not
determined. The Sampsonius female then deposits clusters of eggs in the tunnels. The larvae excavate tabular extensions of the gallery with the grain of the wood in much the same fashion as does the host species. They are found in branches or seedlings about $2-8 \mathrm{~cm}$ in diameter; they are very rare.

Notes.- This genus evidently represents a primitive stock of the Xyleborini as indicated by the structure of the antenna, by the slightly enlarged segment 1 of the labial palpi , and by the scutellum. The total elimination of the prothoracic intercoxal piece, the unusually slender body form, and the unusual sculpture are probably adaptations to the domicile "parasitic" habit.

## Key to the Species of Sampsonius

1. Sutural interstriae on declivity flat to moderately elevated on apical fourth, but entirely devoid of an acute or abruptly extended process; larger species

2(1). Elytral declivity concave only on longitudinal axis, suture higher on apical third than lateral convexities; devoid of declivital spines; Colombia; 5.1 mm (see also 2. reticulatus Bright) ...............................................................expulsus Wood

- Elytral declivity almost straight on longitudinal axis, lateral convexities on apical third higher than suture; lateral area near apex of interstriae 3 bearing one long, slender spine; Panama; 5.6-5.8 mm
3(1). Larger; elytral declivity commencing at or slightly anterior to middle; declivity with lateral convexities on interstriae 3 slightly higher than suture, area from interstriae 3 to serrate lateral margin less strongly impressed; pair of spines near apex of sutural interstriae rather small, acute, their length equal to little more than width of an interstriae, their summits contiguous; Costa Rica to Panama; female $4.0-4.4 \mathrm{~mm}$

3. usurpatus Wood

- Smaller; elytral declivity commencing well behind middle; declivital suture as high as lateral convexities, area between convexities and serrate lateral margins much more distinctly impressed; process near apex of sutural interstriae variable, much larger, occupying about a fourth of declivital length, its height equal to width of $1-3$ interstriae, summits usually diverging from suture; Veracruz to Brazil; female 2.9-4.1 mm

4. dampfi Schedl

## 1. Sampsonius detractus Wood

 Fig. 180Sampsonius detractus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):31 (Holotype, female: Madden Forest. Canal Zone, Panama, Wood Coll.)

Diagnosis.- The large size and the presence of one pair of long, slender spines near the apex of declivital interstriae 3 distinguish this species from other representatives of the genus.

Female. - Length 5.6-5.8 mm, 3.6 times as long as wide; color reddish brown.

Frons narrow, broadly convex; surface reticulate, with small, low, rather abundant, shining granules; vestiture of sparse, fine, long hair. Eye large, emarginate, very coarsely faceted, 1.9 times as long as wide. Antennal club subcircular, rather strongly flattened, sutures 1 and 2 rather strongly procurved, 2 reaching slightly beyond middle; one strongly procurved suture near apex on posterior surface.

Pronotum 1.4 times as long as wide; sides feebly arcuate and subparallel on posterior two-thirds, narrowly produced on anterior third to two very coarse, close serrations arming anterior margin, two pairs of small serrations lateral to major ones; summit indefinite, about one-third pronotum length from anterior margin; anterior third moderately asperate; posterior areas smooth, shining, minutely, rather sparsely punctured; lateral margins abrupt. Vestiture of sparse, fine hair, slightly coarser and longer on asperate area.

Elytra 2.1 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal three-fourths, slightly narrowed, then truncate on median two-thirds; discal striae not impressed, punctures very small, distinct; interstriae smooth, shining, about four times as wide as striae, punctures
almost uniseriate, minute. Declivity occupying posterior 46 percent of elytral length, gradual basal margin abruptly impressed and irregularly, finely serrate from interstriae 1 to posterolateral apical angle; surface reticulate; sutural interstriae not elevated or armed; interstriae 3 posterior to middle broadly elevated and slightly higher than suture, descending to moderate impres sion just mesad of serrate lateral margin; armed just before apex of interstriae 3 by a pair of very large, subcylindrical spines, each four times as high as wide, equal in length to discal distance from suture to striae 4 . Vestiture of fine, moderately long hair on dise and sides, very much longer and slightly more abundant on declivity.

Distribution. - Panama.
Panama: Madden Forest, Canal Zone, 2-I-64, 70 m , No. 367, tree limb, S. L. Wood.

Biology.-As described for the genus.
Notes. - The above treatment was based on the type series of two females.

## 2. Sampsonius reticulatus Bright

Sampsonius reticulatus Bright, 1972, Canadian Ent. 104:1369 (Holotype, female; Dos Amates, Veracruz, Mexico, Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from expulsus Wood by the confused punctures on most discal interstriae and by the different elytral declivity as described below.

Fig. 180. Sampsonius spp., female declivity: A, detractus; B, usurpatus; C, dampfi.

Female.- Length 4.9-5.3 mm, 3.8 times as long as wide; color reddish brown to yellowish brown.

Frons, pronotum, and elytral disc as in expulsus. Declivity somewhat similar to expulsus except sutures less strongly elevated, ascending laterad from striae 1 to rather abrupt summit on 3,3 conspicuously higher than 1 , its crest extending from base almost to apex, 2 with a row of fine tubercles, 3 with similar tubercles more numerous and confused; setae much longer, more abundant, longest equal in length to distance on disc from suture to striae 5 .

Distribution.- Veracruz.
Mexico: Veracruz: Dos Amates, 5-V-69, D. E. Bright.

Notes.- The above treatment was based on the holotype and on five paratypes.

## 3. Sampsonius usurpatus Wood

Fig. 180
Sampsonius usurpatus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):32 (Holotype, female; Turrialba, Cartago, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from the closely allied dampfi Schedl by the larger size, by the longer elytral declivity, by the declivital suture being lower than the lateral convexities, and by the much smaller, contiguous spines near the sutural apex on the elytral declivity.

Female.- Length $4.0-4.4 \mathrm{~mm}$ (males $2.8-3.3 \mathrm{~mm}$ ), 3.8 times as long as wide; color reddish brown.

Frons as in detractus Wood except slightly narrower. Pronotum as in detractus.

Elytra 2.2 times as long as wide; outline as in detractus except tapered posteriorly, subtruncate on less than median half; disc and general contour of declivity as in detractus except basal margin gradual, denticles smaller, more scattered; apex of interstriae 3 entirely unarmed; sutural interstriae armed by contiguous, subapical, pointed processes about as high as their longitudinal base, height about equal to width of a discal interstriae, positioned as in dampfi but much smaller. Vestiture as in detractus.

Male.- Dwarfed, head concealed by prolongation of pronotum; pronotum longer than elytra, 1.7 times as long as wide, its
anterior three-fifths broadly, rather deeply concave, anterior margin narrowly biemarginate, giving appearance of a median and two lateral dentations; elytra similar to female but characters poorly formed, more convex, devoid of subapical spine.

Distribution.- Costa Rica to Panama.
COSTA RICA: Turrialba, Cartago, 9-111-64, 700 m , No. 460, tree seedling, S. L. Wood: San Ignacio de Acosta, 5-VII-63, 1500 m , No. 38, seedling, S. L. Wood; Finca Gromaco on Río Coto Brus, Puntarenas, 14-ViI$63,500 \mathrm{~m}$, No. 76, tree seedling, S. L. Wood; Rincón de Osa, Puntarenas, Il-VIII-66, 30 m , No. 68, tree branch, S. L. Wood. PANAMA: El Hato del Volcán, Chiriquí, 11-I-64, $28(\%) \mathrm{m}$, No. 374, tree branch, S. L. Wood.

Hosts.- Several tree species.
Biology.-As described for the genus. The scolytid host species apparently was Dryocoetoides capucinus (Eichhoff).

Notes.- The above treatment was based on the type series of 32 specimens; 25 were taken from one gallery; only 2 of them were males.

## 4. Sampsonius dampfi Schedl <br> Fig. 180

Sampsonius dampfi Schedl, 1940, An. Esc. Nac. Cienc. Biol., Mexico 1:359 Lectotype, female; Chiapas, Mexico; Schedl Coll., present designation)
Sampsonius costaricensis Numberg, 1963. Trans. Wiscon$\sin$ Acad. Sci. Arts. Let. 52:104 Lectotype, females; Finca La Lola, Limón, Costa Rica; Univ. Wisconsin Coll., present designation); Schedl, 1969, Turrialba 19:554. Synonymy
Diagnosis.- This species is distinguished from the allied usurpatus Wood by the smaller size and by the shorter elytral declivity, with different declivital sculpture.

Female. - Length 2.9-4.1 mm, 3.8 times as long as wide; color reddish brown.

Head, pronotum, and elytral dise as in detractus Wood. Elytral declivity 37 percent of elytral length. Elytral declivity as in usurpatus except suture on lower half as high or higher than lateral convexities, impression just mesad of serrate lateral margin distinctly stronger; lower fourth of sutural interstriae armed by a very large, strongly elevated, variable process, appearing triangular to rectangular from lateral aspect, frequently projecting beyond sutural apex, their crests diverging from suture. Vestiture as in detractus.

Distribution.- Veracruz to Brazil.

MEXICO: Chiapas: El Bosque, 3-VII-69, D. E. Bright; Finca Esperanza, I2-III-38, at light, A. Dampf; Finca Vergel, 7-VI-35, at light, A. Dampf. Veracruz: Sontecomepan, I8-VI-69, D. E. Bright. COSTA RICA: San Isidro del General, I2-XII-63, 1000 m , No. 3I3, tree branch, S. L. Wood; Playón, 9-VIII-63, 50 m , No. 120, Ochroma, S. L. Wood; Río Damitas, Dota Mts., I8-1I-64, 250 m , No. 436, tree seedling, S. L. Wood; Rincón de Osa, Puntarenas, 11-VIII-66, 30 m , No. 49, Vismia, S. L. Wood; Finca La Lola, Limón, 20-VII-6I, Theobroma cacao. PANAMA: Barro Colorado Island, Canal Zone, 17-VII-23, R. C. Shannon; Ciricito, Canal Zone, 3-III-30, R. E. Blackwelder; Concepción, Chiriquí, 7-1-64, 300 m , No. 370, Ochroma, S. L. Wood; Madden Forest, 2-I-64, 70 m , No. 364, tree branch, S. L. Wood; San José, Pearl Island, 26-VI-44, at light, J. P. E. Morrison. OTHER COUNTRIES: Colombia, Venezuela, Brazil.

Hosts.- Ochroma sp., Vismia sp., Theobroma cacao, and several other trees.

Biology.- As described for the genus. On four occasions Dryocoetoides capucinus (Eichhoff) was the invaded host; on one occasion a Xyleborus species formed the original gallery.

Notes.- The female syntype of dampfi Schedl in the Schedl Collection is here designated as the lectotype of dampfi, and the female syntype of costaricensis Nunberg in the University of Wisconsin Collection is here designated as the lectotype of costaricensis. The above treatment was based on both lectotypes and on 27 other specimens.

## Genus DR YoCOETOIDES Hopkins

Dryococtoides Hopkins, 1915, U.S. Dept. Agric. Rept. 99:52 (Type-species: Dryocoetoides quatemalensis Hopkins $=$ Xyleborus capucinus Eichhoff)
Diagnosis.- This genus is grouped with Sampsonius Eggers by the separate sutures 1 and 2 on the rather strongly flattened antennal club, with suture 2 attaining the apex and suture 1 continuing to and clearly visible on the posterior face of the club. It is easily distinguished from Sampsonius by the very difrerent body form, sculpture, and habits, and from Xylophilus by the inflated anterior tibia, with its posterior face armed by several granules or denticles, and by the somewhat larger, more coarsely faceted eyes.

Description.- Length 2.2-5.1 mm, 2.3-2.8 times as long as wide; color reddish brown.

Female frons convex, sculpture simple; eye rather large, elongate, deeply emarginate, moderately to very coarsely faceted. Antennal scape elongate; funicle 5 -segmented; club subcircular, moderately flattened, thickened basally, basal area subcorneous, sutures 1 and 2 clearly marked, 1 continuing to and clearly marked on posterior face, 2 continuing to apex of club. Pronotum 1.0-1.1 times as long as wide; summit at or near middle; anterior slope broadly convex, rather finely asperate; anterior margin armed by serrations; posterior areas smooth. Elytra elongate, weakly striate; interstrial punctures moderately to strongly confused; declivity convex, its lateral margin marked by crest or row of tubercles from sutural apex to interstriae 8. Protibiae inflated on posterior surface, inflated area armed by several coarse tubercles or small denticles, outer margin also armed by socketed teeth; meso- and metathoracic tibiae as typical of tribe. Male dwarfed, flightless, deformed, rare; head slightly modified; pronotum elongate, devoid of asperities, anterior half impressed to excavated, anterior margin acutely elevated on continuous crest to median tuberculate prominence; protibia not inflated or armed on posterior face.

Distribution.- Veracruz to Peru and Brazil; 12 species are at hand; 2 of them occur in Mexico and Central America.

Notes.- Except for its author, this genus has not been recognized, presumably because of the lack of material for study and the supposed absence of related forms sharing the generic characters. In addition to the typespecies, 11 South American species before me share the antennal and tibial characters of this genus. The habits resemble those of Xylosandrus and the godmani group of Xyleborus.

## Key to the Species of Dryocoetoides

1. Smaller; elytral disc occupying less than 40 percent of elytral length; declivital surface strongly reticulate, dull, strial punctures obscure to obsolete and interstrial granules confused; crenulations on declivital interstriae 8 usually extend to level of suture between abdominal sterna 1 and 2; Nayarit and Veracruz to Peru and Brazil; 2.2-2.6 mm
2. capucinus (Eichhoff)

#### Abstract

Larger; elytral disc occupying 50 percent of elytral length; elytral declivity mostly or entirely shining, with strial punctures distinctly, shallowly impressed and interstrial granules on 2-7 mostly uniseriate except near base; crenulations on declivital interstriae 9 rarely extend to level of suture between abdominal sterna 2 and 3; Veracruz to Colombia and Venezuela: 2.8-3.2 mm

2. monachus (Blandford)
3. Dryocoetoides capucinus (Eichhoff), n. comb.

Xyleborus capucinus Eichhoff, 1869. Berliner Ent. Zeitschr. 12:281 (Holotype. female; Guadeloupe Island: Brussels Mus.)
Xyleborus rufithorax Eichhoff, 1869. Berliner Ent. Zeitschr. 12:281 (Holotype. female: Brazil; Brussels Mus.); Wood, 1973, Great Basin Nat. 33:187. Synonymy
Dryococtoides guatemalensis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:52 (Holotype, female; Livingston, Guatemala; U.S. Nat. Mus., 76.33); Wood, 1966, Great Basin Nat. 26:31. Synonymy
Xyleborus capucinoides Eggers, 1941, Arb. Morph. Taxon. Ent. Berlin-Dahlem 8:104 (Holotype, female; Gourbevre, Guadeloupe Island, U.S. Nat. Mus., 60761); Wood, 1966, Great Basin Nat. 26:31. Synonymy
Diagnosis.- This species is distinguished from monachus (Blandford) by the smaller size, by the shorter elytral disc, by the strongly reticulate, dull elytral declivity, and by the very obscure, almost obsolete declivital striae.

Female.- Length 2.2-2.6 mm, 2.3 times as long as wide; color very dark brown to black.

Frons broadly convex; surface strongly reticulate, area below upper level of eyes rather closely, finely granulate; vestiture inconspicuous. Eye 3.5 times as long as wide, separated above by 3.0 times width of an eve.

Pronotum 0.96 times as long as wide; sides weakly arcuate on basal two-thirds, rather broadly rounded in front except weakly produced near median line; anterior margin armed by four moderately coarse teeth (two additional smaller denticles often present); summit at middle, rather broad; rather coarsely asperate on anterior slope; entire surface reticulate, including asperate area but not asperities; posterior area finely, closely, deeply punctured. Vestiture of fine, abundant, rather short hair.

Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; sides almost straight and parallel on basal half, bluntly pointed behind; disc occupying basal 40 percent; striae
scarcely evident, punctures very small, distinct, spaced by about two diameters of a puncture; interstriae almost smooth, shining; interstriae six to eight times as wide as striae, setiferous punctures slightly smaller than those of striae, strongly confused, moderately abundant. Declivity rather gradual, its entire surface reticulate; striae weakly impressed, punctures mostly obscure to obsolete; when visible, shallow and much larger than on disc; interstrial punctures replaced by fine, confused granules, sometimes uniseriate on apical half of 2 and $3 ; 8$ subcrenulately granulate from near base of declivity to sutural apex. Vestiture of rather abundant, moderately long hair, fine on disc, slightly coarser on declivity.

Male. - Length 2.2-2.5 mm; head and elytra about as in female but less perfectly formed; pronotum 1.4 times as long as wide, devoid of asperities, summit near base, middle third flattened on median half, anterior third deeply excavated to margins, anterior margin sharply elevated, with a median tuberculate prominence.

Distribution.- Nayarit and Veracruz to Peru and Brazil.

MEXICO: Michoacán: Zirimicuaro, 2-XI-80, 350 m , Inga, T. H. Atkinson. Nayarit: San Blas. Veracruz: Matías Romero. Tecolutla. GUATEMALA: Rodeo (Esquintla). Trece Aguas (Alta Verapaz). COSTA RICA: Tapantí and Turrialba (Cartago), Beverley, Limón, and Pandora (Limón), Dominical, Finca Gromaco on Río Coto Brus, and Rincón de Osa (Puntarenas), Río Damitas in the Dota Mts., and San lsidro del General (San José). PANAMA: Ft. Clayton and Madden Forest (Canal Zone), El Hato del Volcán (Chiriquî). COLOMBIA: Barbosa (Antioquia). OTHER AREAS: Guadeloupe, Brazil, Peru.

Hosts.- Inga sp., Miconia sp., etc.
Brology.-As described for Xylosandrus and the Xyleborus godmani group.

Notes.- The above treatment was based on the holotypes of capucinus, rufithorax, guatemalensis, and capucinoides, and on 102 other specimens.

## 2. Dryocoetoides monachus (Blandford)

Xyleborus monachus Blandford, 1898, Biol. Centr. Amer., Coleopt. 4(6):204 (Lectotype, male; Cerro Zunil, Guatemala; British Mus. Nat. Hist., present designation)
Diagnosis.- This species is distinguished from capucinus (Eichhoff) by characters summarized in the above key and in the diagnosis of capucinus.

Female.- Length 2.8-3.2 mm, 2.3 times as long as wide; color black.

Frons and pronotum essentially as in capucinus, with pronotal dise usually smooth and shining.

Elytra about as in capucinus except disc occupying basal 50 percent of elytra; surface of disc and upper half of declivity smooth, shining, lower declivity often dull, subreticulate in some specimens; interstrial granules on declivity mostly uniseriate; crenulations on interstriae 8 begin about middle of declivity.

Male.- Length 2.7-2.9 mm; essentially as in male capucinus.

Distribution.-Veracruz to Colombia and Venezuela.

MEXICO: Chiapas: Ocozocoautla, 2-VII-69, Palenque Ruins, 9-V-61, and Tapilula, 13-V-69, D. E. Bright. Veracruz: Lago Catemaco, 1-3-V-69, D. E. Bright. GUATEMALA: Cerro Zunil, G. C. Champion; Palín, Esquintla, 19-V-64, 350 m, No. 584, Inga, S. L. Wood; Chicacao, 21-V11-44, Cinchona, R. Penchur. COLOMBIA: 24 km W Barbosa, 18-VII-70, 1200 m , No. 696, Rubiaceae sapling, S. L. Wood. VENEZUELA: Rancho Grande, Pittier Nat. Pk., Aragua, 9-IV-70, 1100 m , No. 408 in tree seedling, No. 420 in Tabebuia, No. 479 in tree branch, S. L. Wood.

Hosts.- Inga sp., Tabebuia sp., etc.
Biology. - As in capucinus.
Notes.- The above treatment was based on the 2 male syntypes of monachus and on 31 females. The first syntype is labeled "type" and is generally considered to be the type; I here designate it as the lectotype of Xyleborus monachus Blandford. The lectotype ( 2.7 mm ) was compared to several males of capucinus ( $2.2-2.5 \mathrm{~mm}$ ) and to 2 of my Guatemalan females of monachus and several Guatemalan females of capucinus in order to fix the identity of this species. The possibility of intergradation between these two species was thought likely until both were taken from the same plant near Barbosa, Colombia.

## Genus XYLOSANDRUS Reitter

Xylosandrus Reitter, 1913, Wiener Ent. Zeit. 32(15 May Beiheft):80, 83 (Type-species: Xyleborus morigerus Blandford, monobasic)
Diagnosis.- This genus is distinguished from Xyleborus Eichhoff by the widely separated procoxae, between which the intercoxal piece is at least half as wide as a coxa and usually flat, and, in part, by the stout body with the broadly convex, unarmed elytral declivity, declivity commencing anterior to the middle. The elytra are only slightly longer than the pronotum.

Description.- Length, females 1.3-1.7 mm , males $1.0-1.6 \mathrm{~mm}$, female 1.9-2.3 times as long as wide, male slightly more slender; color light brown to black; vestiture hairlike. Males dwarfed, flightless.

Frons broad, convex, simple. Eye rather small, deeply emarginate, finely faceted. Antennal scape elongate; funicle 5 -segmented; club obliquely truncate, margin of basal corneous area strongly recurved, sutures not evident. Pronotum slightly wider than long, summit at or slightly behind middle; anterior margin armed. Scutellum large, flat, filling sutural notch at base of elytra. Elytra stout, only slightly longer than pronotum; weakly striate; declivity commencing at or in front of middle, broadly convex, unarmed, ventrolateral margin acutely margined from sutural apex to interstriae 7. Anterior coxae apparently touching head, widely separated by an intercoxal piece almost equal to half diameter of a coxa. Males rare, dwarfed, head largely withdrawn into prothorax; pronotum more broadly convex, anterior slope somewhat flattened, feebly asperate, anterior margin unarmed; elytra more evenly convex, all characters more poorly "formed, posterolateral margin not acutely elevated.

Distribution.- Pantropical, extending into warmer temperate regions in some areas; about 25 species; 6 of these occur in America; 2 may be endemic.

Biology.- Twigs and small branches of trees and small stems of other plants are selected for attack. Some species are exceedingly aggressive and can attack the most vigorous shoots of healthy living plants. Because the males are rare and flightless, females mate in the brood chamber before seeking a
new host. In the new host the female constructs an entrance tumnel either into the pith of small stems or in the wood to a depth of about $1-3 \mathrm{~cm}$, where a small cavity is formed. Here a small mass of eggs is produced. The larvae evidently feed on a
mixture of the ambrosial fungus cultured on the chamber walls and on host tissues obtained while enlarging the parent cavity. The life cycle is completed in about a month. The number of offspring per female is usually small.

## Key to Females of the Species of Xylosandrus

1. Elytra 1.0 times as long as wide, declivity commencing one-third elytral length from base; sides of elytra often almost devoid of punctures; mature color yellowish brown; Veracruz to Brazil; female $1.4-1.7 \mathrm{~mm}$
2. morigerus (Blandford)

- Elytra about 1.2 times as long as wide, declivity commencing at middle; sides of elytra clearly marked by strial rows; mature color dark brown to black
2(1). Declivital striae obsolete; declivital surface dull, with dense, confused, minute, uniformly distributed granules; elytral hair more abundant; Asia, Africa, Hawaii, South Carolina; 2.1-2.9 mm

2. crassiusculus (Motschulsky)

- Declivital striae with punctures clearly impressed, in rows; declivital surface shining, granules in sparse rows if present
3(2). Larger; strial setae on declivity entirely obsolete; declivital striae at least feebly impressed, interstriae very slightly convex; lllinois and Connecticut to Kentucky and Virginia; 2.0-2.3 mm

3. germanus (Blandford)

- Smaller, strial setae on declivity present, at least one-third as long as those of interstriae; declivital striae not impressed; interstriae flat
4(3). Slightly more slender, elytra 1.2 times as long as wide; elytra almost evenly arched from middle of disc to apex; hair on pronotal disc more generally distributed, slightly more abundant on a transverse row in median area at base; interstrial setae on declivity fine, pointed; Louisiana and Alabama to Florida, Hawaii, etc., female $1.4-1.7 \mathrm{~mm}$ 4. compactus (Eichhoff)
- Stouter, elytra 1.1 times as long as wide; elytra more abruptly arched from base of declivity to middle of declivity; pronotal disc glabrous except for rather dense median tuft of hair, its long axis longitudinal, extending from base about half distance to summit
5(4). Pronotal disc and sides mostly or entirely reticulate; interstrial setae on declivity fine, tapered to a sharp point, each about twice as long as distance between rows; S Florida, Guatemala to Venezuela; 1.3-1.5 mm
- Pronotal dise and sides brightly shining; interstrial setae on declivity rather coarse, each flattened on its distal half and blunt at its apex, about as long as distance between rows; Nayarit and Veracruz to Brazil; females $1.3-1.5 \mathrm{~mm} . .$. . 6. curtulus (Eichhoff)

1. Xylosandrus morigerus (Blandford)

Xyleborus morigerus Blandford, 1894, Insect Life 6:264 (Syntypes; probably New Guinea; British Mus. Nat. Hist.)
Xylosandrus morigerus: Reitter, 1913. Wiener Ent. Zeit. 32(15 Nay Beiheft):83

Xyleborus coffeae Wurth, 190s, Mededeel. Proefst. Salatiga, ser. 2. 3:2-20 (Not seen), Salatiga Cultuurgids 10:63-75 (Not seen); Schedl, 1951, Occ. Pap. Bishop Mus. 20:136. Synonymy
Xyleborus luzonicus Eggers, 1923. Zool. Meded. 7:174 (Lectotype, female; Mt. Makiling, Luzon, Philippines; U.S. Nat. Mus., designated by Anderson
and Anderson, 1971, Smithsonian Contrib. Zool. 94:18); Wood, 1974, Great Basin Nat. 34:287. Synonymy
Diagnosis.- This species is distinguished from other American representatives of this genus by the reddish brown color, by the stouter body, by the declivity commencing only one-third of the elytral length from the base, and by the near absence of punctures on the sides of the elytra (variable).

Female.- Length $1.4-1.7 \mathrm{~mm}, 1.9$ times as long as wide; color reddish brown.

Frons broadly convex; surface shining, reticulate above, with rather sparse, indefinite, small and large punctures; vestiture of sparse, fine, moderately long hair.

Pronotum 0.94 times as long as wide; widest slightly behind middle, sides rather strongly arcuate, broadly rounded in front; anterior margin armed by eight (rarely 6-10) rather coarse serrations; summit broad, slightly behind middle; anterior slope coarsely asperate; posterior areas smooth, shining, almost impunctate, occasional minute, very shallow punctures evident. Vestiture of sparse hair on asperate area and lateral margins; a tuft of fine hair at median basal margin, its long axis transverse.

Elytra 1.0 times as long as wide, 1.1 times as long as pronotum; sides subparallel, very feebly arcuate on basal three-fourths, very broadly rounded behind; disc occupying about one-third of elytral length; striae not at all impressed, punctures small, shallow; interstriae smooth shining, at least eight times as wide as striae, minutely, sparsely, uniseriately granulate; punctures in lateral areas obscure to absent. Declivity rather steep, broadly convex; acutely margined from apex to interstriae 7, strial and interstrial punctures distinctly larger, granules evidently smaller. Vestiture of rows of fine, short, strial hair, and rows of much longer interstrial hair; longer and more conspicuous on declivity.

Male.- Not represented in material at hand.

Distribution.- Veracruz to Brazil; Micronesia and Australia to Sri Lanka (Ceylon).

USA: Intercepted at ports of entry, but not known to be established at Arizona (Nogales), California (San Francisco), New Jersey (Bound Brook), or New York (New York). Breeding populations occur in the following areas. MEXICO: Chiapas: Palenque Ruins. Veracruz: Coatzocoalcos, Matías Romero. HONDURAS: Zamorano. COSTA RICA: Dominical. Finca Gromaco on Río

Coto Brus, and Rincón de Osa (Puntarenas), Pandora (Limon), Playón, Santa Ana, San Ignacio de Acosta, and San José (San José). PANAMA: Barro Colorado Island, Ft. Clayton, and Garun Dam (Canal Zone), El Hato del Volcán (Chiriquí). OTHER AMERICAN COUNTRIES: Brazil, Colombia, Venezuela.

Hosts.- Hundreds of hosts have been reported.

Biology.- Unthrifty, broken, or cut branches about $1-3 \mathrm{~cm}$ in diameter are usually selected for attack. However, in Indonesia this species was responsible for primary attacks on tea, coffee, and other crops. The habits are as described for the genus. Males are exceedingly rare.

Notes. - The holotype of morigerus and the lectotype of luzonicus were examined. The above treatment was based on 176 other specimens. Hundreds of additional specimens were seen in the field in suitable habitats from Veracruz to Venezuela in addition to those reported above. It occurs in the most remote jungle areas as well as in agricultural communities. The date and place of introduction into America are not known. The earliest records known to me were from Colombia and dated 1958.

## 2. Xylosandrus crassiusculus (Motschulsky), n. comb.

 Fig. 181Phloeotrogns crassiusculus Motschulsky, 1866, Moskov. Obshch. Isp. Prirody, Otd. Biol. Biul. (Bull. Soc. Imp. Nat. Moscou) 39:403 (3 syntypes, female; India occidental, published as "Des Montagnes de Nura-Ellia," presumably the mountains near Nuwara Eliya, Ceylon; Zoological Institute, Academy of Ścience, Moscow, USSR)
Xyleborus scmiopacus Eichhoff, 1878, Mém. Soc. Roy. Sci. Liége (2)8:334 (Syntypes?, female; Nipon insula Japonica; presumably lost with Hamburg Mus.); Wood, 1969, Greal Basin Nat. 29:119. Synonymy
Xyleborus semigranosus Blandford, 1896, Trans. Ent. Soc. London 1896:211 (Holotype, female; Sumatra; British Mus. Nat. Hist.); Schedl. 1959. Trans. Roy. Ent. Soc. London 111:496. Synonymy Dryocoetes bengalensis Stebbing, 1908, Indian For. Mem., Zool. 1(1):I2 (Syntypes?, female; Goalpara, Assam, India; not located); Beeson, 1915, Indian For. 41:297. Synonymy
Xylcborus mascareuus Hagedorn, 1908, Deutsche Ent. Zeitschr. 1908:379 (Syntypes, females; Mauritius, and Bomole et Amani in Deutsch-Ostafrika; most lost with Hamburg Mus., one in Schedl Coll., others in H. E. Andrews Coll.?); Eggers, 1923, Zool. Meded. Leiden 7:130. Synonymy

Xyleborus okoumeensis Schedl, 1935, Stylops 4:271 (Syntypes, female; Carlshafen, Hessen-Nassau, Germany; Schedl Coll.); Schedl, 1959, Trans. Roy. Ent. Soc. London 111:496. Synonymy
Xyleborus declicigranulatus Schedl, 1936, J. Fed. Malay St. Mus. 18:30 (Syntypes, female; Selangor, Malay Peninsula; British Mus. Nat. Hist. and Schedl Coll.); Schedl 1959, Trans. Roy. Ent. Soc. London 111:496. Synonymy
Diagnosis.- This species is distinguished by the obsolete declivital striae, by the dense, confused, minute, declivital granules, and by the dull elytral surface on the declivity.

Female.- Length 2.1-2.9 mm (male 1.6 $\mathrm{mm}), 2.1$ times as long as wide, color reddish brown.

Frons as in germanus (Blandford) except more strongly, more uniformly reticulate. Pronotum about as in germanus except disc smoother, punctures slightly more abundant and more sharply impressed; dried specimens with posterior margin in front of scutellum with what appears to be a small, transparent membrane (apparently dried secretions suspended by setae).

Elytra 1.15 times as long as wide, 1.15 times as long as pronotum; slightly stouter than germanus; dise occupying slightly less than basal half; striae not impressed, punctures small; interstriae about six times as wide as striae, punctures fine, confused. Declivity steep convex, dull; striae obsolete; rather densely covered by small, confused, uniformly distributed granules. Vestiture of fine hair with shorter strial and interstrial
setae mostly confused, and longer setae in indefinite interstrial rows.

Male.- Remotely resembling female, dwarfed, without pronotal asperities; elytra more gradually arched, transition from disc to declivity more gradual, features more poorly defined.

Distribution.- South Carolina, Hawaii, Africa, S Asia, etc.

U'SA: South Carolina: Magnolia Gardens, Charleston Co.. 5-1II-75, cherry, R. Morgan; Summerville, Dorchester Co., sweet gum.

Hosts. - It has been reported from dozens of host species in Africa and Asia.

Biology.- In Malaya (Browne 1961:104), this species may attack cut material from 1.5 cm in diameter to large logs. It has also been reported to attack newly transplanted seedlings near the root collar. The galleries resemble those of Xyleborus dispar (Fabricius).

Notes. - The above treatment was based on the syntypes of crassiusculus, on the holotype of semigranosus, on syntypes of bengalensis, and on more than 100 other specimens. Syntypes of mascarenus, okumeensis, and declivigramulatus were also examined.

As with several other species in this tribe, this species evidently exists as two or more races, distinguished only by size, that apparently breed true. Their significance is not known.

This species has not previously been treated in Xylosandrus; however, in the present classification it is not possible to key it to

Fig. 181. Xylosandrus crassiusculus: 1, dorsal aspect of female; 2, galleries. (After Anderson 1974:864.)

Xyleborus, where it is usually treated. This problem in placement emphasizes the necessity for a thorough worldwide revision of the Xyleborini to redefine genera and to establish phyletic relationships. An abundance of usable characters have never been utilized in classifying this enormous group.

## 3. Xylosandrus germanus (Blandford)

Xylchorus germanus Blandford. 1894. Trans. Roy. Ent. Soc. London 1894:106 (Syntypes; Japan; British Mus. Nat. Hist.)
Xylosandrus germanus: Hoffman, 1941, J. Econ. Ent. 34:38
Diagnosis.- This species is distinguished from other American species of the genus by the larger size, by the absence of strial setae, and by the feebly impressed declivital striae.

Female.- Length 2.0-2.3 mm (male $1.5-1.7 \mathrm{~mm}$ ), 2.3 times as long as wide; color very dark brown.

Frons and pronotum essentially as in morigerus except pronotum 1.0 times as long as wide; pronotum with posterior areas commonly with some obscure, longitudinal, minutely etched lines and a few additional fine punctures; vestiture on pronotal disc of fine, rather short, sparse hair almost uniformly distributed.

Elytra 1.3 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal three-fourths, rather broadly rounded behind; striae not impressed, punctures small, shallow, distinct; interstriae smooth, shining, punctures replaced by minute, uniseriate, rather widely spaced granules. Declivity commencing very slightly behind middle, rather steep, broadly convex; subapical ventrolateral margin acutely elevated from apex to interstriae 7; striae usually very feebly impressed, punctures deeper than on disc. Vestiture of moderately long, rather sparse, interstrial hair at least on declivity; strial hair entirely obsolete.

Male.- Not represented in material at hand.

Distribution.- Illinois and Connecticut to West Virginia; Japan, Taiwan, Korea, China, Vietnam.

USA: Connecticut: New Canaan, Yalesville. Illinois: Alexander Co. Indiana: Jefferson Co. Kentucky: Leslie Co., Noble. New Jersey: Bloomfield, East Orange, Essex Co., Millburn, New Brunswick, Norwood, Rachwood, West Caldwell. New York: Kingston, New Rochelle, Oyster Bay, Suffolk Co. Ohio: Burlington. Chillicothe,

Clinton Co., Delaware Co., Tuscarawas Co. Pennsylvania: Delaware Co., Morristown. West Virginia: Chesapeake, Morgantown.

Hosts.- Acer sp., Carya sp., Cornus florida, Fagus sylvatica, Fraxinus sp., Juglans sp., Myrica, Liriodendron tulipifera, Pinus sp., Prunus sp., Pyrus sp., Quercus spp., Ulmus sp., Vitis sp.

Biology.- This species usually infests unthrifty, cut, or broken branches, boles, and stumps of a wide variety of hosts (Hoffman 1941). The female parental tunnels extend to a depth of about 1 cm in the wood, where they may branch into three or more arms. In each branch tunnel, the longitudinal, tabular, brood tunnels are developed as typical for this genus. Normally the females attack in May and produce up to 140 eggs each over a three-week period. Apparent overlapping generations continue to produce brood until September.

Notes.- The above treatment was based on 126 specimens from the United States and 4 from Japan. The types were examined but were not compared directly to my material.

## 4. Xylosandrus compactus (Eichhoff)

Xylchorus compactus Eichhoff, 1875, Ann. Ent. Soc. Belg. 18:201 (Syntypes, female; Japan; one syntype in Schedl Coll.)
Xylosandrus compactus: Nunberg, 1959. Beitr. Ent. 9:434.
Xiylchorus morstatti Hagedorn, 1912, Ent. Blätt. 8:37 Syntypes, female; Amani, Deutsch-Ostafrica, now Tanganyika; presumably lost with Hamburg Mus.); Murayama and Kalshoven, 1962, Ent. Bericht. 22:247-250. Synonymy
Diagnosis.- This species is distinguished from zimmermanni (Hopkins) by the darker color, by the slightly larger, more slender form, by the uniformly arched elytra from the middle of the elytral disc ta the apex, and by the transversely oriented tuft of hair at the base of the pronotum.

Female. - Length $1.4-1.7 \mathrm{~mm}$ (male $1.0-1.1 \mathrm{~mm}$ ), 2.1 times as long as wide; color very dark brown to almost black.
Frons and pronotum as in morigerus except punctures in posterior areas very slightly more numerous, more distinct.

Elytra 1.2 times as long as wide; disc occupying posterior half of elytra weakly arched; striae not impressed, punctures small, distinct, rather shallow; interstriae smooth, shining, four times as wide as striae, punc-
tures small, uniseriate, not at all granulate. Declivity evenly arched; sculpture as on dise except interstrial punctures finely granulate; posterolateral margin acutely elevated from apex to interstriae 7 . Vestiture of rows of fine, short, strial hair, and rows of longer, slender, pointed, interstrial hair; slightly longer on declivity.

Male.- Dwarfed, convex, somewhat similar to female but all characters poorly formed; anterior slope of pronotum flattened to feebly concave, weakly asperate.

Distribution.- Louisiana to Alabama and Florida, Brazil, Hawaii to Sri Lanka (Ceylon), Africa.
USA: Alabama: Several localities. Florida: Coconut Grove, 27-IV-44. Jacobina, C. A. Bass; Ft. Lauderdale, $7-$ VI-4I, Avocado, W. D. Wolfenbarger; Key Largo, 25-VI-51, Ichthyomethia communis, Vitis, Ardesia paniculata, Ficus, Cajanus cajon: Miami, I2-IX-43, mahogany, J. G. Curtis; West Palm Beach, 27-I-61. Louisiana: New Orleans. Mississippi: Biloxi, 20-VIII-68, Azalea, M. M. Price. OTHER AREAS: Brazil, Cuba. Itawaii to Sri Lanka (Ceylon), Africa.

Hosts. - Hundreds of trees and shrub species have been recorded.

Biology.- This species, known as the black twig borer, most commonly attacks healthy, vigorous twigs of living trees and shrubs. It is of primary economic importance in horticultural and ornamental plants. The adult females bore into twigs about 3 mm in diameter or larger and form a small cavity in the pith. The larvae feed mostly on the ambrosial fungus, but they also extend the pith tumel slightly. Under favorable circumstances the life cycle may be completed in less than a month.

Notes. - The above treatment was based on 106 Florida specimens and on 67 other specimens. The identity of this species was based on the material of Eggers and Schedl.

## 5. Xylosandrus zimmermanni (Hopkins)

Anisandrus zimmermanni Hopkins, 1915, U.S. Dept. Agric. Rept. 99:68 (Holotype, female: Biscayne, Florida; U.S. Nat. Mus., 7420)
Xylosandrus zimmermanni: Wood, 1962, Great Basin Nat. 22:79
Diagnosis.- This species is distinguished from compactus (Eichhoff) by the slightly stouter body form, by the more abruptly arched elytra, and by the longitudinally oriented median tuft of hair at the base of the pronotum. It is almost identical to curtulus
(Eichhoff) except as noted in the diagnosis of that species.

Female.- Length 1.3-1.5 mm (male $0.9-1.1 \mathrm{~mm}), 2.0$ times as long as wide; color dark brown to almost black.

Frons and pronotum as in morigerus, except anterior margin of pronotum more narrowly rounded, armed by four to six serrations; posterior areas reticulate, subshining, punctures sometimes more distinct; tuft of hair at base confined to median line, extending from basal margin about one-half distance to summit.

Elytra 1.1 times as long as wide; disc extending to middle of elytra; striae not impressed, punctures small, shallow, distinct; interstriae smooth, shining, four to six times as wide as striae, punctures minute, shallow, uniseriate. Declivity steep, broadly convex, more strongly arched near base; sculpture about as on disc except strial punctures slightly larger; posterolateral margin acutely elevated from apex to interstriae 7. Vestiture of rows of fine, short, strial hair and rows of moderately long, fine, pointed, interstrial hair.

Male- Essentially as in male compactus except anterior margin of pronotum more narrowly rounded, subserrate; anterior slope of pronotum feebly convex, more coarsely asperate in lateral areas; pronotal dise reticulate.

Distribution.-S Florida and Chiapas to Venezuela.
USA: Florida: Sebring. 20-VI-5I, Ardesia, Acer ruhrum, S. L. Wood MEXICO: Chiapas: Palenque Ruins. 22-VI-69, D. E. Bright. GUatemala: Volcán de Agua, 19-V-6t, 1000 mb , tree twig, S. L. Wood; Palin, Esquintla. 19-V-64, No. 588, Anonillo, S. L. Wood. COSTA RICA: Santa Ana, San José, 1-VIII-63, No. 92, Cupania guatemalensis. S. L. Wood; San Ignacio de Acosta, 5-VII-63. 1600 mm , No. 38, tree twigs, S. L. Wood; Tapanti, Cartago, 17-Vill-63. 1300 m, No. 102, Calliandra confusa, S. L. Wood: Guapiles, Limon. 22-VIII-66, 100 m , No. 116, liana, S. L. Wood; Pandora, Limon, 23-VIII-63, 50 m , No. 147. twig of shrub, S. L. Wood. VENEZUELA: Rancho Grande, Pittier Nat. Pk., 9-IV-70, 1100 m. No. 431. Nectandra, S. L. Wood.

Hosts.- Acer rubrum, Ardesia sp., Calliandra confusa, Cupania guatemalensis, etc.

Biology.- Cut, broken, and unthrifty twigs and small branches are attacked by this species. The habits are essentially as in morigerus (Blandford).

Notes.- The above treatment was based on the holotype of zimmermanni and on 48 other specimens. This species is almost identical to curtulus (Eichhoff).
6. Xylosandrus curtulus (Eichhoff), n. comb.

Xyleborus curtulus Eichhoff, 1869, Berliner Ent. Zeitschr. I2:281 (Holotype, female; Brazil; Brussels Mus.)
Xyleborus curtuloides Eggers, 1941, Arb. Morph. Taxon. Ent. Berlin-Dahlem 8:102 (Holotype, female; Gourbeyre, Guadeloupe; Eggers Coll., apparently on loan to Schedl). New synonymy
Nyleborus biseriatus Schedl, 1963, Reichenbachia 1:226 (Holotype, female; Nova Teutonia, Santa Catarina, Brazil; Schedl Coll.); Wood, 1973, Great Ba$\sin$ Nat. 33:187. Synonymy
Diagnosis.- This species is distinguished from the almost identical zimmermanni (Hopkins) by the smooth, shining posterior areas of the pronotum, and by the shorter, stouter, blunt, interstrial setae on the declivity.

Female.- Length $1.3-1.5 \mathrm{~mm}$ (male 1.0 mm ), 2.0 times as long as wide; color dark brown to almost black.

Identical to zimmermanni except as noted in diagnosis; blunt interstrial setae on declivity equal in length to distance between interstrial rows of setae.

Male.-As in male zimmermanni except posterior areas of pronotum shining, and declivital interstrial setae shorter.

Distribution.- Nayarit and Veracruz to Brazil.

MEXICO: Colima: 2 miles ( 3 km ) W Armeria, 28-Vl$65,70 \mathrm{~m}$, No. I35, Phoradendron, S. L. Wood. Nayarit: 5 miles ( 8 km ) N Rosamorada, 28-VI-65, 100 m , No. 252 , tree branch, S. L. Wood; Laguna Santa María, 6-VIl-65, 1000 m , No. 195, liana, S. L. Wood. San Luis Potosí: El Salto, 19-V1-53, Ficus, S. L. Wood. Oaxaca: 12 miles ( 19 km) S Matías Romero, 24-VI-67, No. 93, Phoradendron. S. L. Wood. Veracruz: 16 miles ( 25 km ) S Tecolutla, $25-$ VI-53, S. L. Wood. GUATEMALA; Rodeo, Esquintla, 4-VI-64, 150 m , No. 673, liana, S. L. Wood. HONDURAS: Zamorano, Morazán, I8-IV-64, 700 m , No. 569 in Phoradendron robustissimum, No. 544 in Serjania, S. L. Wood. OTHER COUNTRIES: Colombia, Venezuela, Brazil.

Hosts.- Ficus sp., Phoradendron spp., Serjania sp., etc.

Biology.- As in zimmermanni.
Notes.- The above treatment was based on the holotype of curtulus, on a cotype of curtuloides, on my homotype of biseriatus, and on 39 other specimens.

Because of a series from Caicedonia, Valle de Cauca, Colombia, having the posterior
areas of the pronotum mostly reticulate and the declivital interstrial setae slightly longer than normal for this species, it was placed in synonymy (Wood 1966) with zimmermanni. However, since then several additional series have been taken indicating broadly overlapping distributions with no indications of intergradation except for that one series. Based on material now at hand, curtulus and zimmernanni are both recognized as valid species.

## Genus THEOBORUS Hopkins

Theoborus Hopkins, 19I5, U.S. Dept. Agric. Rept. 99:57 (Type-species: Theoborus theobromae Hopkins, original designation.)
Diagnosis.- This genus has two separate sutures on the anterior face of the antennal club, both of which are continued on the posterior face as in Dryocoetoides Hopkins. It is distinguished from Dryocoetoides by the flat, smooth posterior face of the protibia, and by the somewhat smaller, more finely faceted eyes.

Description.- Length of females 1.7-2.9 $\mathrm{mm}, 2.3-2.8$ times as long as wide; males dwarfed, deformed, flightless.

Characters essentially as in Dryocoetoides except as noted in the above diagnosis.

Distribution.- Neotropical and perhaps elsewhere; the exact limits of the genus have not been defined.

Biology.- Not recorded, evidently similar to Dryocoetoides.

Notes.- Because of the exceedingly large number of tropical species of Xyleborini known largely from inadequate and inaccessible type series, a thorough revision of the generic classification of the tribe is impossible at the present time. Apparently characters are available that will serve to subdivide this enormous group into recognizable taxa. Although the present inadequate effort to accomplish this leaves much to be desired, it may stimulate others to recognize the problem and to contribute toward its solution.

Key to the Species of Theoborus

1. Elytral declivity strongly convex, its posterolateral margin rounded and devoid of crenulations; striae and interstrial punctures on disc small, shallow,

# confused, in definite rows on declivity; declivital interstrial punctures replaced by minute granules; vestiture of fine, abundant, long hair on disc and declivity <br> 2 

- Elytral declivity very broadly convex to weakly impressed, its posterolateral margin subacutely elevated and carinate or crenulate from sutural apex to interstriae 7 ; strial punctures in definite rows easily distinguishable from interstrial punctures3

2(1). Smaller; punctures on pronotal disc smaller, shallow; elytral punctures larger, more distinctly granulate on declivity; Costa Rica to Colombia and Venezuela; $1.8-2.1 \mathrm{~mm}$ 1. theobromae Hopkins

- Larger; punctures on pronotal disc larger, deeper; elytral punctures smaller, about half as large, very feebly granulate on declivity; Guatemala to Bolivia and Brazil; 2.3 mm 2. villosulus (Blandford)

3(2). Elytral declivity broadly convex, its posterolateral margin unevenly, somewhat crenulate; interstriae four to six times as wide as striae, strial punctures very small, usually little if any larger than those of interstriae (except molestulus); color dark brown4

- Elytral declivity moderately impressed at least on interstriae 2, its posterolateral margin a continuous costa; interstriae about three times as wide as striae, strial punctures moderately large, at least twice as large as those of interstriae; color yellowish to light reddish brown8
4(3). Body more slender, at least 2.6 times as long as wide ..... 5
Body stouter, less than 2.3 times as long as wide ..... 7

5(4). Declivital interstriae 2 impressed, unarmed on lower two-thirds, 1 and 3 slightly elevated, tubercles on 1 confused; Panama; 2.3 mm

- Declivital interstriae 1 to 3 uniseriately tuberculate, 2 not impressed, 1 and 3 not elevated

6(4). Strial punctures very small, spaced within a row by three to four diameters of a puncture; declivity rather abrupt, steep, its surface somewhat shagreened, cusps on ventrolateral margin higher, those near suture coarse, declivital interstrial vestiture of long, fine hair two to three times as long as distance between rows, strial hair up to half as long; Costa Rica to Panama; 1.7-2.0 mm
4. pristis Wood

- Strial punctures somewhat larger, spaced within a row by one to two diameters of a puncture; declivity more gradually, more broadly arched, shining, cusps on ventrolateral margin low, not particularly larger near suture; interstrial declivital vestiture stout, very slightly longer than distance between rows, strial hair fine, at least half as long as that of interstriae; Costa Rica; $1.8-2.0 \mathrm{~mm}$ 5. micarius Wood
$7(4)$. Interstrial punctures on disc confused, not granulate; declivital vestiture more abundant, consisting of strial rows and confused interstrial hair; Panama to Venezuela; 1.9-2.3 mm

6. crinitulus (Wood)

- Interstrial punctures uniseriate, replaced by small tubercles to base; elytral setae in uniseriate rows; Panama; 2.0-2.2 mm

7. molestulus Wood

8(3). Smaller; elytral declivity shorter, steeper, occupying 30 percent of elytral length, more narrowly impressed particularly on lower half; interstrial setae on declivity very stout, short, as long as distance between rows or less; Veracruz to Brazil; 2.3-2.5 mm
8. solitariceps Schedl

- Larger; elytral declivity more gradual, occupying 40 percent of elytral length, more broadly impressed on lower half; interstrial setae on declivity slender, pointed, about one and one-half times as long as distance between rows; Costa Rica to Colombia and Brazil; 2.5-2.9 mm

9. coartatus Sampson

## 1. Theoborus theobromae Hopkins

Theoborus theobromae Hopkins, 1915, U.S. Dept. Agric. Rept. 99:57 (Holotype, female; Dominicana, West lndies: U.S. Nat. Mus., 76.37 )
Xyleborus pseudococcotrypes Eggers. 1941. Arb. Morph. Taxon. Ent. Berlin - Dahlem 8: 105 (Holotype, female: St. Jean du Maroni, French Guina: Paris Mus.); Wood, 1962, Great Basin Nat. 22:79. Synonymy.
Xyleborus hirtellus SchedI, 1949, Rev. Brasil Biol. 9:271 (Syntypes, females; St. Vincent Island, British West Indies, and Trinidad; British Mus. Nat. His. and Schedl Coll.); Schedl, 1952, Ent. Blätt. 47-48:163. Synonymy
Diagnosis.- This small, stout, pubescent species has the elytral declivity rather strongly convex, with its ventrolateral margin broadly rounded and unarmed. It is closely allied to cillosulus (Blandford).

Female.- Length $1.8-2.1 \mathrm{~mm}, 2.2$ times as long as wide; color dark brown to almost black.

Frons broadly convex; surface reticulate, a few small granules below upper level of eyes; vestiture inconspicuous.

Pronotum 1.0 times as long as wide; sides moderately arcuate and not converging on basal two-thirds, rather broadly rounded in front; anterior margin armed by six to ten rather coarse serrations; summit broad, at or slightly behind middle; anterior slope coarsely asperate; posterior area reticulate, finely, shallowly, rather sparsely punctured. Vestiture of rather abundant, fine, moderately long hair.

Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; sides almost straight and parallel on slightly less than basal two-thirds, rather broadly rounded behind; striae not impressed, punctures small, shallow, in rows; interstriae smooth, shining, about six times as wide as striae, punctures confused, of same size and appearance as those of striae and not easily distinguished from them. Declivity convex, steep, occupying posterior half of elytral length; strial punctures indistinctly deeper, interstrial punctures uniseriate, each accompanied by a small granule; posterolateral margin rather broadly rounded, its
granules not distinctly larger elsewhere. Vestiture of fine, rather long, abundant hair, more conspicuous on declivity.

Male.- Dwarfed ( 1.2 mm ), flightless, and deformed; essentially as female but with characters less perfectly formed, except pronotum as in male Dryococtoides.

Distribution.- Veracruz and British West Indies to Colombia and Venezuela.

MEXICO: Chiapas: Palenque Ruins. Veracruz: Dos Amates. COSTA RICA: Rincón de Osa, Puntarenas, 11-VIII-66, 30 m, No. 55 , Ochroma, S. L. Wood; Dominical, Puntarenas, 9-XIl-63, 3 m , No. 298, tree branch, S. L. Wood; Turrialba, Cartago, 5-VII-63, 700 m, No. 20, Erythrina costaricensis, S. L. Wood; Guápiles, Limón. 22 -VIII-66, 100 m , No. 111, liana, S. L. Wood; Finca La Lola, 9-111-63. Theolroma cacao, J. L. Saunders. PANAMA: Barro Colorado 1sland, 27-XII-63, 70 m , No. 344 , liana, S. L. Wood; Ft. Clayton, 22-XII-63, 30 m , tree limb. S. L. Wood. OTHER COUNTRIES: Dominica, Barbados, Trinidad, Colombia, Venezuela.

Hosts.- Erythrina costaricensis, Ochroma sp., Theobroma cacao, etc.

Biology.- This species infests unthrifty, cut, or broken branches about $2-5 \mathrm{~cm}$ in diameter. The gallery system evidently is as in Dryocoetoides, but notes were not taken on a mature system.

Notes. - The above treatment was based on the holotype of thcobromae, on the "type" of hirtellus, and on about 300 other specimens. Evidently more than one specimen has been labeled as the type of hirtellus, as is a common feature of Schedl's species. The one in the British Museum (Natural History) is here considered to be the type.

## 2. Theoborus villosulus (Blandford)

Xyleborus villosulus Blandford, 1898, Biol. Centr. Amer., Coleopt. 4(6):204 (Holotype, female; Rio Naranjo, San Marcos, Guatemala; British Mus. Nat. Hist.)
Xyleborus coccotrypoides Eggers, 1943, Mitt. Münchner Ent. Ges. 33:388 (Holotype, female: Cochabamba, Bolivia; Paris Mus.); Wood, 1976, Great Basin Nat. 36:349. Synonymy
Xyleborus cillosus Schedl, 1949, Rev. Brasil Biol. 9:270 (Syntypes, female; Nova Teutonia, Brazil; Schedl and Plaumann Colls.); Wood, 1976, Great Basin Nat. 36:349. Synonymy

Diagnosis.- This species is distinguished from theobromae Hopkins by the larger size, by the coarser punctures on the pronotal disc, and by the finer punctures on the elytra.

Female.- Length $2.3 \mathrm{~mm}, 2.3$ times as long as wide; color brown.

As in theobromae except punctures on pronotal dise slightly larger and deeper; elytral punctures about half as large as those of theobromae, punctures appearing very feebly granulate on declivity.

Distribution.- Guatemala to Brazil and Bolivia.

GUATEMALA: Río Naranjo, San Marcos, C. C. Champion; Palín, Esquintlid, 19-V-65, 300 m, No, 585 , Anonillo, S. L. Wood. OTHER COUNTRIES: Bolivia, Brazil, French Guiana, and Venezuela.

Notes.- The above treatment was based on the holotypes of cillosulus, coccotrypoides, and villosus and on 10 other specimens.

## 3. Theoborus incultus (Wood)

Xyleborus incultus Wood, 1975, Great Basin Nat. 35:400 (Holotype, female; Ft. Clayton, Canal Zone, Panama; Wood Coll.)
Diagnosis.- This species is distinguished from pristis Wood by the larger size, by the more distinctly impressed strial punctures, and by the declivital sculpture as described below.

Female.- Length $2.3 \mathrm{~mm}, 2.6$ times as long as wide; color dark brown.

Frons and pronotum essentially as in micarius Wood except anterior margin of pronotum weakly produced at median line and armed by two larger serrations, punctures on posterior areas larger, at least twice as large as in micarius.

Elytra 1.5 times as long as wide, 1.3 times as long as pronotum; sides almost straight and parallel on basal 60 percent, narrowly rounded behind, a slight emargination at suture; striae not impressed, punctures small, distinctly impressed, spaced within a row by one to two diameters of a puncture; interstriae almost smooth, punctures fine, less than half as large as those of striae, moderately confused on basal third of disc, uniseriate behind. Declivity rather steep, convex; surface minutely granular on lower two-thirds, dull; interstriae 1 moderately elevated to near apex, armed by 15 or more small, pointed. confused denticles, 2 rather strongly impressed, armed on upper third by 4-6 similar,
uniseriate denticles, 3 slightly elevated, armed as in 1 except denticles almost uniseriate, 4-9 each with a row of fine denticles, 3 and 9 join and continue submarginally to apex as a moderately strong elevation, its crest armed by a row of about four denticles. Vestiture largely confined to sides and declivity; of fine, short strial and slightly longer interstrial hair, longest setae about equal in length to width of an interstriae.

Distribution.- Panama.
PANAMA: Ft. Clayton, Canal Zone, 22-XH-63, Cecropia branch, S. L. W'ood.

Notes.- The above treatment was based on the holotype.

## 4. Theoborus pristis Wood

Xyleborus (Theoborus) pristis Wood, 1972. Brigham Young Univ. Sci. Bull., Biol. Ser. 19(f):32 (Holotype, female; Tapanti. Cartago, Costa Rica; Wood Coll.)
Diagnosis.- The antennal club of this species is clearly as in theobromae Hopkins, but the relationship is not close. It differs from theobromae by the more slender form, by the less strongly serrate anterior margin of the pronotum, by the more broadly convex elytral declivity, and by the different sculpture of the elytral declivity.

Female.- Length $1.7-2.0 \mathrm{~mm}, 2.6$ times as long as wide; color very dark brown.

Frons broadly convex, a weak, narrow, transverse impression just above epistoma; surface strongly reticulate, punctures sparse, obscure, coarse; vestiture of sparse, fine, inconspicuous, long hair.

Pronotum 1.04 times as long as wide; essentially as in theobromae except surface more strongly reticulate, including anterior area between asperities, and anterior margin weakly serrate. Vestiture of fine, rather short hair on sides and asperate area, disc almost glabrous.

Elytra 1.3 times as long as wide; sides almost straight and parallel on basal threefourths, rather narrowly rounded behind, serrate near weakly, narrowly emarginate suture; striae not impressed, punctures minute, shallow, distinct, spaced within a row by three to four diameters of a puncture; interstriae smooth, shining, about eight times as wide as striae, punctures uniseriate, almost indistinguishable from those of striae.

Declivity confined to posterior fourth, steep, broadly convex; striae 1 weakly, others feebly impressed, punctures slightly larger, deeper and much closer than on disc; interstriae with punctures closer and uniseriately granulate, granules often obsolete near apex; suture narrowly emarginate, margin with a row of two to four coarse cusps near suture, this row continued along margin as four to eight somewhat smaller granules, margin rather narrowly rounded to interstriae 8. Vestiture confined to sides and declivity; on declivity consisting of rows of fine hair; strial hair short; interstrial hair two to two and one-half times as long as distance between rows.

Male.- Length (1.5-1.8 mm); essentially as in female, but with characters more poorly formed; pronotum 1.4 times as long as wide and essentially as in male theobromae.

Distribution.- Costa Rica and Panama.
costa rica: 6 km S San Vito, Puntarenas, 19-21-III-67, dead tree; Volcán, Puntarenas, 11-XII-63, 1000 m , No. 305 in huarumo, No. 308 in tree limb; S. L. Wood; Tapantí, Cartago, 17-IX-63, 1300 m , No. 184, Miconia caudata, S. L. Wood. PANAMA: Cerro Campana, 26-VII-66, 1000 m , tree branch, S. L. Wood.

Hosts.- Miconia caudata, etc.
Biology.- Tunnels were constructed in limbs and saplings $10-15 \mathrm{~cm}$ in diameter in rather hard wood. Mature gallery systems were not observed.

Notes. - The above treatment was based on the type series of 62 specimens.

## 5. Theoborus micarius Wood

Xyleborus (Theoborus) micarius Wood, 1972, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):33 (Holotype, female; Guápiles, Limón, Costa Rica; Wood Coll.)
Diagnosis.- This species is closely related to pristis Wood, but it is distinguished by the slightly larger, more closely spaced strial punctures, by the more gradual, more broadly arched elytral declivity, by the smaller cusps near the suture on the ventrolateral margin of the declivity, and by the very stout, short, declivital setae.

Female.- Length $1.8-2.0 \mathrm{~mm}, 2.7$ times as long as wide; color very dark brown.

Frons and pronotum as in pristis except pronotum outline somewhat more subquadrate and 1.1 times as long as wide.

Elytra 1.5 times as long as wide; outline essentially as in pristis; disc as in pristis except
strial punctures slightly larger, spaced within a row by two to three times diameter of a puncture; interstriae about five to six times as wide as striae, punctures uniseriate, distinctly smaller than those of striae. Declivity occupying 50 percent of elytral length, more gradual and more broadly convex than in pristis; sculpture as in pristis except posterolateral margin subacute, its summit rather weakly crenulate from weak sutural emargination to interstriae 7 . Vestiture of rows of strial and interstrial setae, finer and shorter on disc; declivital strial hair very fine and short, interstrial setae coarse, blunt, each about one to one and one-half times as long as distance between rows.

Distribution.- Costa Rica.
COSTA RICA: Tapantí, Cartago, 17-IX-63, 1300 m , No. 182, tree branch, S. L. Wood; Guápiles, Limón, 22-VII-66, 100 m , No. 120, Cordia, S. L. Wood.

Host. - Cordia sp.
Biology.- Specimens were attacking branches $5-7 \mathrm{~cm}$ in diameter.

Notes.- The above treatment was based on the type series of 12 specimens.

## 6. Theoborus crinitulus (Wood)

Xyleborus crinitulus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):34 (Holotype, female; 46 km SE Socopo, Barinas, Venezuela; Wood Coll.)
Diagnosis.- This species is distinguished from micarius Wood by the larger size, by the more closely, more deeply punctured pronotal disc, by the confused discal interstrial punctures, and by the steeper elytral declivity that has different sculpture.

Female.- Length $1.9-2.3 \mathrm{~mm}, 2.3$ times as long as wide; color rather dark reddish brown.

Frons as in micarius except with moderately numerous, small, rounded graanules. Pronotum as in micarius except serrations on anterior margin larger and punctures on disc more numerous and deeper.

Elytra 1.3 times as long as wide, 1.2 times as long as pronotum; striae not impressed, punctures small, rather shallow, spaced within a row by one or two times diameter of a puncture; interstriae four to five times as wide as striae, shining, with irregular lines, punctures fine, moderately deep, confused on basal two-thirds, uniseriate toward declivity.

Declivity steep, broadly convex, occupying 42 percent of elytral length; strial punctures almost twice as large as on disc; interstriae uniseriately tuberculate, tubercles rather widely spaced, pointed, moderately fine except rather coarse on lower half of 1 ; suture slightly produced just before apex; subapical posterolateral margin acutely, subcrenulately elevated from suture to interstriae 8. Vestiture hairlike, rather abundant, of variable length, mostly rather short.

Distribution. - Panama and Venezuela.
PANAMA: Barro Colorado Island, Canal Zone, 27-XII-6:3, 70 m , No. 345, tree branch, S. L. Wood; Ft. Clayton, Canal Zone, 22-XII-63, 30 m , No. 317, tree branch, S. L. Wood. OTHER COUNTRIES: Venezuela.

Notes. - The above treatment was based on the type series of 21 specimens.

## 7. Theoborus molestulus Wood

Xyleborus (Theoborus) molestulus Wood, 1975, Great Basin Nat. 35:400 (Holotype, female; Barro Colorado Island, Canal Zone, Panama; Wood Coll.)
Diagnosis.- This species is distinguished from crinitulus Wood by the interstrial granules on the disc, by the uniseriate rows of elytral setae, and by other characters.

Female. - Length $2.0-2.2 \mathrm{~mm}, 2.2$ times as long as wide; color dark brown.

Frons as in crinitulus except less strongly reticulate, more sparsely punctured.

Pronotum about as in crinitulus except anterior margin armed by eight serrations, posterior areas very finely, shallowly punctured.

Elytra 1.2 times as long as wide, 1.3 times as long as pronotum; sides almost straight and parallel on basal two-thirds, broadly rounded behind; striae not impressed, punctures rather small, shallow, distinct, spaced by one to two diameters of a puncture; interstriae almost smooth, three times as wide as striae, each with a uniseriate row of fine tubercles from base to apex. Declivity occupying posterior half of elytral length, moderately steep, broadly convex; sculpture as on disc except striae 1 feebly impressed; posterolateral margin acutely, subcrenulately elevated from apex to interstriae 7. Vestiture of interstrial rows of long, erect hair from base to apex, alternate setae twice as long as distance between rows, alternating with setae half that length on disc and declivity.

Distribution.- Panama.

PANAMA: Barro Colorado Island, Canal Zone, 27-XII-63, No. 348, tree branch: Ft. Clayton, Canal Zone, 22-XII-63, 30 m , No. 363, tree branch; Madden Forest, Canal Zone, 2-I-64, 70 m . No. 365, tree seedling; 13 km S El Hato del Volcán, Chiriquí, 7-1-64, tree seedling; all taken by me.

Notes.- The above treatment was based on the type series of 15 specimens.

## 8. Theoborus solitariceps Schedl

Xyleborus solitariceps Schedl. 1954, Dusenia 5:45 (Lectotype, female; Rondon, Paraná, Brazil; Sched! Coll., designated by Schedl 1979, Kataloge wiss. Sam. Nat. Mus. Wien 3(2):232)
Diagnosis.- This species is distinguished from the very closely related coartatus (Sampson) by the smaller size, by the shorter, steeper elytral declivity, by the more narrowly impressed declivity, and by the much stouter declivital setae.

Female.- Length 2.3-2.5 mm, 2.5 times as long as wide; color yellowish to reddish brown.

Frons as in theobromae (Hopkins) except more shining and with rather abundant, small, rounded granules on lower third. Pronotum 1.04 times as long as wide; essentially as in theobromae except punctures rather coarse, shallow, rather sparse; surface slightly more shining; glabrous in discal area.

Elytra 1.4 times as long as wide; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; disc occupying basal 70 percent of elytral length; striae not impressed, punctures moderately coarse, rather shallow; interstriae about three times as wide as striae, smooth, shining, punctures uniseriate, about half as large as those of striae. Declivity steep, shallowly, rather broadly impressed; sutural interstriae slightly elevated, striae 1 and interstriae 2 rather strongly impressed; interstriae 3 moderately elevated except near its apex; strial punctures about as on disc; subapical ventrolateral margin acutely costate from suture to interstriae 7. Vestiture of rows of fine, short, strial hair, and rows of erect, interstrial setae, those on disc rather fine, those on declivity very coarse, short, each about equal in length to distance between rows.

## Distribution.- Veracruz to Brazil.

MEXICO: Veracruz: Rancho Tepetates, 21-III-80, S$043,50 \mathrm{~m}, \mathrm{~T} . \mathrm{H}$. Atkinson. HONDURAS: Zamorano, Morazán, 18-IV-64, 700 m . No. 565, Dioclea megacarpa,
S. L. Wood; La Lima, Cortéz, 5-V-64, 200 m , No. 573, Suietenia, S. 1. Wood. COSTA RICA: Playa del Coco. 18-X-63, 8 m , No. 231, Citrus, S. L. Wood; Dominical, Puntarenas, 24-1X-64, Theobroma cacao, J. L. Saunders; Guápiles, Limón, 22-VIII-66, 100 m , No. 122 in Inga, No. 119 in Terminalia, S. L. Wood; Finca La Lola, Limón, 4-111-63, Theobroma cacao, J. L. Saunders. OTHER COUNTRIES: Colombia, Venezuela, Brazil.

Hosts.- Citrus aurantifolia, Dioclea megacarpa, Swietenia sp., Terminalia sp., and Theobroma cacao.

Biology.- This species was taken from dying branches $3-7 \mathrm{~cm}$ in diameter.

Notes. - The above treatment was based on Schedl's syntype and on 22 other specimens.

## 9. Theoborus coartatus Sampson

Cyleborus coartatus Sampson, 1921, Amn. Mag. Nat. Hist. (9)7:32 (Holotype, female; Trinidad; British Mus. Nat. Hist.)
Cyleborus artecuneolus Schedl, 1939, Proc. Roy. Ent. Soc. London 8:14 (Holotype, female; Trinidad; British Mus. Nat. Hist.); Wood. 1966, Great Basin Nat. 26:31. Synonymy
Diagnosis. - This species is distinguished from the closely related solitariceps Schedl by the larger size, by the longer, more gradual declivity, by the more broadly impressed declivity, and by the longer, more slender declivital setae.

Female.- Length $2.5-2.9 \mathrm{~mm}, 2.4$ times as long as wide; color yellowish to reddish brown.

Frons and pronotum as in solitariceps.
Elytra as in solitariceps except dise occupying only 60 percent of elytral length; interstriae 2 usually with punctures confused; lower half of declivity more broadly impressed; declivital interstrial setae finer, longer, pointed, each one and one-half to two times as long as distance between rows.

Distribution.- Costa Rica to Brazil.
COSTA RICA: Río Damitas, Dota Mts., San José, 18-11-64, 250 m . No. 431, Theobroma, S. L. Wood; Turrialla, Cartago, $5-$ VIl- $63,700 \mathrm{~m}$, No. 22, tree branch, S . L. Wood: Cuápiles, Limón, 22-V111-66, 100 m , No. 102. tree bole, S. L. Wood; Pandora, Limón, 23-V11I-63, 50 m, No. 145, Mimosa, S. L. Wood; Finca La Lola, 4-II163, Theobromu cacao, J. L. Saunders. PANAMA: 13 km S El Hato del Volcán, Chiriquí, $7-1-64,1000 \mathrm{~m}$, tree sapling, S. L. W'ood. OTHER COUNTRIES: Colombia, Brazil.

Hosts.- Mimosa sp., Theobroma cacao, T. sp., etc.

Biology.- Specimens were taken from the bole of small trees $8-20 \mathrm{~cm}$ in diameter.

Notes.- The above treatment was based on the holotypes of coartatus and artecuneolus and on 26 other specimens, 3 of which were compared directly to both holotypes.

## Genus XYLEbORUS Eichhoff

Phloeotrogus Motschulsky, 1863, Bull. Soc. Imp. Nat. Moscou 36(1):512 (Type-species: Phloeotrogus obliquecaudata Motschulsky, subsequent designation by Hopkins, 1914, Proc. U.S. Nat. Mus. 48:127); Wood, 1974, Bull. Zool. Nomencl. 31:230. Appeal for suppression pending.
Xyleborus Eichhoff, 1864, Berliner Ent. Zeitschr. 8:37 (Type-species: Bostrichus monographus Fabricius, subsequent designation by Lacordaire, 1866, Histoire Naturelle des lnsects. Genera des Coleopteres 7:381)
Anisandrus Ferrari. 1867, Die Forst- und Baumzuchtschälichen Borkenkäfer, p. 24 (Typespecies: A pate dispar Fabricius, monobasic)
Anaerctus Dugès, 1888, Ann. Soc. Ent. Belge 31:140 (Type-species: Anaeretus guanajuatensis Dugès, monobasic)
Progenius Blandford, 1896, Ann. Soc. Ent. France 65:20 (Type-species: Progenius fleutiauxi Blandford, subsequent designation by Hopkins, 1914, Proc. U.S. Nat. Mus. 48:128)

Mesoscolytus Broun, 1904, Ann. Mag. Nat. Hist. (7)14:125 (Type-species: Apate inurbanus Brom, monobasic)
Cyclorhipidion Hagedorn, 1912, Dentsche Ent. Zeitschr. 1912:355 (Type-species: Cyclorhipidion pelliculosum Hagedorn $=$ Xyleborus perlactus Schedl, monobasic)
Heteroborips Reitter, 1913, Wiener Ent. Zeit. 32(Beiheft):79, 82 (Type-species: Bostrichus cryptographus Ratzeburg, monobasic)
Xyleborips Reitter, 1913, Wiener Ent. Zeit. 32(Beiheft):111 (Type-species: Xyleborus meuseli Reitter, monobasic)
Coptoborus Ilopkins, 1915, U.S. Dept. Agric. Rept. 99:53 (Type-species: Coptoborus emarginatus Hopkins $=$ Xyleborus vespatorius Schedl, original designation)
Eumallacea Hopkins, 1915, U.S. Dept. Agrie. Rept. 99:54 (Type-species: Xyleborus wallacei Blandford, original designation)
Ambrosiodmus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:55 (Type-species: Xijleborus tachygraphus Zimmermann, original designation)
Terminalinus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:57 (Type-species: Terminalinus terminaliae Hopkins, original designation)
Boroxylon Hopkins, 1915, U.S. Dept. Agric. Rept. 99:58 (Type-species: Boroxylon stephegynis Hopkins $=$ Phloeotrogus bidentatus Motschulsky, original designation)
Cryptoxyleborus Schedl, 1937, Sarawak Mus. J. 4:550 (Type-species: Cryptoxyleborus naecus Schedl, subsequent designation by Schedl. 1962, Rev. Ent. Noçambique 5:103)

Streptocranus Schedl, 1939, Tijdschr. Ent. 82:52 (Typespecies: Streptocranus mirabilis Schedl. monobasic)
Diagnosis.- This exceedingly large and complex genus requires considerably more taxonomic attention than is given here. The diagnosis and description presented here apply only to American forms, which include only a minor part of the subgenera occurring throughout the world. In this restricted treatment Xyleborus includes those American Xyleborini having the antennal club obliquely truncate, with not more than one suture at the extreme apex of the posterior face; the anterior coxae are contiguous, or if narrowly separated the intercoxal piece is deeply notched, the scutellum is moderately large and flat, it attains the general surface level of the elytral bases, and it completely fills the sutural notch at the elytral bases.

Description.- Length $1.6-5.9 \mathrm{~mm}$, 1.9-3.4 times as long as wide; color yellowish brown to black. Sexual dimorphism extreme; males exceedingly rare, flightless.

Female frons convex, variously covered by punctures and granules; vestiture sparse, inconspicuous. Eye oval; shallowly to deeply emarginate. Antennal scape elongate; funicle 5-segmented; club obliquely truncate, not more than one suture may show at extreme apex on posterior face. Pronotum variously sculptured. Scutellum moderately large, flat, flush with surface of elytral bases, completely filling sutural notch. Elytra variously sculptured. Anterior coxae contiguous, if apparently narrowly separated, then intercoxal piece conspicuously notched on its longitudinal axis. Tibiae as characterized for tribe.

Distribution.- Worldwide, wherever woody plants grow; about 1,500 nominate species exist; however, perhaps as many as a third of them have been or should be placed in synonymy; about 73 species occur in North and Central America.

Biologx.- Virtually all parts of almost any woody plant may be attacked by representatives of this genus. Some species attack apparently healthy tissue, some prefer comparatively old, sour $\log s$, but most species prefer recently cut, injured, or unthrifty material. All species culture an ambrosial fungus on the walls of their tunnels. The rare males
are flightless; only the female seeks a new host and establishes a new tunnel. Tunnels may be of the cave type or of a simple or highly complex branching system; in certain species groups it is not uncommon for several females to use the same original entrance tunnel. The larvae are reared in the parental galleries and usually participate in the enlargement of the gallery system. If mating occurs, it takes place in the brood chambers and usually is between siblings or mother and son.

In those species that have been studied (Entwistle 1964, Norris and Chu 1970) the males are haploid and females are diploid. An unmated female evidently produces only male offspring, with which she then mates in order to produce female offspring. Because of this extreme inbreeding and partial parthenogenesis, any mutant female is the potential founder of a new morphological race or species.

Notes. - The extremely large size and complexity of this genus, coupled with the difficulty of determining exactly what a species is, due to arrhenotokous parthenogenesis, has produced taxonomic chaos. The following attempt to subdivide the group into subgenera and species groups that reflect phylogeny is based on the examination of more than 600 named species from all parts of the world. Many inadequacies in this classification are readily apparent, but perhaps it will provide a small step toward a more satisfactory treatment of the entire genus.

In the above, tentative generic synonymy citations of authors establishing synonymy were omitted because there is some hesitation about the validity of the synonymy in some instances and in others names are here retained as subgenera. Several generic names treated as synonyms of Nyleborus by Schedl were omitted because they are oriental in distribution and they are being treated differently in a preliminary unpublished manuscript by another author. Certain synonymy can be established, however, including: Xylebortus ( = Anaeretus, Anisandrus, and possibly Cyclorhipidion), Ambrosiodmus (= Phlocotrogus, suppressed), Progenius ( = Boroxylon), Coptoborus ( $=$ Streptocramus and possibly part of Cryptoryleborus). These groups,
together with Heteroborips (not known to me), Euwallacea, and Terminalinus, apparently form recognizable genera.
Xyleborus signatus Schedl (1949:278) was named from Mexico; however, the type is an erroneously labeled specimen of nepos Eggers that does not belong to the American fauna (Wood 1975:23). Similarly, the unique type of vitiosus Schedl (1940:367) appears to be an erroneously labeled specimen of adelographus Eichhoff from Brazil (Wood 1975:22). Xyleborus linearis Schedl (1949:273) is an erroneously labeled
specimen of the European dryographus Ratzeburg (Wood 1977:211). These names should be dropped from the Mexican fauna.
(Note added in press.) A detailed study of major groups within the Xyleborini was commenced after the present manuscript was completed. Although that study incorporates radical changes in generic assignments for almost half of the species here placed in Xyleborus, it is not sufficiently advanced that changes can be made here, except for the recognition of Theoborus. A preview of coming changes is presented in Wood (1980:96).

## Key to Females of the Species of Xyleborus

1. Anterior coxae narrowly separated, usually a small notch or depression between anterior and enlarged posterior portions of intercoxal piece; body stout, less than 2.0 times as long as wide; elytral declivity variously excavated, commencing at or anterior to middle of elytra and variously ornamented by spines on interstriae 3; pronotum wider than long, rather narrowly rounded in front and armed by a series of teeth

- Anterior coxae contiguous (intercoxal piece deeply notched if continuous); body more slender, at least 2.2 times as long as wide; declivity and pronotum variable

2(1). Elytral declivity deeply, rather broadly sulcate from base to apex, lateral margins equally, rather strongly elevated throughout, their summits armed by a series of three to eight coarse denticles of subequal size3

- Lower half of declivity much more broadly, shallowly excavated than upper or basal half, its lateral margins much less strongly elevated than on basal half, margins armed on upper half by a pair of coarse submammiform or spinose prominences, a series of smaller denticles variously distributed above and below these major prominences4

3(2). Declivital face densely, very minutely punctured, with strial punctures shallow, moderately coarse, close, spaced by less than diameter of a puncture; Guatemala and Panama to Colombia and Venezuela; 2.3-2.8 mm

1. perebeae (Ferrari)

- Declivital face devoid of interstrial punctures, smooth, shagreened to shining, strial punctures small, obscure, spaced by more than diameter of a puncture; Costa Rica to Panama; $3.2-3.6 \mathrm{~mm}$

2. salvini Blandford

4(2). Declivity commencing behind middle of elytra, steep, ventrolateral margin on lower half distinctly elevated, subacutely angulate; declivital face closely, deeply covered by confused punctures; surface irregular; major spine on declivity stout, pointed, a coarse, pitlike impression just below its apex on posteromedian side; Costa Rica to Panama; 2.7-3.0 mm
3. pandulus Wood

[^13]5(4). Major spines on elytral declivity stout, about one-third declivital length from upper margin, its apex blunt ..... 6- Major spine at or slightly below middle of declivity, comparatively slender, itsapex sharply pointed7

6(5). Larger; largest tooth anterior to major declivital spine closer to major spine than to suture; excavated area above major spine distinctly narrower than area immediately posterior to major spine; major spine much larger; Costa Rica to Panama; 3.8-4.3 mm
4. godmani Blandford

- Smaller; largest tooth anterior to major declivital spine closer to suture than to major spine; excavated area of declivity anterior to major spine distinctly wider than excavated area immediately posterior to major spine; Veracruz to Panama; 3.3-3.9 mm (two subspecies)

5. sharpi Blandford

7(5). Prothorax light reddish brown, elytra black in mature specimens; surface of declivital excavation dull, very densely, deeply punctured by minute points, strial punctures rather obscure; Pacific slope of Costa Rica and Panama; 3.5-3.8 mm
6. sanguinicollis Blandford

- Prothorax and elytra black in mature specimens; declivital surface smooth, shining, devoid of impressed points, strial punctures small, clearly impressed; Atlantic slope of Costa Rica and Colombia; 3.7-3.9 mm

8(1). Anterior margin of pronotum procurved and armed by several rather coarse serrations; posterolateral margin of elytral declivity usually rounded, frequently armed by tubercles or spines, if subacutely costate then costa extending from suture to interstriae 3-5 (except only to 7 in couplets 12-13); strial setae usually present9

- Anterior margin of pronotum straight or procurved, unarmed by serrations (except subserrate in spathipennis, fornicatus); posterolateral margin of elytral declivity rounded or costate, costa never dentate, when present, extending from suture to interstriae 7; strial setae almost never present (for exceptions see couplet 35)22
9(8). Stouter species; pronotum 1.0-1.1 times as long as wide; elytra with sides sub- parallel on at least basal two-thirds, declivity more broadly convex to excavated ..... 10
- $\quad$ Slender species; pronotum 1.2-1.3 times as long as wide; elytra rather strongly tapered on posterior half, declivity gradual, convex or narrowly excavated; subgenus Coptoborus ..... 17
10(9). Larger, 2.3-4.0 mm; interstrial punctures strongly confused; posterolateral margin of declivity subacutely elevated, almost devoid of denticles ..... 11
- Smaller, $1.7-2.9 \mathrm{~mm}$; interstrial punctures uniseriate; posterolateral margin of declivity more broadly rounded, armed by a series of denticles or spines, inter- striae 1 either unarmed or with a row of small granules; declivital punctures either in rows or very small and shallow; subgenus Neoxyleborus ..... 15
11(10). Elytral declivity convex, striae distinct and in definite rows, interstriae 1 with minute granules equal in size to those of other interstriae ..... 12
- Declivity rather strongly impressed; declivital punctures rather large, close, distinct, strongly confused, sutural interstriae armed by two to four stout denticles ..... 14

12(11). Subapical posterolateral declivital costa armed by three to five distinct denticles; interstrial punctures at base of dise and punctures on pronotal disc averaging slightly larger; Minnesota and Quebec to West Virginia; 2.8-3.5 mm $\qquad$

- Subapical posterolateral declivital costa of uniform height, undulating but unarmed by denticles; interstrial and pronotal punctures averaging distinctly smaller 13

13(12). Anterior margin of pronotum armed by six to eight subequal serrations; strial punctures on declivity larger, deeper, interstriae there one and one-half times as wide as striae; British Columbia and Nova Scotia to Utah and Virginia; $2.8-3.5 \mathrm{~mm}$
9. dispar (Fabricius)

- Anterior margin of pronotum armed by two to six serrations, median pair always conspicuously larger; declivital strial punctures smaller, less strongly impressed, declivital interstriae at least twice as wide as striae; Ontario and Quebec to Missouri and Georgia; 2.3-2.6 mm

10. sayi (Hopkins)

14(11). Predeclivital impression beginning at or posterior to middle of elytra; elytral pubescence abundant, particularly on declivity; denticles on declivital interstriae 3 averaging larger; $S$ Texas to Guatemala; 3.8-4.2 mm
11. horridus Eichhoff

- Predeclivital impression beginning on basal fourth of elytra; elytral pubescence rather sparse, less abundant on declivity than on dise; denticles on declivital interstriae 3 averaging smaller; Costa Rica to Colombia; 3.4-4.0 mm

15(10). Declivity steeper, moderately flattened, occupying posterior 30 percent of elytral length; declivital interstriae 1 armed by a row of minute, pointed granules; declivital vestiture of rather slender bristles; Nayarit to Colima; 1.8-2.1 mm ....
13. palatus Wood

- Declivity more gradual, rather strongly excavated, occupying at least 40 percent of elytral length; declivital interstriae 1 unarmed except for one or two small denticles at base; declivital vestiture of slender to very stout scales 16

16(15). Punctures on elytral declivity very small, strongly confused, each bearing a short, broad scale, striae obsolete, face of declivity broadly concave, devoid of spines, a few small denticles on basal and lateral areas; Chiapas to Brazil; $1.7-2.3 \mathrm{~mm}$
14. squamulatus Eichhoff

- Strial punctures on elytral declivity in rows; declivital vestiture of rather slender scales; margins of declivity armed by two or more pairs of large spines 17

17(16). Largest spine on elytral declivity less than twice as long as its basal width, about equal in length to width of one discal interstriae; declivity less strongly excavated, armed by two to five pairs of spines (variable), although two pairs usually predominate, and several smaller denticles; Jalisco to Brazil, Hawaii; $1.8-2.6 \mathrm{~mm}$
15. spinulosus Blandford

- Largest declivital spine at least two and one-half times as long as its basal width, about equal in length to distance from suture to discal striae 3; declivity more strongly excavated, always armed by two pairs of major spines and several minor denticles; Costa Rica to Colombia; 2.4-2.9 mm .... 16. ferox Blandford
17(9). Elytral declivity concavely excavated, interstriae 3 armed by about two to five denticles, posterolateral margin strongly elevated toward apex and emarginate at suture; Veracruz to Argentina; $2.3-2.8 \mathrm{~mm}$

[^14]18(17). Declivital interstriae 2 feebly impressed; elytral apex not acuminately produced, not distinctly emarginate at suture, posterolateral margin not elevated along interstriae 9; declivital interstriae 1-7 with fine denticles except 2 usually unarmed; Panama to Brazil; 1.6-1.7 mm
18. catulus Blandford

- Elytral apex more narrowly produced and suturally emarginate; declivital 19

19(18). Elytral apex obtusely subacuminate, sutural emargination shallow; small tubercles on declivital interstriae 1 more widely spaced, an average distance of two or more diameters of a strial puncture between tubercles; granules on declivital interstriae 2 average smaller in size than on 1 or 320

- Elytral apex acutely acuminate, sutural emargination deeper than wide; granules, if present, on declivital interstriae 1 spaced by distance equal to diameter of one strial puncture
20(19). Elytral declivity slightly more gradual; granules on posterolateral margin of declivity poorly formed, very small; largest tubercles on interstriae 1 and 3 small, subequal in size; interstrial setae on declivity moderately long, stout, almost scalelike; San Luis Potosí and Veracru : to Brazil; 1.8-2.2 mm

19. pseudotenuis Schedl

- Elytral declivity slightly steeper; two or three tubercles on posterolateral margin of elytral declivity coarse, almost as large as those on interstriae 1 ; tubercles on declivital interstriae 1 conspicucusly larger than those on 3 ; interstrial setae on declivity moderately long, rather slender; Panama to Peru; $1.6-1.7 \mathrm{~mm}$

20. cuneatus Eichhoff

21(19). Apex of elytra not at all crenulate or serrate; all elytral interstriae entirely devoid of granules and tubercles; Costa Rica; 1.9 mm
21. exutus Wood

- Apex of elytra ending in a conspicuous cusp, lateral margin with about four additional serrations; declivital interstriae 1-7 uniseriately, very finely granulate; Costa Rica to Brazil; $1.8-2.2 \mathrm{~mm}$

22. tolimanus Eggers

22(8). Pronotum subcircular to subquadrate, its posterior half asperate, asperities almost as coarse as those on anterior slope (except scalaris); subgenus Ambrosiodmus

- Posterior half of pronotum smooth, rarely minutely granulate, reticulate or not
23(22). Antennal club larger, with two sutures on posterior face; pronotal summit at or slightly in front of middle, anterior slope steeper; elytral declivity slightly impressed, interstriae 2 either unarmed or granules smaller than on 1 or 3; smaller species24
- Antennal club smaller, with not more than one suture on posterior face; pronotal summit behind middle, arched from base, anterior slope less abrupt; elytral declivity impressed or not, interstriae 2 with tubercles as large or larger than those on 1 or 3 ; larger species
24(23). Larger; interstriae 1 on declivity feebly elevated, usually as high as 3,2 feebly sulcate, its granules as large as those on 1; discal interstriae about three to four times as wide as striae, punctures often granulate; color reddish brown to black; Mississippi and Virginia to Florida and Brazil; $2.0-2.4 \mathrm{~mm}$

23. obliquus (LeConte)

- Smaller; interstriae 1 on declivity not elevated, declivital granules absent; elytral punctures larger, deeper, discal interstriae twice as wide as striae; color very dark brown; Florida, Puerto Rico; 1.8-2.1 mm

24. devexulus Wood
25(24). Elytral declivity evenly convex, all interstriae equally granulate ..... 26

- Elytral declivity weakly to rather strongly impressed toward suture, interstriae 1 unarmed or bearing very small granules, 2 rather strongly granulate or dentate ..... 29
26(25). Posterior areas of pronotum weakly granulate; pronotum distinctly longer than wide; interstrial punctures on disc confused, not at all granulate; Costa Rica; $4.0-4.3 \mathrm{~mm}$ 26. scalaris Schedl
- Posterior areas of pronotum asperate; pronotum wider than long; interstrial punctures weakly confused to uniseriate, finely granulate ..... 27
27(26). Discal interstrial punctures fine, shallow, interstriae three to four times as wide as striae; declivity shallowly bisulcate, punctures fine, fine granules on basal half only; El Salvador; Quercus; 2.7 mm ..... 25. devexus Schedl
- Discal interstrial punctures rather coarse, deep, interstriae two to four times as wide as striae; declivital punctures larger, granules larger and more generally distributed ..... 28
28(27). Declivital striae 1 not impressed; strial punctures on declivity only slightly larger than on disc; declivital interstriae three times as wide as striae; Puebla to Chiapas; $3.3-3.5 \mathrm{~mm}$ 27. rusticus Wood
- Declivital striae 1 slightly impressed; strial punctures on declivity almost twiceas large as on disc; declivital interstriae one and one-half times as wide asstriae; Connecticut to Virginia; $2.4-2.6 \mathrm{~mm}$28. rubricollis Eichhoff
$29(25)$. Sutural area of declivity feebly impressed, armed by at least a few very fine granules; discal interstriae only slightly wider than striae, strial punctures coarse, deep; declivital striae 2 wider than 1 and 3 combined, its granules coarse, much larger than those on 1 or 3; Florida; 2.4 mm 29. opimus Wood
- $\quad$ Sutural area of declivity moderately to rather strongly impressed, interstriae 1 unarmed, 2 rather coarsely granulate or dentate ..... 30
30(29). Strial punctures on disc coarse, deep, interstriae less than one and one-half times as wide as striae; declivity near suture rather strongly impressed, inter- striae 2 armed by two or three coarse tubercles, strial punctures very coarse; Florida and Louisiana to Puerto Rico; 2.5-3.0 mm ................... 30. lecontei Hopkins)
- Strial punctures on dise rather small, very shallow, interstriae more than two and one-half times as wide as striae ..... 31
$31(30)$. Smaller; elytral declivity rather strongly impressed toward suture; punctures on declivital striae small, three or more times as wide as sutural interstriae; color reddish brown; Oaxaca and Veracruz to Brazil; 2.4-2.8 mm

31. guatemalensis (Hopkins)

- Larger; declivity rather shallowly impressed toward suture; punctures on de- clivital striae coarse, about twice as wide as sutural interstriae; color dark reddish brown to black ..... 32
32(31). Smaller; elytral punctures and minor granules finer; Illinois and Pennsylvania to Alabama and Georgia; $3.4-3.8 \mathrm{~mm}$ 32. tachygraphus Zimmermann
- Larger; elytral punctures and minor granules coarser; Guatemala; 4.9 mm

33. rugicollis Blandford
33a(22). Posterior face of antennal club with a subapical suture on apical third; Asian species introduced into North America ..... 33b

- Posterior face of antennal club without sutures, apical margin usually formed by acute margin of basal corneous area; endemic species ..... 33c

| 33b(a). | Smaller, stouter; elytra 1.2 times as long as wide; pronotum more nearly sub- <br> circular, anterior margin strongly procurved, coarsely serrate; declivity more |
| :--- | :--- |
| gradual but more strongly convex; Panama, Hawaii, S Asia, Africa, etc.; |  |
| polyphagous; 1.9-2.3 mm .................................................... 34a. fornicatus Eichhoff |  |

- Larger, more slender; elytra 1.5 times as long as wide; pronotum subquadrate, anterior margin weakly procurved, serrations weak to absent; declivity steeper, rather weakly convex; New York to Pennsylvania, N Japan; polyphagous; $3.4-3.8 \mathrm{~mm}$

34b. validus Eichhoff
$33 \mathrm{c}(\mathbf{a})$. Larger, stouter species; pronotum usually less than 1.1 times as long as wide, subquadrate; elytral declivity more gradual, occupying at least 40 percent of elytral length, its armature of fine granules usually on all interstriae; subgenus Euwallacea, in part

- Mostly smaller, slender species, at least 3.0 times as long as wide; pronotum at least 1.1 times as long as wide, its sides almost straight and parallel on basal two-thirds, its anterior margin always strongly procurved; elytral declivity steeper, usually confined to less than posterior 30 percent of elytral length, its interstriae often unequally armed by small to moderately coarse, often unequal tubercles
34(33). Anterior margin of pronotum serrate; declivital tubercles equally developed on all interstriae; body 2.2 times as long as wide; elytra 1.5 times as long as pronotum; Nicaragua and British Guiana to Bolivia and Brazil; 4.4-5.3 mm

34c. spathipennis Eichhoff

- Anterior margin of pronotum unarmed; declivital tubercles on interstriae 1 and 3 distinctly larger, those on other interstriae minute to obsolete; body 2.5 times as long as wide; elytra 1.8 times as long as pronotum; Nicaragua to Ecuador; $5.1-5.9 \mathrm{~mm}$ 35. princeps Blandford

35(33). Pronotum subquadrate or if anterior margin strongly procurved then pronotum less than 1.15 times as long as wide; interstriae $1-3$ similarly sculptured or 2 with tubercles; elytral declivity more gradual, usually occupying at least 50 percent of elytral length, usually more broadly convex, with posterolateral margin more conspicuous; small strial setae commonly present in addition to those of interstriae; mostly larger, stouter species, dark brown to black36

- Pronotum never subquadrate, at least 1.2 times as long as wide, its sides usually
almost straight and parallel on posterior half; declivital interstriae 1 (usually)
and 3 armed by tubercles, 2 unarmed (except titubanter); declivity steeper, oc
cupying less than posterior 35 percent of elytral length; strial setae absent (ex
cept in sparsipilosus and some volvulus); mostly smaller, slender species,
yellowish or reddish brown (except for a few rare black species)

36(35). Pronotum quadrate; elytral declivity usually steeper, more broadly rounded
behind; sides of elytra usually subparallel on at least basal two-thirds

- Pronotum strongly procurved on anterior margin; declivity usually more grad
ual, often beginning well in front of middle of elytra; sides of elytra usually
tapered from middle, more narrowly rounded behind ..... 51

37(36). Striae on posterior two-thirds of elytra deeply impressed, interstriae of this area convex, shagreened (dull), and each with a row of moderately coarse, rounded granules to apex; posterolateral margin of declivity subacutely elevated from apex to interstriae 7; Costa Rica to Colombia and French Guiana; $2.7-2.8 \mathrm{~mm}$ 36. asper Eggers

- $\quad$ Striae equally impressed and interstriae devoid of granules on more than basal half of elytra ..... 38
38(37). Granules on elytral declivity more widely spaced, usually conspicuously irregular in size and spacing, spaced by distances much greater than diameter of an adjacent strial puncture (if size irregular, ignore smallest granules for this measurement)
- Granules on declivity of uniform size, uniformly spaced by distances not greater than diameter of an adjacent strial puncture; interstrial setae on declivity mostly very short
39(38). Larger species, larger than 3.0 mm ; granules on interstriae $1-3$ about equal in size and number
- Smaller than 2.5 mm ; granules on declivital face averaging distinctly smaller and usually less numerous on interstriae 2 than those on 1 and 3

40(39). Body stouter, less than 2.5 times as long as wide; elytra rather broadly,
obtusely rounded behind ..... 41

- Body more slender, more than 2.7 times as long as wide; elytra more narrowly, subacutely rounded behind ..... 43
41(40). Elytral declivity more strongly, more narrowly convex, posterolateral margin subacutely elevated, feebly concave between crest and interstriae 3; discal striae moderately to rather strongly impressed; Costa Rica to Brazil; 3.2-3.8 mm

37. caraibicus Eggers

- Elytral declivity very broadly convex, posterolateral margin more strongly, acutely elevated, concave from its crest to suture; discal striae very weakly impressed
42(41). Elytral declivity with transverse impression weak, obscure, suture convex on longitudinal axis on upper half, straight on lower half; posterolateral area of declivity very shallowly concave, Costa Rica to Panama; 3.7-4.0 mm $\qquad$

38. commixtus Blandford

- Elytral declivity rather strongly, transversely impressed on lower half, suture distinctly concave on longitudinal axis on lower half; posterolateral area of declivity rather strongly concave; Costa Rica; 4.0 mm

39. lacunatus Wood

43(40). Larger; declivital interstriae 1-3 bearing similar, small, variable granules, each interstriae with at least 15 granules; declivity more broadly convex; Costa Rica to Venezuela and French Guiana; 3.2-3.6 mm
40. politus Hagedorn

- $\quad$ Smaller; declivital interstriae 1 and 3 each armed by about 4 to 8 granules of variable size, 2 bearing one moderately coarse tubercle just below middle and a series of about 6 to 10 minute granules; declivity strongly convex; Panama to Venezuela; 3.1-3.3 mm

41. improvidus Schedl

44(39). Declivity more gradual, occupying posterior 40 percent of elytra; its surface shining; declivital interstrial bristles largely obsolete, longest setae about half as long as distance between rows; Costa Rica; 2.2-2.3 mm
42. dissimulatus Wood

- Declivity steep, occupying posterior fourth of elytral length, its surface usually dull; declivital interstrial hair up to twice as long as distance between rows; Veracruz to Panama and Brazil; 2.2-2.5 mm

43. posticus Eichhoff

45(38). Longitudinal axis of suture on lower half of declivity straight or feebly convex; posterolateral margin of declivity rather weakly elevated, area immediately above its crest slightly convex; more slender, body 2.8 times as long as wide

- Lower half of declivity transversely impressed, longitudinal axis at suture slightly to moderately concave; posterolateral margin of elytral declivity more strongly, subacutely elevated, area immediately above its crest flattened to shallowly concave; stouter, less than 2.6 times as long as wide

46(45). Smaller; declivital bristles usually less than half as long as distance between rows; Costa Rica to Venezuela; $2.5-2.7 \mathrm{~mm}$
44. concentus Wood

- Larger; declivital bristles as long as distance between rows; Panama; 3.6 mm .. 45. quadratus Blandford

47(46). Pronotum subshining, disc with distinctly impressed, sublongitudinal parallel lines (modified reticulation); posterior margin of elytra more narrowly rounded behind; declivital interstrial bristles mostly two-thirds as long as distance between rows; Costa Rica and French Guiana; 2.3-2.7 mm

- Pronotum almost smooth, weakly reticulate, shining; posterior margin of elytra much more broadly rounded behind; declivital interstrial bristles mostly less than one-third as long as distance between rows
48(47). Declivity steeper, interstrial granules variable, very minute granules interspersed among larger ones; transverse impression on lower half of declivity not as strong; Chiapas to Peru and British Guiana; 2.9-3.3 mm

47. discretus Eggers

- Declivity more gradual, interstrial granules of uniformly small size or obsolete; transverse impression on lower half of declivity stronger 49

49(47). Interstriae four to five times as wide as striae, strial punctures only slightly larger than those of interstriae; declivity shagreened, interstrial tubercles mostly obsolete, small, widely spaced on basal half; Costa Rica to Colombia; $3.4-4.0 \mathrm{~mm}$
48. schildi Schedl

- Interstriae less than three times as wide as striae, strial punctures about twice as large as those of interstriae; declivity shining, tubercles regularly, rather closely spaced to apex
50(49). Larger; strial punctures on disc and declivity distinctly larger, discal striae 2 distinctly sinuate; interstriae 2 and 3 on disc with punctures confused; punctures on pronotal disc larger; Costa Rica; 3.8 mm 49. tribulatus Wood
- Smaller; strial punctures slightly smaller, 2 straight on disc; interstriae 2 and 3 with punctures uniseriate; punctures on pronotal disc very fine; Costa Rica and Colombia to French Guiana; 2.3-2.6 mm 50. semipuıstatus Eggers

51(36). Strial punctures on disc confused but distinguishable from interstrial punctures, interstrial punctures confused and at least minutely granulate on their anterior margins; strial and interstrial punctures on declivity confused, indistinguishable; Costa Rica and French Guiana; 3.5-3.8 mm
51. tumucensis Hagedorn

- Strial punctures in rows on disc and declivity, easily distinguished from much smaller interstrial punctures 52

52(51). Declivity rather steep (see also titubanter); sides of elytra parallel on at least basal two-thirds, more broadly rounded behind; discal interstriae clearly punctured or granulate, sometimes confused on 3; declivital striae moderately confused or not; about two to four widely spaced, small denticles on each declivital interstriae
Declivity gradual, occupying about posterior half of elytral length; sides of
elytra parallel on basal half, tapered, then more narrowly rounded behind;
interstrial punctures largely obsolete on disc (except demissus) ............................... 54

53(52). Smaller; elytral declivity gradual, occupying posterior half of declivital length;
posterior areas of pronotum smooth, punctures sparse, minute; Costa Rica and
Colombia to French Guiana; $2.8-3.1 \mathrm{~mm}$

52. geayi Hagedorn

- Larger; elytral declivity rather steep, occupying posterior third of elytral length; posterior half of pronotum closely, shallowly punctured, their posterior margins minutely subgranulate; Costa Rica to Colombia; 4.2-4.4 mm

| 54(52). | Declivity commencing behind middle; interstriae punctured on disc; declivity <br> convex or rather strongly, transversely impressed just below middle; interstrial <br> granules on declivity slightly larger .............................................................................. 55 |
| :--- | :--- |
| - | Declivity more gradual, flattened to very shallowly, extensively concave; inter- <br> strial punctures on disc almost obsolete; interstrial granules on declivity fine to <br> obsolete .......................................................................................... 56 |

55(54). Declivity evenly, weakly arched both longitudinally and transversely; declivital interstrial setae very short, scalelike; Costa Rica; 2.0 mm
55. demissus Wood

- Declivity rather strongly, transversely impressed just below middle; declivital interstrial setae slender, almost hairlike; Costa Rica and Venezuela; 3.3-3.7 mm

54. vismiae Wood

56(54). Declivity commencing slightly behind middle, flattened to feebly convex on less than posterior fifth; declivital surface shining, rows of fine granules present on interstriae 1-3; Costa Rica; 2.8-3.4 mm (see also 56a. praestans Wood)

56b. meritus Wood

- Declivity commencing at or anterior to middle, flattened to feebly concave on more than posterior third; declivital surface shagreened (dull); larger species
57(56). Declivital interstriae 1-3 each armed by a row of small, widely spaced granules; declivity occupying posterior half of elytral length, more narrowly, less extensively flattened; Costa Rica to Panama; 4.0-4.4 mm

57. costaricensis Blandford

- Declivital interstriae 1 and 2 usually entirely devoid of granules (one or more occasionally present); declivity occupying posterior two-thirds of elytral length, shallowly concave or broadly, shallowly bisulcate; Costa Rica; 4.5-4.8 mm 58. prolatus Wood

58(35). Pronotal summit at or near middle, anterior slope of pronotum occupying distinctly more than anterior third; pronotum stouter, about 1.2 times as long as wide; discal interstriae punctured (punctures almost obsolete in titubanter); declivital striae clearly indicated (except in imbellis), punctures almost as on disc59

- Pronotal summit well in front of middle, anterior slope steep, confined to less than anterior third; pronotum at least 1.3 times as long as wide; discal interstriae devoid of punctures; declivital striae obsolete, declivital punctures confused, very much smaller than those on disc74

59(58). Declivity not as steep, occupying 33-38 percent of elytral length (except 25
percent in celsus), more broadly convex to flattened, its posterolateral margin
narrowly, subangulately rounded to subacutely elevated ..... 60

- Declivity steep, convex, occupying 25 percent of elytral length, except 38
percent in viduus), its posterolateral margins broadly, obtusely rounded

60(59). Elytra more narrowly rounded behind, declivity more gradual; approximately alternate interstrial punctures on disc finely granulate almost to base; approximately alternate interstrial bristles very coarse on disc and declivity; minute strial hair present on declivity61

- Elytra more broadly rounded behind, declivity usually steeper; punctures on discal interstriae never granulate, vestiture finer, usually shorter

61(60). Smaller; tubercles on declivital interstriae 3 small, little if any larger than those on 1; elytra rather narrowly rounded behind; posterolateral margin of elytra subacutely costate; Costa Rica and Panama to French Guiana; 2.2-2.4 mm
59. sparsipilosus Eggers

- Larger; tubercle near middle of declivity on interstriae 3 conspicuously larger; elytra subacuminate behind; posterolateral margin of elytra narrowly rounded; Costa Rica and Panama to French Guiana; 2.5-2.7 mm

60. productus Hagedorn

62(60). Declivital interstriae 2 with pointed granules extending to or slightly below middle, their size equal to those on 1 and 3 ; interstrial punctures on disc mostly obsolete or exceedingly small; mature color black; Puebla; 3.0-3.2 mm 61. titubanter Schedl

- Declivital interstriae 2 unarmed except for two or three small granules at base
in all but imbellis; interstrial punctures on disc distinct ............................................ 63

63(62). Strial punctures on disc small in semidefinite rows to moderately confused, interstrial punctures rather abundant, confused; declivital punctures small, deep, confused, straie not evident; elytral vestiture short, fine, abundant; declivity unarmed; Veracruz to El Salvador; 4.4-4.7 mm 62. imbellis Blandford

- Punctures on discal striae and interstriae in uniseriate rows; elytral declivity armed by several denticles

64(63). Declivity rather strongly flattened or uncommonly very shallowly impressed, interstriae 1 and 2 unarmed except at base, 3 armed by about three widely spaced denticles, the one near middle conspicuously larger than others; interstrial setae on disc and declivity of about equal diameter and length (some often broken); color reddish brown; Michigan and Massachusetts to Argentina, pantropical; $2.0-3.3 \mathrm{~mm}$

- Declivity distinctly convex, interstriae 1 armed by one to several small tubercles on lower two-thirds; short and long interstrial setae commonly alternate in a row on disc and declivity

65(64). Surface of elytral declivity shagreened (dull); declivity not as steep, more gently convex, denticles averaging slightly smaller; color yellowish to light reddish brown; Ohio and Massachusetts to Argentina, pantropical; 2.0-2.7 mm
64. affinis Eichhoff

- Surface of elytral declivity shining; declivity at least slightly steeper, convex, denticles averaging slightly larger

66(65). Declivity broadly, feebly convex, very steep, interstriae 1 broad, armed by two rather coarse, widely spaced denticles on its extreme lateral margin, 2 broad, flat, 3 armed by about three smaller denticles on its lateral margin, lateral margins moderately abrupt; Iowa and Vermont to E Texas and Florida; 3.6-4.5 mm

- Declivity more strongly convex, interstriae not usually broad, denticles on interstriae 1 smaller and not displaced laterally; lateral margins of declivity more broadly rounded; smaller than 3.0 mm (the following three forms are virtually identical and may intergrade)

$$
67
$$

67(66). Striae not at all impressed, strial punctures very small, spaced within a row by two or more diameters of a puncture; interstriae about three times as wide as striae, punctures small, regularly spaced by distances similar to those of striae; Florida and Baja California to Costa Rica .................. 66. volvulus (Fabricius) (s. str.)

- $\quad$ Striae feebly to distinctly impressed, strial punctures larger, spaced by average distances less than diameter of a puncture; interstriae less than twice as wide as striae, often weakly convex, punctures usually more irregularly spaced

68(67). Color reddish brown; anterior tibia armed by six or seven socketed teeth, basal one rather remote from others; parts of Mexico to South America; 2.1-2.8 mm 66. volvulus (Fabricius) (=torquatus Eichhoff)

- Color black; anterior tibia armed by seven socketed teeth, basal (seventh) tooth not noticeably more widely spaced than others; Michoacán and Guatemala to Costa Rica; 2.7-2.9 mm

67. morulus Blandford

69(59). Female pronotum slightly impressed, weakly sulcate on more than basal half, sulcus one-fourth as wide as pronotum at base, half as wide near middle, anterior slope without asperities, setae on median two-thirds of anterior half rather abundant, very short, recumbent, sometimes appearing almost scalelike; declivity either flat or strongly sulcate

- Basal half of female pronotum convex, anterior half asperate; declivity basically convex, interstriae 1 armed

70(69). Declivity somewhat flattened, its surface reticulate-granulate, interstriae 1 as high as 3, 1-3 each with a row of very fine granules; pronotal impression not as strong, lateral setae finer; Missouri to Pennsylvania; 2.3-2.4 mm

## 68. planicollis Zimmermann

- Declivity very strongly sulcate on median half, interstriae 3 much higher than 1, 1 and 2 smooth and shining and unarmed by granules, 3 armed by two coarse tubercles ( $0-4$ smaller tubercles sometimes present); pronotal impression stronger, lateral setae coarser; Missouri to Maryland and Florida; 2.0-2.5 mm ..

69. viduus Eichhoff

71(69). Elytral declivity broadly convex, somewhat flattened, its surface dull, minutely rugose-reticulate, denticles on interstriae 1 and 3 very small; color yellowish brown to light reddish brown; Minnesota and Maine to E Texas and Florida; $2.3-2.7 \mathrm{~mm}$
70. xylographus (Say)

- Declivity more narrowly convex, smooth, shining, some denticles on interstriae 1 and 3 larger, color rather light to dark reddish brown; in coniferous hosts (host of californicus unknown)

72(71). Elytral vestiture abundant, short, strial setae present; centers of strial punctures on declivity reticulate-granulate; interstrial punctures on disc confused; California; $2.0-2.2 \mathrm{~mm}$

- Elytral vestiture in interstrial rows; interiors of strial punctures on declivity smooth, shining

73(72). Discal striae with punctures distinctly larger, interstriae not more than one and one-half times as wide as striae; denticles on declivital interstriae 1 and 3 smaller, their basal widths and heights equal to less than diameter of a strial puncture; Ontario and New Jersey to E Texas and Florida; 2.3-2.7 mm $\qquad$ 72. pubescens Zimmermann

- Discal interstriae at least twice as wide as striae; some declivital tubercles with height and basal width greater than diameter of a strial puncture; British Columbia and New York to Honduras; 2.2-2.7 mm

73. intrusus Blandford

74(58). Larger; strial punctures on disc very small, shallow, interstriae about four times as wide as striae; declivity distinctly flattened on central half; Veracruz to Costa Rica; 4.0-4.4 mm
74. declivis Eichhoff

- Smaller; strial punctures larger, deeper, interstriae about twice as wide as striae; declivity feebly flattened on smaller central area; Veracruz to Panama, Venezuela; 2.9-3.3 mm 75. macer Blandford

## 1. Xyleborus perebeae (Ferrari) Fig. 182

Amphicranus (?) perebeae Ferrari. 1869, Berliner Ent. Zeitschr. 12:252-253 (Holotype, female; Colombia; not in Vienna Mus., apparently lost.)
Xylehorus perebeae: Blandford, 1895. Biol. Centr. Amer., Coleopt. 4(6):200
Diagnosis.- This species is distinguished from the very closely related flavipes (Fabricius) by the dense, very minute, deep, impressed points on the elytral declivity, by the less deeply excavated elytral declivity, with the denticles on the lateral margins averaging much smaller, and by the slightly smaller average size.

Female. - Length 2.3-2.8 mm, 2.0 times as long as wide; color black.

Frons broadly convex; surface reticulate, rather coarsely, obscurely, sparsely punctured; vestiture of sparse, fine, long, inconspicuous hair.

Pronotum 0.97 times as long as wide; sides, subparallel, weakly arcuate on basal half, rather narrowly rounded in front; anterior margin armed by six to eight small teeth, median denticles slightly larger; summit at middle, anterior slope steep, coarsely asperate; posterior areas reticulate, punctures minute, sparse.

Elytra 1.1 times as long as wide, 1.1 times as long as pronotum; sides almost straight and parallel on basal two-thirds, broadly, feebly emarginate behind, with declivital denticles projecting slightly; striae not impressed, punctures small, shallow, distinct; interstriae almost smooth, shining, about six times as
wide as striae, punctures very small, distinct, moderately confused. Declivity occupying posterior half of elytra, broadly, rather deeply excavated; entire face of excavated area minutely, densely punctured by impressed points, striae 2 and 3 clearly indicated, punctures slightly larger than on dise; sutural interstriae feebly elevated; lateral margins much higher than suture, ascending from striae 2 to moderately acute interstriae 3 ; interstriae 1 and 2 at base of elytra each with two or three moderately large, acutely pointed denticles, 3 with a row of about 9-12 sharply pointed denticles extending from declivital base to near apex, those in middle area moderately large, row usually interrupted just below middle; interstriae 4-7 with much smaller denticles. Vestiture of rows of fine, short, strial and interstrial hair on disc, much stouter on sides of declivital area; declivital face glabrous.

Male. - Similar to female except 2.3 mm , pronotal summit at base, anterior slope gradual, more broadly convex, more finely asperate, anterior margin unarmed, basal median margin transversely carinate and precipitous behind; elytra similar but less perfectly formed, declivital interstriae 2 with fine granules.

Distribution.- Guatemala to Panama and Colombia to Venezuela.
guatemala: Trece Aguas in Alta Verapaz. Costa RICA: Moravia and Turrialba in Cartago, Finca La Lola, Guápiles, and Pandora in Limón, Rincón de Osa in Puntarenas, Santa Ana, San Isidro del General, San Ignacio de Acosta, and Playón in San José. PANAMA: Barro Colorado Island, Ft. Clayton, and Madden Forest in
the Canal Zone, El Hato del Volcán in Chiriqui, and Cerro Campana in Cocle. OTHER COUNTRIES: Colombia, Venezuela.

Hosts.-Coffea robusta, Crotalaria sp., Ochroma sp., Psidium guava, Theobroma cacao, and numerous other woody plants.

Biology.- The female usually attacks cut or broken branches and tree seedlings 2-7 cm in diameter. The entrance tunnel extends directly into the wood to a depth of about 1 cm , then bifurcates and follows a growth ring both to the right and to the left, on the same transverse plane, and often meeting and joining on the opposite side of the branch. Masses of eggs are deposited in the tunnels. The larvae feed in congress upon the ambrosial fungus and, evidently, also upon the woody tissues, thus expanding the original gallery along the grain of the wood to form a large tabular chamber barely large enough to accommodate the mass of growing larvae. As many as $30-50$ larvae may be produced by one female. Males are rare. It is a common species in agricultural and other disturbed areas.

Notes.- The above treatment was based on 101 females and one male. The identity of this species was based on the series of Blandford, Eggers, and Schedl.

## 2. Xyleborus salvini Blandford

Xyleborus salvini Blandford, 1898, Biol. Centr. Amer., Coleopt. 4(6):200 (Lectotype, female; Volcán de Chiriquí, Panama; British Mus. Nat. Hist., present designation)
Diagnosis.- This species is distinguished from the very closely allied flavipes (Fabricius) by the more broadly, less deeply excavated elytral declivity, with denticles on the lateral margins smaller and stouter, by the larger strial punctures on the declivital face, and by the larger size.

Female.- Length $3.2-3.6 \mathrm{~mm}, 2.0$ times as long as wide; color black.

As in perebeae except frontal punctures slightly coarser; punctures on pronotal disc slightly larger; strial punctures smaller, interstriae about eight times as wide as striae; interstrial punctures on disc smaller, almost obsolete. Declivity as in perebeae except surface smooth, slightly shagreened, devoid of impressed points, strial punctures distinctly smaller, very shallow, spaced by two to four diameters of a puncture; denticles on basal and lateral margins averaging slightly smaller. Vestiture slightly longer than in perebeae.

Distribution.- Costa Rica to NW Panama.

Fig. 182. Xyleborus spp., female declivities with setae omitted: 1, perebeae, normal, 2, same, a variation; 3, sanguinicollis: 4, godmani; 5, pandulus; 6, ebenus.

COSTA RICA: Escasú. San José, 2-X-63, I300 m. No. 218, tree seedling, S. L. Wood: Tapanti, Cartago, 2-VII63, 1300 m , No. I0, Conostegia ocrstediana, S. L. Wood. PANAMA: Volcán de Chiriquí, G. C. Champion.

Hosts.- Conostegia oerstediana, etc.
Biology.-As in perebeae. It is an exceedingly rare species.

Notes.- The above treatment was based on the four syntypes and on two other females that were compared to the type. The first syntype is here designated as the lectotype of salvini Blandford.

## 3. Xyleborus pandulus Wood

Fig. 182
Xylehorus pandulus Wood. 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(I):34 (Holotype, female: Fort Clayton, Canal Zone, Panama; Wood Coll.)
Diagnosis.- This rather common species has been incorrectly identified by Schedl, and others, as carians (Fabricius). It differs from varians by the smaller average size, by the steeper elytral declivity, and by the flatter lower half of the declivity with its ventrolateral margin subacutely elevated and its face irregular and closely, coarsely punctured.

Female.- Length $2.7-3.0 \mathrm{~mm}, 2.0$ times as long as wide: color dark brown. almost black.

Frons and pronotum as in perebeae (Ferrari) except each minute puncture on pronotal disc with a minute, smooth, shining spot on its posterior margin.

Elytra 1.0 times as long as wide, 1.06 times as long as pronotum; disc limited to basal half; disc as in perebeae except strial punctures slightly smaller. Declivity abruptly impressed at base, steep, rather broadly, deeply excavated on upper half, lower half more broadly flattened and with its abrupt lateral margin weakly elevated; basal margin abrupt, armed by about 4-8 small, pointed denticles scattered from interstriae 1-3; margin at interstriae 3 bearing a large, stout, conical spine one-fourth declivital length from basal margin, a larger setiferous pore just below its apex; interstriae 4 with four to six small, pointed denticles on and just before declivital margin, 5 with similar denticles extending along margin to or near sutural apex: declivital face closely, deeply, rather coarsely punctured, surface subshining, somewhat irregular. Vestiture limited to stout, scalelike bristles on margin and sides of declivity.

Distribution.- Costa Rica to Panama.
COSTA RICA: Dominical, Puntarenas, 9-XII-63, 3 m , No. 30I, tree branch, S. L. Wood; Boston, Limón, IX-64, Theobroma cacao, J. L. Saunders; Finca La Lola, Limón, VIII-63. Theobroma cacao, J. L. Saunders. PANAMA: Canal Zone: Ft. Clayton, 22-XII-63, 30 m , No. 320, tree limb, S. L. Wood; Madden Forest, 2-I-64, 70 m, No. 367, tree limb, S. L. Wood: Limón Bay, 30-XII-63, 5 m , No. 354, tree branch, S. L. Wood.

Biology. - As in perebeae.
Notes.- The above treatment was based on the type series of 20 specimens.

## 4. Xyleborus godmani Blandford Fig. 182

Ňylchorus godmami Blandford, 1898, Biol. Centr. Amer., Coleopt. 4(6):197 (Holotype, female; Bugaba, Chiriquí, Panama: British Mus. Nat. Hist.)
Xylchorus caelebs Blandford, 1895, Biol. Centr. Amer. Coleopt. 4(6): I98 (Holotype, male; Volcán de Chiriqui, Panama; British Mus. Nat. Hist.); Wood, 1972, Great Basin Nat. 32:198. Synonymy
Diagnosis.- This species is distinguished from pandulus Wood by the larger size, by the narrower excavated area on the anterior part of the elytral declivity, and by the larger major spine on the elytral declivity, with a different arrangement of minor denticles.

Female. - Length 3.8-4.3 mm, 2.0 times as long as wide; color black.

Frons and pronotum about as in perebeae except punctures on pronotal disc slightly larger.

Elytra 1.1 times as long as wide, 1.2 times as long as pronotum; sides almost straight and parallel on basal half, very slightly narrowed then broadly rounded behind except broadly emarginate on median fourth; disc occupying basal 40 percent of elytra; striae minute, interstrial punctures minute, indistinct, surface slightly irregular. Declivity abrupt, rather gradual, broadly excavated; a very large, blunt spine on margin in line with interstriae 3 about one-fifth of declivital length from base; basal margin between major spine and suture armed by four or more very small denticles and one moderately large, pointed denticle located closer to major spine than to suture; lower half of ventrolateral margin below major spine subacutely rounded and armed by several small denticles, one or two at upper and lower ends slightly larger; declivital face smooth, obscurely shagreened, punctures very small, striae 1,2 , and 3 obscure, a few confused punctures on interstriae
2. Vestiture of stout bristles on margin and sides of declivity.

Male.- Obscurely resembling female; $3.3-4.2 \mathrm{~mm}$; pronotal summit at base, anterior slope gradual, somewhat flattened, punctured, asperities obsolete, basal margin transversely carinate; elytral declivity about as in female but more deeply excavated, major spine smaller, minor denticles reduced or absent, punctures on face of declivity distinctly larger.

Distribution.- Costa Rica to Panama on the Pacific slope.

COSTA RICA: Santa Ana, San José, 4-X-63, 1300 m , No. 223, tree limb, S. L. Wood; Río Damitas, Dota Mts., San José, 18-Il-64, No. 436, tree sapling, S. L. Wood: Dominical, Puntarenas, $9-\mathbb{N} 11-63,3 \mathrm{~m}$, No. 295, tree branch, S. L. Wood; Rincón de Osa, Puntarenas, I1-VIl66, 30 m , No. 69, Vismia, S. L. Wood. PANAMA: Volcán de Chiriqui, G. C. Champion; Bugaba, Chiriquí, G. C. Champion.

Hosts.- Vismia sp., etc.
Biology.- As in perebeae. It is a rare species.

Notes. - The above treatment was based on the holotypes of godmani and caelebs, and on 48 other specimens, several of which were compared to the types.

## 5a. Xyleborus sharpi sharpi Blandford

Ňyleborus sharpi Blandford, 1898, Biol. Centr. Amer., Coleopt. 4(6):199 (Lectotype, female: Paraiso, prol. Panama; British Mus. Nat. Hist., present designation)
Diagnosis.- This subspecies is exactly like s. lenis Wood except the face of the elytral declivity is densely, rather deeply punctured by minute impressed points.

Female.- Length $3.3-3.9 \mathrm{~mm}, 2.0$ times as long as wide; as in s. lenis except for surface sculpture of elytral declivity as noted in above diagnosis.

Distribution.- Costa Rica to Panama on the Atlantic slope.

COSTA RICA: Limón Province; Beverly, 26-VIll-63, 10 m, No. 154 , liana, S. L. Wood; Finca Boston, IN-64, Theobroma cacao, J. L. Saunders; Finca La Lola, 23-V1II-62, Theobroma cacao, J. L. Saunders; Guápiles, 22-VIII-66, 100 m , No. 119. Terminalia, S. L. Wood. Cartago Province: Tapantí, I7-VIII-6.3, 700 m, No. 107, tree branch, S. L. Wood. Heredia Province: Puerto Viejo, 12-III-64, 70 m , No. 480, liana, S. L. Wood. PANAMA: Barro Colorado Island, Canal Zone, 1938, C. Zetek; Madden Forest, Canal Zone, 2-J-64, 70 m , No. 367, tree limb, S. L. Wood; Ft. Clayton, 22-X11-63, 30 m , No. 320, tree limb, S. L. Wood; Cerro Campana, Code, 26-VI1$66,1000 \mathrm{~m}$, No. 32, tree branch, S. L. Wood.

Hosts.- Terminalia sp., Theobroma cacao, etc.

Biology.-As in perebeae.
Notes.- The above treatment was based on the three syntypes and on 56 other specimens. The female syntype from Paraiso is here designated as the lectotype. Blandford indicated that this specimen came from Guatemala; however, its structure is of the southern form; the country of origin is not indicated on the label. Because several reports on this southern race have been published under this name, the Paraiso specimen was selected as the lectotype rather than a representative of the less common northern race.

## 5b. Xyleborus sharpi lenis Wood

Xylchorus sharpi lenis Wood, 1974, Brigham Young U'niv. Sci. Bull., Biol. Ser. 19(1):35 (Holotype, female; 29 km E Coatzocoalcos, Veracruz, Mexico: Wood Coll.)
Diagnosis.- This species is almost identical to pandulus Wood. It is distinguished by the much finer punctures on the declivital face, by the smoother declivital surface (the surface is very irregular, with irregular serpentine lines in pandulus), and by the smaller, less abundant denticles on the ventrolateral margin of the declivity.

Female. - Length 3.3-3.9 mm, 2.0 times as long as wide; color dark brown.

Frons and pronotum essentially as in perebeae, except punctures on pronotal dise very slightly larger.

Elytra 1.1 times as long as wide, 1.3 times as long as pronotum; outline essentially as in godmani except apical emargination wider, not as deep: basic sculpture as in godmani except major spine stout, conical, pointed, largest denticle on basal margin closer to suture than to major spine; declivital area below major spine broadly elevated, denticles on posterolateral margin sparse, low, poorly formed; punctures on declivital face small, shallow, general surface between punctures shining, minutely irregular, spaces between punctures smooth, without impressed points. Vestiture as in godmani.

Distribution. - Veracruz to Chiapas.
MEXICO: Chiapas: 13 km N Ocosingo, 2-V1-69; 21 km N Ocozocoautla 2-VII-69, Palenque Ruins, 9-V-69: all by D. E. Bright. Oaxaca: Valle Nacional. Veracruz: 29 km E Coatzocoalcos, $26-\mathrm{VI}-67,30 \mathrm{~m}$. No. 104, tree limb. S. L. Wood; Dos Amates, 5-V-69, D. E. Bright;

Lago Catemaco, 16-20-VI-69, D. E. Bright; 16 km NW Sontecomapan, 18-VI-69, D. E. Bright.

Biology.- As in perebeae.
Notes.- The above treatment was based on the holotype and on 33 other specimens. It differs from $s$. sharpi only by the minute surface sculpture of the elytral declivity.

## 6. Xyleborus sanguinicollis Blandford Fig. 182

Xyleborus sanguinicollis Blandford, 1898, Biol. Centr. Amer., Coleopt. 4(6):198 (Holotype, female; Bugaba, Chiriquí, Panama; British Mus. Nat. Hist.)
Diagnosis.- This species is distinguished from the rather distantly allied sharpi by the much lower position of the major declivital spines on the elytral declivity, by the larger size and more slender, pointed form of the major declivital spine, by the arrangement of minor declivital denticles, and by the rufescent pronotum, with black elytra.

Female.- Length $3.5-3.8 \mathrm{~mm}, 2.0$ times as long as wide; color black, with prothorax light reddish brown.

Frons and pronotum essentially as in perebeae except serrations on anterior margin of pronotum slightly larger; pronotum color reddish brown.

Elytra 1.1 times as long as wide, 1.2 times as long as pronotum; disc occupying 40 percent of elytral length, about as in perebeae. Declivity much as in sharpi, broadly excavated, sulcate on median third; basal margin abrupt, armed by five pairs of denticles from suture to interstriae 3, middle one distinctly larger; major spine slightly below middle, in line with interstriae 3, very large, moderately stout, sharply pointed, its base rising gradually from more than a third of declivital area on each elytron; a few minor denticles at base of interstriae 4 and 5, those on 5 continuing along declivital margin almost to suture, final one slightly larger than others; punctures on face of declivity very small, obscure, general surface densely punctured by minute points. Vestiture as in godmani.

Male. - Length 3.0-3.6 mm; pronotum as in male perebeae and sharpi; elytra as in female except most minor denticles absent.

Distribution.- Costa Rica to NW Panama on the Pacific slope.

COSTA RICA: San Ignacio de Acosta, San José, 5-VII$63,1600 \mathrm{~m}$, No. 38, tree sapling, S. L. Wood; San Isidro
del General. 13-XII-63, 1000 m , No. 280, tree branch, S . L. Wood; Río Damitas, Dota Mts., San José, 18-II-64, 250 m , No. 436, tree sapling, S. L. Wood; Finca Gromaco, Puntarenas, 14 -VII- $63,500 \mathrm{~m}$, No. 80 , tree seedling, S. L. Wood; Volcán, Puntarenas, II-XII-63, 1000 m, No. 305, Humaro, S. L. Wood; Dominical, Puntarenas, 9-Xil-63, 3 m , No. 301, tree limb, S. L. Wood; Rincón de Osa, Puntarenas, 11-VIIl-66, 30 m , No. 69, Vismia, S. L. Wood. PANAMA: Bugaba, Chiriquí, G. C. Champion.

Hosts.- Vismia sp., etc.
Biology.-As in perebeae.
Notes.- The above treatment was based on the holotype, on my 2 homotypes, and on 36 other specimens.

## 7. Nyleborus ebenus Wood <br> Fig. 182

Xyleborus ebenus Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):39 (Holotype, female: Guápiles, Limón, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from sanguinicollis Blandford by the black prothorax by the smooth, shining surface of the lower elytral declivity, and by the distinctly impressed declivital punctures.

Female.- Length 3.7-3.9 mm, 2.0 times as long as wide; color black. As in sanguinicollis except as noted in above diagnosis.

Male.- Differing from male sanguinicollis in same characters as for females.

Distribution.- Atlantic slope of Costa Rica to Pacific slope of Panama and Colombia.

COSTA RICA: Guápiles, Limón, 22-VII-66, 100 m . No. 110. 113, tree sapling, S. L. Wood; Zant, Limón, 30-V-48, Theobroma cacao, Salas; Turrialba, Cartago, 9-III$66,700 \mathrm{~m}$, No. 460, tree sapling, S. L. Wood. PANAMA: Cerro Punta, Chiriquí, 11-I-64, $2800 \mathrm{~m}, \mathrm{~S}$. L. Wood; Cerro Campana, Cocle, 26-VII-66, 1000 m , No. 32, tree branch, S. L. Wood. COLOMBIA: 8 km S Colonia (near Buenaventura), Valle de Cauca, 9-VII-70, 30 m , No. 619 in Poutcria, No. 636 in Protium nercosum, S. L. Wood.

Hosts.- Pouteria sp., Protium nervosum, Theobroma cacao, etc.

Biology.- As in perebcae.
Notes.- The above treatment was based on the type series of 25 specimens and on 32 other specimens.

## 8. Xyleborus obesus LeConte

 Fig. 187Nyleborus obesus LeConte, 1868. Trans. Amer. Ent. Soc. 2:159 (Lectotype, female; Virginia; Mus. Comp. Zool., 989, present designation)

Xyleborus serratus Swaine, 1910, Canadian Ent. 42:162 (Lectotype, female; Ste. Anne de Bellevue, Quebec; Canadian Nat. Coll., 9327, designated by Bright, 1967, Canadian Ent. 99:680); Hopkins, 1915, U.S. Dept. Agric. Rept. 99:69. Synonymy
Anisandrus populi Swaine, 1917, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(1):22 (Lectotype, female; Ste. Anne de Bellevue, Quebec; Canadian Nat. Coll., subsequent designation by Bright, 1967, Canadian Ent. 99:673); Schedl, 1964, Reichenbachia 3:314. Synonymy
Diagnosis.- This species is distinguished from dispar (Fabricius) by the presence of three to five denticles on the posterolateral margin of the elytral declivity, and by the slightly larger punctures on the pronotal dise. Most specimens appear much stouter than dispar, but this character is not consistent.

Female. - Length $2.8-3.5 \mathrm{~mm}, 2.0-2.2$ times as long as wide; color very dark brown, almost black.

Frons broadly convex, slightly, transversely impressed above epistoma; surface reticulate, punctures rather small, shallow, moderately close; vestiture inconspicuous, hairlike.

Pronotum 0.93 times as long as wide; widest on basal third, sides rather strongly arcuate, broadly rounded anteriorly, slightly produced near median line; anterior margin armed by four (rarely six) rather coarse serrations; summit at middle, broad; anterior half rather coarsely asperate; posterior areas reticulate, fine- and medium-sized punctures intermixed, rather shallow. Vestiture hairlike, short on disc, long on lateral and anterior margins.

Elytra 1.1 times as long as wide, 1.3 times as long as elytra; sides straight and parallel on basal three-fourths, obtusely subangulate behind; striae not impressed, punctures moderately coarse, rather deep; interstriae smooth, shining, twice as wide as striae, punctures rather fine, confused. Declivity steep, broadly convex; striae slightly impressed, about as on disc; interstrial punctures uniseriate, very finely granulate; subapical posterolateral margin subacutely elevated from a point in line with striae 2 to interstriae 7, its crest tuberculate, three to five tubercles moderately coarse. Vestiture of rows of very small strial hair, and of fine, long, moderately abundant interstrial hair; longest setae almost twice as long as an interstriae.

Male.- Length $1.5-1.8 \mathrm{~mm}$; dwarfed, strongly convex; head basically as in female; pronotum outline as in female, much more broadly convex, summit indefinite, almost devoid of asperities, surface, smooth, shining, anterior margin unarmed; elytra declivous almost from base, striae and interstriae as in female, posterolateral margin very feebly elevated, granules almost obsolete.

Distribution.- Minnesota and Quebec to West Virginia.

CANADA: Ontario: Ottawa. Quebec: Ft. Coulogne, Ile Perrot, Kings Mtn., Ste. Anne's. USA: Connecticut: Hampton. Minnesota: Hennepin Co., Itasca Park, Ramsey Co. Wisconsin: Clintonville.

Hosts.-Fagus grandifolia, Populus tremuloides, and Quercus sp.

Biology.- Evidently as in dispar.
Notes.- The above treatment was based on the 2 syntypes of obesus in the LeConte collection, on 4 topotypic homotypes (possibly syntypes), and on 81 other specimens. The first syntype in the LeConte series, from Virginia, is here designated as the lectotype of obesus LeConte. It bears a red type label, Type No. 989, and has been regarded as the type for many years, although not previously so designated.

## 9. Xyleborus dispar (Fabricius) <br> Fig. 187

Apate dispar Fabricius, 1792, Entomologia systematica emendata et aucta, secundum classes . . . 1(2):363 (Syntypes; Germany; Copenhagen Mus.; not examined)
Bostrichus brevis Panzer, 1793, Fauna Germanica 8:34 (Syntypes?; Germany); Hagedorn, 1910, Coleopt. Cat. 4:102. Synonymy
Bostrichus thoracicus Panzer, 1793, Fauna Germanica 8:34 (Syntypes?; Germany); Hagedorn, 1910, Coleopt. Cat. 4:102. Synonymy
Scolytus pyri Peck, 1817, Massachusetts Agric. J. 4(3):207 (Syntypes?; Massachusetts; presumably lost); Schedl, 1960, Coleopterists Bull. 14(1):11. Synonymy
Bostrichus tachygraphus Sahlberg, 1834, Dissertatio entomologica insecta Fennica enumerans, p. 52 (Syntypes?); Hagedorn, 1910, Coleopt. Cat. 4:102. Synonymy
Bostrichus ratzeburgi Kolenati, 1846, Meletemata Ent. 3:39 (Syntypes?); Ferrari, 1867, Die Forst- und Baunzuchtschädlichen Borkenkäfer, p. 27. Synonymy
Anisandrus swainei Drake, 1921, Ohio J. Sci. 21:203 (Holotype, female; New York; U.S. Nat. Mus.); Wood, 1957, Canadian Ent. 89:403. Synonymy
Xyleborus cerasi Eggers, 1937, Ent. Blätt. 33:335 (Holotype, female; Montella, Avellino, Italy; deposited
in but not now in Eggers Coll., presumably on loan to Schedl); Schedl, I964, Reichenbachia 2:220. Synonymy
Diagnosis.- This species is distinguished from obesus LeConte by the absence of denticles on the posterolateral margin of the elytral declivity, and from sayi (Hopkins) by the larger body size and by the larger numbers of serrations arming the anterior margin of the pronotum.

Female.- Length $2.8-3.5 \mathrm{~mm}, 2.2$ times as long as wide; color dark brown to black.

Frons and pronotum as in obesus except anterior margin of pronotum armed by six to eight serrations and punctures on posterior areas of pronotum uniformly small.

Elytra as in obesus except declivity not quite as steep, interstrial granules on declivity averaging slightly larger, and elevated subapical posterolateral margin slightly, minutely sinuate, not actually serrate or armed by denticles; vestiture hairlike, longest setae little if any longer than width of an interstriae.

Male.- As in male of obesus except anterior margin of pronotum feebly serrate and anterior slope of pronotum more coarsely asperate; setae on median half of elytra very short.

Distribution.- British Columbia and Nova Scotia to Utah and Virginia; introduced from Europe.

CANADA: British Columbia: Bowser, Creston, Langley Prairie, Nanaima, Royston, Squamish, Vancouver. Nova Scotia: Ann Valley, Cornwallis, Gap Valley, Halifax. Ontario: Ridgeway. USA: District of Columbia: Washington. Idaho: Coeur d'Alene, Moscow, Plummer. Maine: Orono, Paris, Strong. Maryland: Annapolis, Melrose Highlands. Massachusetts: Chicopee, Natick, Petersham. Michigan: Agricultural College, Elberta, Mt. Clemens, Shelby. New Jersey: Clemton, Jamesburg, Morristown, Newark, Orange Mtn., Rutherford, Westville. New York: Albany, Cranberry Lake, Forestburg, Lockport, Peekskill, Staten Island, West Point. North Carolina: Wakefield. Ohio: Clarksburg, Euclid, Minerva, Perry. Oregon: Beaverton, Carlton, Forest Grove, Polk Co., Talent. Pennsylvania: Burning Well, Eagles Mere Park, Forest Dale, Milford, Montebello, Morrisville, Promised Land, Tannersville. Rhode Island: Kingston. Utah: Logan Canyon, Milton in Morgan Co., Hobble Creek in Utah Co., Salt Lake City. Virginia: Falls Church, Rosslyn. Washington: Blaine, Dole, Enumclaw, Puyallup, Richmond Beach. West Virginia: Bayard, Randolph Co.

Hosts.-Acer nigrum, A. platanoides, A. saccharinum, Betula fontinalis, B. papyrifera, Castanea dentata, Corylus sp., Juglans sp.,

Malus spp., Prunus sp., Pyrus communis, Quercus spp., Salix sp., Vitis sp.

Biology.- Unthrifty or injured limbs and boles $5-20 \mathrm{~cm}$ in diameter or larger are selected for attack. The female constructs a short, radial entrance tunnel from which two transverse egg galleries branch about $1-3 \mathrm{~cm}$ below the surface of the wood. In smaller material the tunnel may spiral rather than follow a transverse pattern. Short branch tunnels may extend from the main gallery; at times longitudinal branches may again branch on a transverse plane into two galleries resembling the original pair. At times this species has been an important pest in fruit orchards. This is the only species of Scolytidae known to have a true diapause.

Notes.- The above treatment was based on 7 European specimens and on 414 American specimens. They agree with specimens identified as dispar by Eggers, who studied the type series, and with LeConte's specimens of pyri, which agree with those of Fitch, Harris, and Schwarz. The holotype of swainei was examined and compared to my material.

## 10. Xyleborus sayi (Hopkins)

Fig. 187
Xyleborus obesus var. minor Swaine, 1910 (nec. Stebbing, 1909), Canadian Ent. 42:164 (Lectotype, female; Ste. Anne de Bellevue, Montreal Island, Quebec; Canadian Nat. Coll., 9315, subsequent designation by Bright, 1967, Canadian Ent. 99:680)
Anisandrus sayi Hopkins, 1915, U.S. Dept. Agric. Rept. 99:68 (Holotype, female; Morgantown, West Virginia; U.S. Nat. Mus., 7432); Wood, 1957, Canadian Ent. 89:403. Synonymy
Xyleborus neardus Schedl, 1950, Ann. Mag. Nat. Hist. (12)3:893. Replacement name for winor Swaine

Diagnosis.- This species is distinguished from dispar (Fabricius) by the smaller body size and by the smaller number of serrations arming the anterior margin of the pronotum.

Female.- Length 2.3-2.6 mm, 2.2 times as long as wide; color dark brown to almost black.

As in dispar except anterior margin of pronotum armed by two to six serrations, median pair much larger; declivital striae less distinctly impressed, punctures averaging slightly smaller; elytral vestiture as long as in dispar, slightly more abundant.

Male.- Length 1.3 mm ; as in male dispar except anterior margin of pronotum unarmed, asperities on anterior slope smaller; vestiture about as in female.

Distribution.- Ontario and Quebec to Missouri and Georgia.

CANADA: Ontario: Fletcher, Ottawa, Toronto. Quebec: Knowlton, Ste. Anne de Bellevue. USA: Connecticut: Lyme. District of Columbia: Washington. Indiana: Shoals. Kentucky: Cumberland St. Pk. Maine: Strong. Maryland: Great Falls, Silver Spring. Michigan: Detroit. Missouri: Dent Co. New Jersey: Anglesia, Red Bank. New York: Buffalo, Ithaca, Syracuse, West Point. North Carolina: Cherokee, Pink Beds, Tryon, Whitesides Mtn. Ohio: Hocking Co. Pennsylvania: Clark's Valley, La Port. Tennessee: Gatlinburg, Tellico Plains. Virginia: Falls Church, Rosslyn. West Virginia: Dellslow, French Creek, Morgantown, Pocahontas Co., Webster Co.

Hosts.-Acer rubrum, A. sp., Betula papyifera, B. sp., Castanea spp., Cormus sp., Fagus sylvatica, Kalmia latifolia, Lindera benzoin, Nyssa sp., Sassafras albidum.

Biology.- Evidently as in dispar except that smaller limbs and branches are attacked.

Notes. - The above treatment was based on 4 paralectotypes of minor, on the holotype of sayi, and on 160 other specimens.

## 11. Xyleborus horridus Eichhoff <br> Fig. 183

Xylchorus horridus Eichhoff, 1869, Berliner Ent. Zeitschr. 12:282 (Lectotype, female; Teapa, Mexico; Brussels Mus., present designation)
Xyleborus flohri Schedl, 1972, Koleopt. Rund. 50:69 (Holotype, female; Mexico; Schedl Coll.); Wood, 1977. Great Basin Nat. 37:211. Synonymy

Diagnosis.- This species is distinguished from the closely related horridatus Wood by the larger average size, by the absence of a predeclivital impression on the basal half of the elytra, by the much more abundant elytral vestiture, particularly on the declivity, and by the larger tubercles on declivital interstriae 3 , and by the distribution.

Female.- Length $3.8-4.2 \mathrm{~mm}, 2.3$ times as long as wide; color dark reddish brown.

Frons broadly convex, a weak, transverse impression above epistoma; surface reticulate, punctures rather small, close, obscurely impressed, subgranulate on lower half; vestiture of fine, sparse hair.

Pronotum 1.0 times as long as wide; widest on basal third, sides moderately arcuate, distinctly converging toward broadly rounded anterior margins; anterior margin armed by

8-12 low serrations; summit broad, slightly behind middle; anterior slope rather coarsely, closely asperate; posterior areas smooth, shining, punctures moderately fine, rather deep, close. Vestiture of fine, rather short hair.

Elytra 1.5 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal two-thirds, converging very slightly, then very broadly rounded behind; disc occupying very slightly more than basal half of elytra; striae 1 feebly, others not impressed, punctures small, distinctly impressed; interstriae smooth, shining, obscure indications of impressed lines, four times as wide as striae, punctures strongly confused, rather close. Declivity broadly impressed, rather gradual and narrower on its basal half; steeper and more nearly subconcave on its apical half, surface smooth, shining, and densely, coarsely, rather shallowly covered by confused punctures; position of interstriae 1

Fig. 18.3. Xyleborus spp., female declivities with setae omitted: A, horridus; B, horridatus.
armed by a row of 3-5 rather coarse, stout, pointed tubercles, those near base and apex smaller; position of interstriae 3 armed by a row of 6-8 smaller denticles; lateral areas attaining a rounded summit at about interstriae 4; posterolateral margin suacutely elevated from apex to about interstriae 5. Vestiture of rather abundant, fine, rather long hair; more abundant on declivity; slightly longer on sides.

Distribution.-S Texas to Guatemala.
USA: Texas: Brownsville, 3-VI, II-V, 3-VI-32; Hidalgo Co., 20-III-52, D. J. and J. N. Knull. MEXICO: Tabasco: Teapa, Salle. Veracruz: El Palmar, 4-IV-57, Hetea brasiliensis, R. Coronado, and 22-III-58, Herea brasiliensis, E. Topete. GUATEMALA: Pantaleon, G. C. Champion.

Hosts.-Hevea brasiliensis, etc.
Notes.- The above treatment was based on the 2 female syntypes in the Brussels Museum and on 22 other specimens. The second of these syntypes is from Teapa and is here designated as the lectotype of this species.

## 12. Xyleborus horridatus Wood Fig. 183

Xyleborus horridatus Wood, 1967, Great Basin Nat. 27:135 (Holotype, female; San Isidro del General, San José, Costa Rica; Wood Coll.)
Diagnosts.- This species is distinguished from the closely related horridus Eichhoff by the smaller average size, by a predeclivital impression that may begin on the basal fourth of the elytra, by the less abundant elytral vestiture, by the smaller denticles on declivital interstriae 3 , and by the distribution.

Female.- Length $3.4-4.0 \mathrm{~mm}, 2.3$ times as long as wide; color rather dark reddish brown.

Frons and pronotum as in horridus except anterior margin armed by 10-14 low serrations.

Elytra as in horridus except declivity commencing anterior to middle of elytral length, a predeclivital impression on interstriae 1 and 2 sometimes extending to basal fourth; denticles on declivital interstriae 1 about 2-4 in number, averaging slightly smaller in size, denticles on other interstriae much smaller, mostly obsolete; vestiture on elytral disc shorter, less abundant, very sparse, almost obsolete on declivity.

Male.- Length 3.3-3.5 mm; head and elytra much as in female except characters poorly formed, elytral declivity commencing
on basal fourth, all denticles virtually obsolete, posterolateral margin rounded; pronotal asperities almost obsolete, anterior half of pronotum deeply, concavely excavated, anterior margin smooth, strongly, acutely elevated and produced into an acute median process.

Distribution.- Costa Rica to Colombia.
COSTA RICA: San Isidro del General, 5-XII-63, 1000 m, No. 277. Citrus, S. L. Wood; Dominical, Puntarenas, 9-XII-63, 3 m , No. 296, liana, S. L. Wood; Guápiles, Limón, 22-VIII-66, 100 m , No. 125, Theobroma cacao, S. L. Wood; Pandora, Limón, 23-VII-63, 50 m , No. 135, tree limb, S. L. Wood; Hamburgfarm on Río Reventazón, Santa Clara, Limón, 10-VI-23, Nevermann. PANAMA: Barro Colorado Island, Canal Zone, 26-II-29, S. W. Frost. COLOMBIA: Finca El Canto, La Plata, Huila, 28-IN-59, naranjo dulce, B. Humides.

Hosts.-Citrus sinensis, Theobroma cacao, etc.

Biology. - Unthrifty limbs $5-10 \mathrm{~cm}$ in diameter were attacked. The mature gallery system consisted of a mass of bifurcately branched and rebranched tunnels. The entire system was rather compact, with none of the short branches extending more than a few centimeters from the original entrance tunnel.

Notes.- The above treatment was based on the type series of 35 specimens and on 5 additional specimens.

## 13. Xyleborus (Neoxyleborus) palatus Wood

Xyleborus palatus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):35 (Holotype, female; 24 km W Armeria, Colima, Mexico; Wood Coll.)
Diagnosis.- This species is but remotely related to other species groups included here in the subgenus Neoxyleborus. It differs from other species treated here in this group by the steeper, flat elytral declivity, and by the arrangement of declivital denticles.

Female.- Length $1.8-2.1 \mathrm{~mm}, 2.3$ times as long as wide; color very dark brown to black.

Frons broadly concave, a slight, transverse impression above epistoma; surface strongly reticulate, punctures small, shallow, sparse.

Pronotum 1.1 times as long as wide; sides feebly arcuate, almost parallel on basal twothirds, rather broadly rounded in front; anterior margin armed by 6 to 10 serrations, median one or two pairs distinctly larger; summit at middle; anterior area rather coarsely asperate; posterior areas mostly reticulate
with some shining areas, punctures rather small, shallow, moderately close. Vestiture of moderately abundant, fine, short hair.

Elytra 1.4 times as long as wide, 1.3 times as long as pronotum; sides almost straight and parallel on slightly more than basal twothirds, rather narrowly rounded behind; disc occupying basal 60 percent of elytral length; striae not impressed, punctures rather small, moderately deep, spaced within a row by one to two diameters of a puncture; interstriae almost smooth, shining, about three to four times as wide as striae, punctures very fine, slightly confused on basal two-thirds of dise, uniseriate toward declivity. Declivity rather steep, flat on median half from rounded base to near apex; surface shagreened; striae as on disc, apices of 2 and 3 diverge toward suture; interstriae $1-3$ flat; all interstriae with rows of small, pointed granules, those near base on all interstriae larger, those on 1 and 2 on face of declivity and on lower half of 5,7 , and 8 minute, others slightly larger; posterolateral margin rounded, marked by a row of small tubercles from apex to interstriae 9 . Vestiture of minute strial hair on and near declivity, and interstrial bristles each as long as distance between rows on and near declivity, confused on anterior areas of disc.
Distribution.- Nayarit to Colima.
MEXICO: Colima: 53 km S Colima, 27-VI-65, 700 m , No. 125 in flight, S. L. Wood; 24 km W Armeria, 30-VI$65,30 \mathrm{~m}$, No. 147 in flight, No. 153 in a tree branch, S. L. Wood; 6 km S Cihuatlán, Colima, 30-VI-65, 70 m , No. 157. liana, S. L. Wood. Jalisco: Volcán Colima, 23-VI-65, 2500 m , No. 124, shrub limb, S. L. Wood. Nayarit: Laguna Santa María, 6-V1I-65, 1000 m , No. 193, liana, S. L. Wood; 8 km E San Blas, 12-VII-65, 70 m , No. 232, leguminose tree, S. L. Wood.

Biology.- Unthrifty limbs and branches were attacked.

Notes.- The above treatment was based on the type series of 24 specimens.

## 14. Xyleborus (Neoxyleborus) squamulatus Eichhoff

Xyleborus squamulatus Eichhoff, 1869, Berliner Ent. zeitschr. 12:282 (Holotype, female; Brazil; Brussels Mus.)
Diagnosis. - This species is distinguished from the distantly related spinulosus Blandford by the broadly impressed, shallowly concave elytral declivity on which strial punctures are obsolete, by the abundant, short,
confused declivital scales, and by the uniformly small declivital denticles.

Female.- Length $1.7-2.3 \mathrm{~mm}, 2.5$ times as long as wide; color very dark brown to almost black.

Frons as in palatus Wood.
Pronotum 1.1 times as long as wide; widest just behind middle, sides moderately arcuate on basal two-thirds, rather broadly rounded in front; anterior margin armed by $12-16$ narrow, rather low serrations; summit rather broad, at middle; anterior slope rather coarsely, not closely asperate; entire surface reticulate except asperities; posterior areas with fine, shallow, widely spaced punctures. Vestiture of fine, rather sparse, moderately short hair.

Elytra 1.5 times as long as wide; 1.3 times as long as pronotum; sides almost straight and parallel on basal half, then gradually narrowed to just before rather broadly rounded apex; disc occupying slightly less than basal half of elytral length; striae 1 slightly, others weakly to feebly impressed, punctures rather small, close, moderately deep; interstriae smooth, shining, about three times as wide as striae, punctures fine, uniseriate, replaced by tubercles toward base of declivity. Declivity gradual, broadly, subconcavely impressed; all margins rounded; declivital face with dense, fine, confused squamiferous punctures, striae obsolete; interstriae 1-9, on basal and lateral margins each armed by about two to four sharply pointed denticles, length of largest about equal to one-half width of an interstriae, those on posterolateral margin continuing almost to suture. Vestiture on dise of rows of fine strial and interstrial hair; on declivity of small scales, each scale about one and one-half to two times as long as wide.

Distribution.- Chiapas to Brazil.
MEXICO: Chiapas: 8 km SW El Bosque, 3-VII-69, D. E. Bright. GUATEMALA: Palín, Esquintla, 19-V-64, 300 m, No. 684, Inga, S. L. Wood; Cerro Zunil, G. C. Champion. COSTA RICA: Cartago, Cartago, 30-X-63, 1900 m , No. 249, tree seedling, S. L. Wood; Tapantí, Cartago, 2-V1I-63, 1300 m , No. 10, Conostegia oerstediana, S. L. Wood. OTHER COUNTRIES: Colombia, Venezuela, Brazil.

Hosts.- Conostegia oerstediana, Inga, etc.
Biology.- Specimens were taken from material $5-8 \mathrm{~cm}$ in diameter.

Notes.- The above treatment was based on the holotype and on 87 other specimens.

## 15. Xyleborus (Neoxyleborus) spinulosus

 BlandfordXyleborus spinulosus Blandford, 1898, Biol. Centr. Amer., Coleopt. 4(6):201 (Lectotype, female; San Geronimo, Guatemala; British Mus. Nat. Hist., present designation)
Xyleborus fusciseriatus Eggers, 1934, Ent. Blätt. 30:82 (Holotype, female; La Caja, 8 km W San José, San José, Costa Rica; Berlin Mus.); Wood, 1979, Great Basin Nat. 39:137. Synonymy
Xyleborus spinosulus Schedl, 1934, Stylops 3:178 (Holotype, female: Honolulu, Hawaiian Islands; F. C. Hadden Coll.); Wood, 1966, Great Basin Nat. 26:32. Synonymy
Xyleborus artespinulosus Schedl, 1935, Arch. Inst. Biol. Veg. Río de Janeiro 2:93 (Syntypes, females; Hamburgfarm on Río Reventazón, Santa Clara, Limón, Costa Rica; Schedl and Nevermann colls.); Wood, 1979, Great Basin Nat. 39:I37. Synonymy
Diagnosis.- This species is distinguished from ferox Blandford by the smaller average size, by the more variable, more numerous, shorter, stouter declivital spines, and by the less strongly excavated declivity.

Female.- Length 1.8-2.6 mm, 2.6 times as long as wide; color dark brown to almost black.

Frons and pronotum as in palatus Wood except curvature of anterior margin of pronotum variable, armed by $8-12$ low serrations; reticulation on pronotal disc more conspicuous, smooth areas often obsolete.

Elytra 1.5 times as long as wide, 1.3 times as long as pronotum; sides almost straight and subparallel on slightly less than basal half, gradually tapered to half its width; apex shallowly emarginate on median third of elytral width; disc occupying basal 40 percent of elytral length; striae not impressed, punctures small, moderately impressed; interstriae smooth, shining, three to four times as wide as striae, punctures rather small, widely spaced, uniseriate. Declivity gradual, rather broadly excavated; striae 1 and 2 clearly indicated by punctures similar to those on disc; suture weakly elevated, 2 strongly impressed, gradually ascending to broad, rounded, moderately elevated summit on 3 and 4 (much higher than suture), elevation continued to apical margin in line with striae 2 ; interstriae 1 and 2 armed by one to three small, pointed denticles at base, minute granules may also continue to middle of declivity, 3 armed by
about six denticles of increasing size, lower one usually much larger, almost equal in length to width of a discal interstriae, located near middle of declivity; 4 and 5 with series of very small denticles continuing to near apex of lateral elevation, apex of lateral elevation armed by one to three larger spines similar to major spine on 3; these major spines may vary within series, between series, and on opposite sides of one specimen. Vestiture consisting of interstrial rows of hair on disc, of rows of scales on declivity; each scale about four to six times as long as wide, about half to two-thirds as long as distance between rows.

Male.- Length 1.5 mm ; basically similar to female except pronotal summit indefinite, asperities obsolete, anterior area punctured, broadly convex, anterior margin unarmed; elytral declivity much less strongly impressed, all granules and denticles obsolete; all characters less perfectly formed.

Distribution.- Jalisco to Brazil, and Hawaii.

MEXICO: Chiapas: Ocozocoautla. Jalisco: Atenquique. Nayarit: San Blas. Veracruz: Dos Amates, Lago Catemaco, Sontecomapan. GUATEMALA: Palín in Esquintla. HONDURAS: Zamorano. COSTA RICA: Cañas and Liberia in Guanacaste, Dominical and Rincón de Osa in Puntarenas, San Isidro del General, Santa Ana, Río Damitas (Dota Mts.), and Playón in San José, Beverley and Guápiles in Limón. OTHER AREAS: Venezuela, Brazil, Hawaii.

Hosts.-Bursera simarubra, Cecropia sp., Ochroma sp., Terminalia sp., etc.

Biology.- Unthrifty, cut, or broken seedlings, limbs, and branches of trees and lianas are infested by this species. The tunnels evidently are similar to those of Xylosandrus.

Notes.- The above treatment was based on the type series of spinulosus, on the syntype of artespinulosus in the Schedl collection and one in the Eggers collection, on the "paratype" of spinosulus in the Schedl collection, and on 157 American and 21 Ha waiian additional specimens, several of which were compared directly to the type material. Of the 5 syntypes now in the British Museum (Natural History), the first, a female from San Gerónimo, Guatemala, was labeled "Type" many years ago but has never officially been so designated. I here designate that female as the lectotype of spinulosus Blandford.

## 16. Xyleborus (Neoxyleborus) ferox Blandford

Xylebortus ferox Blandford, 1898, Biol. Centr. Amer.. Coleopt. 4(6):201 (Holotype, female; Bugaba, Chiriquí, Panama; British Mus. Nat. Hist.)
Diagnosis. - The exceedingly large declivital spines distinguish this species; other features are mentioned in the key and in the diagnosis of spinulosus Blandford.

Female.- Length 2.4-2.9 mm, 2.5 times as long as wide; color very dark brown.

Frons and pronotum as in spinulosus; anterior margin of pronotum armed by 10-14 low serrations; shining areas may predominate on pronotal disc.

Elytra as in spinulosus except dise occupying basal 50 percent of elytral length, declivity very slightly steeper, much more broadly excavated; declivity with strial punctures clearly impressed on 1 and 2 , a few punctures on 3 and 4 indicated; interstriae 1 , 2,3 , and 4 each with one or two small pointed denticles on basal margin, 3 also bearing an extremely large major spine just above middle of declivity, spine at least two and one-half times as long as its basal width and equal in length to distance from discal suture to striae 3 ; interstriae 5 with about three denticles on lateral margin, 6 with about three similar denticles followed near apex by another very large major spine similar to that on 3, a final minor denticle on posteromesal side of major spine. Vestiture sparse, consisting of rows of interstrial hair on dise, of sparse rows of scales on declivity; each small scale about six to eight times as long as wide, about half as long as distance between rows; all vestiture commonly abraded.

Distribution.- Costa Rica to Colombia.
COSTA RICA: Rincón de Osa, Puntarenas, lI-ViII$66,30 \mathrm{~m}$, No. 55, Ochroma, S. L. Wood; Playón, San José, 9-VIII-63, 50 m , No. 120, Ochroma, S. L. Wood; Beverley, Limón, 26-VIII-63, 10 m , No. 154, liana, S. L. Wood; Finca La Lola, Limón, 15-III-63, Thcobroma cacao, J. L. Saunders. PANAMA: Concepción, Chiriquí, 7-I-64, 100 m , No. 37, Ochroma, S. L. Wood; Pearl Island, 9-VlII-44, at light, J. P. Morrison. COLOMBIA: Finca Montegrande, Caicedonia, Valle de Cauca, 19-VI59, Coffea arabica, J. Restrepo; Atanguea, 10-XI-3I, T. cacao, D. Villegas.

Hosts.-Coffea arabica, Ochroma sp., Theobroma cacao.

Biology.- Specimens were taken from dying limbs $5-15 \mathrm{~cm}$ in diameter.

Notes.- The above treatment was based on the holotype of ferox and on 30 other specimens.

## 17. Xyleborus (Coptoborus) vespatorius Schedl

Coptoborus cmarginatus Hopkins, 1915 (nec Eichhoff, 1878), U.S. Dept. Agric. Rept. 99:53 (Holotype, female; Livingston, Guatemala; U.S. Nat. Mus., 7636)

Xyleborus vespatorius Schedl, 1931, Ann. Mag. Nat. Hist. (10)8:339 (Holotype, female; San Ignacio, Argentina; Schedl Coll.); Wood, 1972, Great Ba$\sin$ Nat. 32:200. Synonymy
Xyleborus corniculatus Schedl, I949, Rev. Brasil Biol. 9:275 (Holotype, female; Santa Catarina, Brazil; Schedl Coll.); Schedl, 1952, Ent. Blătt. 47-48:163. Synonymy
Xyleborus corniculatulus Schedl, 1949. Rev. Brasil Biol. 9:275 (Holotype, female; Trinidad: Schedl Coll.); Wood, 1972, Great Basin Nat. 32:200. Synonymy
Diagnosis.- This species is not closely related to other species treated here. It differs by the narrowly, strongly excavated elytral declivity with its lateral margins armed by a series of rather coarse denticles.

Female.- Length 2.3-2.7 mm, 3.2-3.4 times as long as wide; color reddish brown.

Frons broadly convex; surface reticulate, punctures small, shallow, moderately abundant, partly replaced on lower half by fine granules.

Pronotum 1.3 times as long as wide; sides almost straight and parallel on basal twothirds; summit well in front of middle; anterior third strongly declivous, coarsely asperate; anterior margin armed by about 6-10 low serrations; posterior areas mostly smooth, shining, with some indications of reticulation in most specimens, punctures very small, sparse, shallow. Vestiture hairlike, largely confined to marginal areas.

Elytra 2.1 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on slightly more than basal third, gradually tapered to level of sutural apex to half greatest elytral width, then abruptly rounded and obtusely, rather deeply emarginate at suture; dise occupying very slightly more than basal half of elytral length; striae not impressed, punctures small, shallow, distinct; interstriae almost smooth, shining, about three to four times as wide as striae, punctures uniseriate, rather widely spaced, fine to almost obsolete. Declivity gradual, rather narrowly, strongly excavated, lateral margins weakly elevated at base, becoming strongly elevated toward apex; striae 1 and 2 indicated by very shallow punctures, each
very slightly larger than on disc; suture feebly elevated, interstriae 2 impressed on median side, gradually ascending to narrow summit on 3; interstriae 2 with one or two granules at base, 3 armed by three to five denticles and, usually, a few minor granules, largest denticle usually slightly below middle of declivity, lowest denticle near apex. Vestiture of rows of erect, moderately long hair, rather stout on declivity.

Male.- Length 1.8 mm ; similar to female, with all characters rather poorly formed, except anterior third of pronotum shallowly concave on median two-thirds; pronotal asperities reduced in concave area, a slight median tubercle on unarmed anterior margin.

Distribution.- Veracruz to Argentina.
MEXICO: Veracruz: El Palmar, 22-IIl-57, Hevea brasiliensia, E. Topote, COSTA RICA: Turrialba, Cartago, 5-VII-63, 700 m , No. 22, tree branch, S. L. Wood; Guápiles, Limón, 22-VIII-66, 100 m , No. 102 , tree bole 30 cm diameter, S. L. Wood; Pandora, Limón, 23-V11I$63,50 \mathrm{~m}$, No. 135 , tree bole 15 cm diameter, S. L. Wood; Finca La Lola, Limón, 14-VIII-62, Thcobroma cacao, J. L. Saunders. OTHER COUNTRIES: Colombia, Venezuela, Trinidad, Brazil, Argentina.

Hosts.-Hevea brasiliensis, Theobroma cacao, etc.

Biology.- This species was taken from dying and recently cut limbs and boles $10-30$ cin in diameter. The simple entrance tunnel was expanded by the brood into a small tabular cavity that followed the grain of the wood.

Notes.- The holotypes of emarginatus, vespatorius, corniculatus, and corniculatulus were examined and the latter three were all compared to one another as well as to my specimens. Although small differences do occur between the unique types, all fall well within the limits of variation of this species. The declivital denticles on the holotype of vespatorius have been damaged, presumably from the chewing of siblings, thereby making its recognition a bit more difficult. The above treatment was based on 36 specimens in addition to the types.

## 18. Xyleborus (Coptoborus) catulus Blandford

[^15]Xyleborus intricatus Schedl, 1949, Rev. Brasil Biol. 9:274 (Holotype, female; Santa Catarina, Brazil; Schedl Coll.); Wood, 1975, Great Basin Nat. 35:23. Synonymy
Diagnosis.- This species could easily be placed in the subgenus Xyleborus near volvulus Fabricius; however, the small, slender form, the slender scutellum, and the declivity suggest a closer relationship to cuneatus Eichhoff. It is distinguished from cuneatus by the slightly steeper elytral declivity, with the apex slightly more broadly rounded and the marginal granules near the apex much smaller.
Female.- Length $1.6-1.7 \mathrm{~mm}, 2.9$ times as long as wide; color yellowish brown.

Frons essentially as in vespatorius. Pronotum 1.14 times as long as wide; essentially as in vespatorius except anterior margin very feebly serrate.

Elytra 1.7 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on slightly more than basal half, gradually converging on posterior half, narrowly rounded behind; disc occupying basal two-thirds; striae not impressed, punctures moderately large, shallow; interstriae smooth, shining, twice as wide as interstriae, punctures uniseriate, varying from minute to small on an interstriae. Declivity moderately steep, convex; strial punctures slightly larger than on disc, some punctures on 1 and 2 not in rows; interstriae 2 flat, not impressed, 1 and 3 each armed by two to four small denticles and usually two or three additional smaller granules, 2 with one to four minute granules, lateral interstriae with a few small granules and a total of about three small denticles; posterolateral margin rounded, subacute, and with two or three very small granules at apex of interstriae 1 and 2 ; apex not produced, more broadly rounded than in cuneatus. Vestiture largely confined to sides and declivity; on declivity of stout, rather short interstrial bristles, longest bristles about as long as distance between rows.

Distribution.- Panama to Brazil.
PANAMA: Limón Bay, Canal Zone, 30-Xll-63, 3 m , No. 354, tree limb, S. L. Wood; "Panama wood with orchids," intercepted at Mobile, Alabama, $24-\mathrm{V}-49$; Volcán de Chiriquí, G. C. Champion. VENEZUELA: 20 km SW El Vigia, Merida, 2l-X1-69, 50 m , No. 149 in tree limb, 10-XII-69, No. 187 in liana, S. L. Wood; 9 km S Barrancas, Barinas, 5-XI-69, 150 m , No. 100, Guazuma
ulmifolia, S. L. Wood. BRAZIL: Nova Teutonia, Santa Catarina, 1944.

Hosts.-Guazuma ulmifolia, etc.
Biology.- Specimens were taken from new tunnels in recently cut limbs and in boles $5-20 \mathrm{~cm}$ in diameter.
Notes.- The above treatment was based on the holotypes of catulus and intricatus, and on seven other specimens.

## 19. Xyleborus (Coptoborus) pseudotenuis Schedl

Fig. 184
Xyleborus pseudotenuis Schedl, 1936, Arch. Inst. Biol. Veget. 3:109 (Holotype, female; Brazil; Schedl Coll.)
Xyleborus tenuis Schedl, 1949, Rev. Brasil Biol. 9:269 (Holotype, female; Cordova, presumably Mexico; Schedl Coll.); Wood, 1976, Great Basin Nat. 36:349. Sunonymy
Xyleborus exilis Schedl, 1934, Ent. Blätt. 30:209 (Holotype, female; Halbinsel Osa, Costa Rica; Schedl Coll.). Possible synonym
Diagnosis.- This species is distinguished from the very similar cuneatus Eichhoff by the more narrowly produced elytral apices, with the posterolateral margin of the apex of interstriae 1 and 2 acutely elevated and almost entirely devoid of serrations.

Female.- Length $1.8-2.2 \mathrm{~mm}, 2.9$ times as long as wide; color yellowish brown.

Frons and pronotum as in catulus Blandford except pronotum 1.16 times as long as wide.

Elytra 1.8 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on slightly less than basal half, gradually converging to about one-third of greatest elytral width just before narrowly rounded posterior margin; dise confined to slightly more than anterior half; striae not impressed, punctures very small, shallow, spaced within a row by about two diameters of a puncture; interstriae almost smooth, shining, about four times as wide as striae, punctures uniseriate, shallow, very fine. Declivity gradual, convex; strial punctures shallow, much larger than on disc; interstriae 2 feebly impressed, 1 with about two small denticles and about three to five additional fine granules, 3 with about three small denticles and about three to six additional fine granules, these denticles and those in lateral areas of same size and position as in catulus; subapical posterolateral
margin subacutely elevated at apices of interstriae 1 and 2 , except shallowly, narrowly emarginate at suture, summit of elevation with one to three feeble granules indicated. Vestiture as in catulus.

Distribution.- San Luis Potosí and Veracruz to Venezuela and Brazil.

MEXICO: San Luis Potosí: 8 km or 5 miles N Tamazunchale, 22-XII-48, H. B. Leech. Veracruz: El Palmar, 22-III-58, Hevea brasiliensis, E. Topete; 5 km or 3 miles W Gutierrez Zamora, 25-VI-53, 70 m , S. L. Wood; Lago Catemaco. COSTA RICA: Guápiles, Limón, 22-VIII-66, 100 m , No. I20, Cordia, S. L. Wood; Pandora, Limón, 23-VIII-63, 50 m , No. I35, small log, S. L. Wood; Finca Los Diamantes, 7-II-63, Theobroma cacao, J. L. Saunders. PANAMA: Curundu, Canal Zone, 9-X-57, at light. OTHER AREAS: Brazil, Venezuela.

Hosts.-Cordia sp., Hevea brasiliensis, Theobroma cacao, etc.

Biology.- Specimens were taken from material $5-20 \mathrm{~cm}$ in diameter.

Notes.- The above treatment was based on 24 specimens, one of which was compared by me to the holotype of tenuis and on the holotype of pseudotenuis.

The female holotype of exilis Schedl (2.1 $\mathrm{mm})$ probably is of this species; however, the elytral declivity is very slightly steeper. Because this species varies in size, in steepness of the elytral declivity, in the size of certain declivital tubercles, and in the coarseness of the elytral vestiture, it appears best to await the collection of additional material before establishing synonymy of these two forms because the doubtful one bears the senior name.

## 20. Xyleborus (Coptoborus) cuneatus Eichhoff

Xyleborus cuneatus Eichhoff, I878, Mém. Soc. Roy. Sci. Liége (2)8:380 (Holotype, female; "Varinas, Nova Grenada," which presumably now is Barinas, Barinas, Venezuela; Schedl Coll.)
Diagnosis.- This species is distinguished from the closely allied pseudotenuis Schedl by the slightly less strongly produced elytral apices, with the posterolateral margin rounded and obscurely elevated throughout and armed by three or four rather coarse, somewhat widely spaced granules.

Female.- Length $1.6-1.7 \mathrm{~mm}, 2.9$ times as long as wide; color yellowish brown.

Frons and pronotum about as in catulus Blandford except pronotum 1.24 times as long as wide.

Elytra 1.7 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal two-thirds, then tapered, rather narrowly rounded behind; striae not impressed, punctures moderately coarse, rather shallow, spaced within a row by slightly more than diameter of a puncture; interstriae smooth, shining, slightly more than twice as wide as striae, punctures uniseriate, rather widely spaced. Declivity moderately steep, convex; striae not impressed, punctures equal in size to those on disc, very shallow; interstriae 2 somewhat flattened and devoid of granules except toward base, 1 with two small denticles; one near middle, one on lower fourth, a few granules toward base, 3 usually without denticles (one on left side of one specimen), about two to six small granules may be present; subapical ventrolateral margin rounded, weakly elevated, armed by three small denticles, one in line with each interstriae 1-3; shallowly emarginate at suture. Vestiture about as in pseudotenuis.

Distribution.- Panama to Peru.
PANAMA: Fort Sherman, Canal Zone, 10-XI-57, at light. PERU: Monson Valley, Tingo María, I0-XI-54, E. I. Schlinger and E. S. Rose. The type presumably is from Barinas, Venezuela.

Notes. - The above treatment was based on the holotype and on two other specimens. Evidently it is an extremely rare species.

## 21. Xyleborus (Coptoborus) exutus Wood

Xyleborus exutus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):36 (Holotype, female: Turrialba, Cartago, Costa Rica: Wood Coll.)
Diagnosis.- This species is distinguished from the allied tolimanus Eggers by the complete absence of denticles on the elytral declivity.

Female.- Length $1.9 \mathrm{~mm}, 3.0$ times as long as wide; color reddish brown, pronotum more yellowish brown.

Frons about as in catulus Blandford but surface finely granulate to well above eyes. Pronotum 1.2 times as long as wide; basically as in catulus except anterior margin rather narrowly rounded and more coarsely serrate.

Elytra 1.9 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal half, acutely converging to
one-fifth greatest elytral width at narrowly, shallowly emarginate apex; striae not impressed, punctures small, shallow, distinct, spaced within a row by twice diameter of a puncture; interstriae smooth, shining, three to four times as wide as striae, punctures fine, uniseriate, rather widely spaced. Declivity gradual, narrowly convex; striae feebly impressed, punctures slightly larger than on dise; all interstriae equally sculptured, punctures distinct, regularly, rather closely spaced, anterior margin of each rather broadly, weakly granulate; interstriae 1 weakly elevated near acuminate apex; posterolateral margin weakly elevated and rather narrowly rounded near apex, becoming more broadly rounded anteriorly, entirely devoid of granules and denticles. Vestiture entirely abraded except for a few hairlike setae on sides.

Distribution.- Costa Rica.
COSTA RICA: Turrialba, Cartago, 9-III-64, 700 m , No. 468, in a fence post, S. L. Wood.

Notes.- The above treatment was based on the holotype.

## 22. Xyleborus (Coptoborus) tolimanus Eggers

Xyleborus tolimanus Eggers, 1928, Arch. Inst. Biol. Sao Paulo 1:97 (Lectotype, female; Tolima, Colombia; U.S. Nat. Mus., 60765 , subsequent designation by Anderson and Anderson, 1971. Smithsonian Contrib. Zool. 94:34)
Diagnosis.- This species has the acutely acuminate elytral apex of exutus Wood, but it is distinguished by the acutely pointed denticles on declivital interstriae 1-3 and, particularly, on the posterolateral margin near the apex.

Frons and pronotum as in exutus except serrations on anterior margin of pronotum slightly larger and disc more nearly reticulate.

Elytra 2.0 times as long as wide, 1.6 times as long as pronotum; outline about as in exutus except serrate at apex; disc occupying basal half; striae not impressed, punctures small, moderately deep, spaced by almost twice diameter of a puncture; interstriae smooth, shining, punctures uniseriate, shallow, almost as large as those of striae, rather widely spaced. Declivity rather gradual, narrowly convex; striae very weakly impressed, punctures shallow, slightly larger than on
disc; interstriae 1-3 (and to a lesser extent those in lateral areas) armed by rather closely spaced, small, pointed denticles, much smaller toward base, largest near apex; subapical margin strongly, acutely produced near suture, its posterolateral margin acute at apex, becoming rounded anteriorly, armed by a series of closely set, acutely pointed denticles that appear continuous with those of interstriae 3 , final denticle at suture usually larger and often forming a flattened cusp. Vestiture confined to sides and declivity; on declivity consisting of rows of minute strial hair and rows of erect, rather coarse, interstrial hair, becoming more abundant and confused near apex, length of longest setae equal to up to almost twice distance between interstrial rows.

Male.- Length 1.6 mm ; pronotum 1.2 times as long as elytra and 1.7 times as long as wide; pronotum devoid of asperities, anterior third strongly excavated, anterior margin acutely elevated, almost straight except for obtuse median extension; elytra resembling female but stouter, with all characters poorly formed.

Distribution. - Veracruz to Brazil.
COSTA RICA: Dominical, Puntarenas, 9-XIl-63, 3 m , No. 296, liana, S. L. Wood; Turrialba, Cartago, 14-VIII62, Theobroma cacao, J. L. Saunders: Finca Los Diamantes (Limón?), 7-II-63, Theobroma cacao, J. L. Saunders; Guápiles, Limón, 22-VIII-66, 100 m , No. 120, Cordia, S. L. Wood. PANAMA: Cerro Campana, Cocle, 26-VIII-66, tree branch, S. L. Wood. OTHER AREAS: Venezuela, Brazil.

Hosts.- Cordia sp., Theobroma cacao, etc.
Biology.- Specimens were taken from material $5-15 \mathrm{~cm}$ in diameter.

Notes.- The above treatment was based on the lectotype and on 29 other specimens, several of which were compared directly to the lectotype.

## 23. Xyleborus (Ambrosiodmus?) obliquus (LeConte)

Pityophthorus obliquus LeConte, 1878, in Schwarz, Proc. American Philos. Soc. 17:432 (Holotype, female; Enterprise, Florida; Mus. Comp. Zool., I288)
Ambrosiodmus obliquus: Blackman, 1928, Bull. New York St. Coll. For., Syracuse, Tech. Pub. 25:148
Xyleborus giltipes Blandford, 1898, Biol. Centr. Amer., Coleopt. 4(6):205 (Holotype, female; Zapote, Guatemala; British Mus. Nat. Hist.); Wood, 1975, Great Basin Nat. 35:394. Synonymy

Ambrosiodmus linderae Hopkins, 1915, U.S. Dept. Agric. Rept. 99:56 (Holotype, female; Rosslyn, Virginia; U.S. Nat. Mus., 7418); Bright, 1968, Canadian Ent. 100:1301. Synonymy
Xyleborus brasiliensis Eggers, 1928, Arch. Inst. Biol. 1:96 (Lectotype, female; Blumenau, Santa Catarina, Brazil; U.S. Nat. Mus., 60712, designated by Anderson and Anderson, 1971, Smithsonian Contrib. Zool. 94:7); Wood, 1975, Great Basin Nat. 35:394. Synonymy
Xyleborus mexicamus Eggers, 1931, Ent. Blätt. 27:19 (Holotype, female; Maravatio, presumably Michoacán, Mexico; Zool. Mus. Berlin); Wood, 1972, Great Basin Nat. 32:198. Synonymy
Xyleborus illepidus Schedl, 1941, Rev. Zool. Bot. Afr. 34:402 (Holotype, female; Deutsch-Ostafrika; Schedl Coll.; Wood, 1975, Great Basin Nat. 35:394. Synonymy
Diagnosis.- This species is distinguished from the very similar rubricollis Eichhoff by the smaller average size, by the smaller, confused asperities on the pronotal disc, by the much smaller declivital strial punctures, and by the more broadly convex elytral declivity. However, the antennal club is larger and has two sutures marked on the apical third of the posterior face.

Female.- Length 2.2-2.4 mm, 2.3 times as long as wide; color reddish brown.

Frons and pronotum as in rubricollis except asperities on pronotal disc slightly smaller, confused.

Elytra as in rubricollis except interstrial punctures on disc not granulate, declivity more broadly convex, very weakly impressed on interstriae 2; strial punctures on declivity not larger than on disc; declivital interstriae three times as wide as striae; ventrolateral declivital costa almost smooth.

Male.- Length $1.5 \mathrm{~mm}, 1.4$ times as long as wide; head about as in female except eye reduced; pronotum 0.80 times as long as wide, very weakly convex, devoid of asperities, reticulate, with very obscure punctures; elytra arched from base, striae and interstriae as in female except feebly impressed, declivity evenly convex, devoid of granules; ventrolateral declivital costa absent.

Distribution.-Mississippi and Virginia to Florida and Brazil.

USA: District of Columbia: "DC." Florida: Enterprise, Gainesville, St. John Co., Suwannee Co. Georgia: Millner. Mississippi: Nicholson. Virginia: Falls Church, New Iberia, Rosslyn. MEXICO: Michoacán: Maravatio. GUATEMALA: Zapote. OTHER COUNTRIES: Colombia, Brazil, Congo, Deutsch-Ostafrika (Zambia).

Hosts.- Betula sp., Castenia dentata, Lindera sp., "Ironwood."

Notes.- The above treatment was based on the holotypes of obliquus, gilvipes, linderae, illepidus, and mexicanus, on the lectotype of brasiliensis, and on 138 other specimens. This species has been carried through commerce over a broad area. Although its origin is not known at present, its arrival in Africa apparently is recent.

## 24. Xyleborus (Ambrosiodmus?) devexulus Wood

Xyleborus devexus Wood, 1977 (nec Schedl 1977) Great Basin Nat. 37:219 (Holotype, female; Homestead, Florida; W'ood Coll.)
Xyleborus devexulus Wood, 1978, Great Basin Nat. 38:398. Replacement name
Diagnosis.- This species is distinguished from obliquus (LeConte) by the smaller size, by the coarser, deeper elytral punctures, and by the absence of tubercles on declivital interstriae 1 and 3 .

Female.- Length $1.8-2.1 \mathrm{~mm}, 2.5$ times as long as wide; color very dark brown.

Frons and pronotum as in obliquus.
Elytra as in obliquus except declivity slightly steeper, less strongly convex; punctures on disc larger, deeper, interstriae twice as wide as striae; interstrial punctures near declivity not granulate. Declivity more distinctly impressed between interstriae 3, interstriae 1-3 without granules. Vestiture as in obliquus.
Distribution.-Florida, Puerto Rico.
USA: Florida: Homestead, Lake Co., Manatee Co., Orange Co., Orange Heights, Pinellas Co. PUERTO RICO: Vega Alta, Río Grande.

Hosts.- Carya sp., Cedrella mexicana.
Notes.- The above treatment was based on 31 specimens.

## 25. Xyleborus (Ambrosiodmus) devexus Schedl

Xyleborus devexus Schedl, 1977, Zeitschr. Arb. Österr. Ent. 29:45 (Holotype, female; Metapán, El Salvador; Schedl Coll.)
Diagnosis.- This species is distinguished from rusticus Wood by characters summarized in the above key.

Female.- Length $2.7 \mathrm{~mm}, 2.5$ times as long as wide; color very dark brown.

As in rusticus except punctures on discal interstriae finer, not as deep, interstriae three to four times as wide as interstriae, declivity shallowly bisulcate, with its punctures fine, granules present only on basal half.

Distribution.-El Salvador.
EL SALVADOR: Metapán. 20-X1I-1974, 1600-2200 m, Quercus, H. Schmutzenhofer.
Notes. - The above treatment was based on the holotype.

## 26. Xyleborus (Ambrosiodmus) scalaris Schedl

Nyleborus scalaris Schedl, 1935, Archiv. Inst. Biol. Veget. Río de Janerro 2:95 (Holotype, female; Turrialba, Cartago. Costa Rica; Schedl Coll.)
Diagnosis.- Among the American Ambrosiodmus this species is distinguished by the feebly asperate posterior third of the pronotum, by the evenly convex elytral declivity with all interstriae equally granulate, and by the uniformly short elytral vestiture.

Female.- Length $4.0-4.3 \mathrm{~mm}, 2.3$ times as long as wide; color reddish brown.

Frons as in rusticus Wood except more strongly reticulate, all punctures obscure.
Pronotum 1.1 times as long as wide; sides almost straight and parallel on basal half, rather broadly rounded anteriorly; summit distinctly behind middle; rather finely, closely asperate on anterior half, asperities gradually decreasing in size posteriorly to base, minute on basal third; surface between asperities minutely reticulate. Vestiture hairlike, largely confined to marginal areas.

Elytra 1.4 times as long as wide, 1.4 times as long as pronotum; outline and disc as in rusticus except interstrial punctures not granulate. Declivity more broadly convex and not quite as steep as in rusticus; strial punctures twice as wide as on disc; interstriae one and one-half times as wide as striae, granules rather small, of equal size on all interstriae, mostly confused toward base, uniseriate on lower half. Vestiture of moderately coarse, interstrial hair of uniform length on disc and declivity, each seta about two-thirds as long as distance between rows on declivity; strial setae minute.

Distribution.- Costa Rica.
COSTA RICA: Moravia, Cartago, 11-111-64, 500 m , No. 491, log, S. L. Wood; Turrialba, Cartago, Schild.

Biology.- The Moravia specimen was taken from a new tunnel in a $\log 90 \mathrm{~cm}$ in diameter.

Notes.- The above treatment was based on my female homotype that was compared by me directly to the holotype.

## 27. Xyleborus (Ambrosiodmus) rusticus Wood

Xyleborus rusticus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):36 (Holotype, female; 10 km NE Teziutlan, Puebla, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from rubricollis Eichhoff by the larger size, by the proportionately smaller punctures on the declivital striae, and by the uniformly convex elytral striae.

Female.- Length $3.3-3.5 \mathrm{~mm}, 2.3$ times as long as wide; color dark brown.

Frons broadly, irregularly convex; surface reticulate, shining, punctures rather coarse, close, moderately deep above, obscure below; vestiture sparse, inconspicuous.

Pronotum 0.98 times as long as wide; subcircular, all margins about equally arcuate, widest slightiy behind middle; summit distinctly behind middle; entire surface closely, rather coarsely asperate to base, slightly finer on posterior third; surface between asperities reticulate, dull. Vestiture of fine, rather long, moderately abundant hair.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; sides straight on basal two-thirds, slightly wider at base of declivity, broadly rounded behind; dise occupying basal two-thirds; striae 1 feebly, others not impressed, punctures rather small, moderately deep, spaced within row by one to two diameters of a puncture; interstriae about four times as wide as striae, almost smooth, shining, punctures small, moderately confused, their anterior margins finely granulate. Declivity steep, evenly, broadly convex; strial punctures slightly wider than on dise; interstriae three times as wide as striae, granules on all interstriae distinctly larger, pointed. Vestiture of short strial hair and fine, long, abundant interstrial hair; interstrial setae in almost uniseriate rows on declivital interstriae 1 and 2, confused elsewhere.

Distribution.- Puebla to Chiapas.

MEXICO: Chiapas: 8 km SW El Bosque, 3-VII-69, Pinus, D. E. Bright; 32 km N Bochil, 10-VI-69, D. E. Bright. Puebla: 10 km NE Teziutlan, 27-VI-53, No. 49, $\log$, and 2-VII-67, 1600 m , No. 150, log, S. L. Wood.

Biology. - Both specimens were taken from new tunnels in logs about 30 cm in diameter.

Notes. - The above treatment was based on the two females in the type series and on one other specimen.

## 28. Xyleborus (Ambrosiodmus) rubricollis Eichhoff

Xyleborus rubricollis Eichhoff, 1875, Ann. Soc. Ent. Belgique I8:202 (Holotype, female; Japan; presumably in Brussels Mus.); Bright, I968, Canadian Ent. 100: 1302 (First American record).
Diagnosis.- This species is distinguished from rusticus Wood by the smaller size, by the moderately impressed declivital striae 1 , by the proportionately larger strial punctures on the declivity, and by the distribution.

Female.- Length 2.4-2.6 mm, 2.4 times as long as wide; color reddish brown.

Frons as in rusticus.
Pronotum 1.0 times as long as wide; slightly more nearly quadrate than rusticus, anterior asperities distinctly larger, asperities posterior to summit somewhat oriented to form low, continuous, transverse ridges.

Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; outline as in rusticus; striae 1 feebly, others not impressed, punctures rather coarse, moderately deep; interstriae smooth, shining, twice as wide as striae, punctures small, shallow, moderately confused on 2 , uniseriate on 1 to 9 , minutely granulate. Declivity rather steep, broadly convex; striae 1 weakly impressed, punctures one and one-half to two times as large as those on disc; interstriae 1 to 7 uniseriately granulate, granules pointed, somewhat irregular in size, 8 subacutely elevated, obscurely serrate. Vestiture of rows of fine, long, interstrial hair, and minute strial setae.

Distribution.- Connecticut to Alabama; Japan and Malaya.

USA: Alabama: Corona Mine, 6-VIII-76, B. A. Hawkins. Comnecticut: Norwalk, 9-VIII-70, dogwood, R. H. Perry. Florida: Ocala, 11-IX-77. Maryland: Ridgely, 15-IX-42, oak stump, W. H. Anderson. Pennsylvania: Delaware Co., 7-VIII-80, Carya glabrata, G. Stevens. Tennessee: Nashville, 23-IX-80, Juglans nigra, B. C. Weber. Virginia: Chesapeake, 16-V-70, pecan trunk, M. A. Smith.

Biology.- The American series were taken from boles and stumps of trees. In Japan it has been taken from many hosts, including Acacia, Castanea, Carya, Ilex, Hovea, Lygustrum, Machilus, Morus, Myrica, and Rhus. American records add Carya, Cornus, Prunus, and Quercus.

Notes. - The above treatment was based on 44 American specimens, more than 100 from Japan, and one from Malaya.

## 29. Xyleborus (Ambrosiodmus) opimus Wood

Xylehorus opimus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):37 (Holotype, female; Sebring, Florida, Wood Coll.)
Diagnosis.- This species is distinguished from lecontei (Hopkins) by the slightly smaller size, by the more strongly arcuate anterior and lateral margins of the pronotum, by the finer, less numerous asperities on the pronotal disc, by the convex elytral declivity, and by the different arrangement of declivital tubercles.
Female.- Length $2.4 \mathrm{~mm}, 2.2$ times as long as wide; color reddish brown.

Frons as in lecontei. Pronotum 1.0 times as long as wide, as in lecontei except anterior and lateral margins more strongly arcuate, summit slightly higher, and asperities behind summit slightly smaller and evidently less numerous.

Elytra 1.36 times as long as wide; outline and disc as in lecontei except strial punctures not larger near declivity, interstrial punctures near declivity granulate. Declivity rather broadly, evenly convex, steep; strial punctures as large as on disc, deep, smaller than in lecontei; interstriae 1 bearing a row of granules on basal half, those near base rather coarse, 2 with several pointed tubercles on basal half, one or two at or slightly below middle distinctly larger, 3 with thre to five smaller tubercles; all tubercles smal er than major tubercles of lecontei. Vestiture as in lecontei.

Distribution.- Florida.
USA: Florida: Sebring, 20-V1-51, at light, S. L. W1 od.
Notes.- The above treatment was based on the unique female holotype.

## 30. Xyleborus (Ambrosiodmus) lecontci (Hopkins)

Ambrosiodmus lecontei Hopkins, 1915, U.S. Dept. Agric. Rept. 99:56 (Holotype, female: Keene, Florida; U.S. Nat. Mus., 7+19)

Nyleborus gundlachi Eggers, 1931, Ent. Blätt. 27:20 (Holotype, female: Cuba: Zool. Mus. Berlin); Wood, 1972, Great Basin Nat. 32:199. Synonymy
Diagnosis.- This species is distinguished from opimus Wood as indicated in the above key and in the diagnosis of opimus.

Female.- Length 2.5-3.0 mm, 2.3 times as long as wide; color rather dark reddish brown.

Frons broadly, irregularly convex, shining, with some indications of reticulation, punctures coarse, deep, close, obscure on lower half; vestiture sparse, inconspicuous.

Pronotum 1.0 times as long as wide, obscurely subquadrate, anterior and lateral margins rather weakly arcuate; summit broadly rounded, slightly behind middle; asperities continued to base, those behind summit moderately coarse, confused; surface of disc between asperities reticulate. Vestiture of fine, moderately long hair.

Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; sides straight on basal three-fourths, slightly wider at base of declivity, broadly rounded behind and with declivital denticles projecting; striae not impressed, punctures coarse, deep, close, about twice as long near declivity as at base; interstriae almost smooth, shining, as wide as striae near declivity, twice as wide at base, punctures small, shallow, uniseriate except slightly confused on 2. Declivity broadly convex, shallowly impressed between interstriae 3 , steep; interstriae 1 unarmed, punctured, impressed, 2 ascending toward 3 , armed by two or three coarse, pointed denticles on middle twothirds, 3 broadly rounded, armed by one to three smaller denticles, 4,5 , and 6 with a few smaller granules, 7 subacutely elevated to apex, its crest almost smooth. Vestiture of fine, moderately long rather abundant hair.

Male.- Length 1.4 mm ; as in male obliquus except pronotum with a few minute asperities and elytral punctures coarse, moderately deep, strial and interstrial punctures almost equal in size; declivital interstriae each with three or four granules, those on 2 slightly larger.

Distribution.-Florida and Louisiana to Puerto Rico.

USA: Florida: Bevard Co., Biscayne Bay, Brookville, Everglades N.P., Gulfport, Hillsboro, Homestead, Indian River, Key Largo, Key West, Lake Worth, Marion Co., Miami, Oceola Co., Orange Co., Orlando, Pinellas Co., Plant City, Seminole. Louisiana: "Delta area." OTHER AREAS: Cuba, Dominican Republic, Puerto Rico.

Hosts.- Bishofia javanica, Carya sp., Dacryodes sp., Diphysia robinoides, Ichthyomethia communis, Persea borbonea, Pinus occidentalis, Pleiogynum sp., Terminalia sp.

Biology.- Specimens were taken at ground level from stems $3-5 \mathrm{~cm}$ in diameter and from tree branches of similar diameter. The main adult gallery consists of a radial entrance tumnel and a transverse biramous gallery that follows a growth ring, in both directions, thus forming an almost complete ring around the stem about 1 cm below the surface of the wood.

Notes.- The above treatment was based on the holotype and on 74 other specimens.

## 31. Xyleborus (Ambrosiodmus) guatemalensis (Hopkins)

Ambrosiodmus guatemalensis Hophins, 1915, U.S. Dept. Agric. Rept. 99:56 (Holotype, female; Trece Aguas, Alta Verapaz, Guatemala; U.S. Nat. Mus. 7652)

Xyleborus anisandrus Schedl. 1954, Dusenia 5:44 (Syntypes, female; Río Claro, Brazil: Schedl Coll.); Wood, 1972, Great Basin Nat. 32:198. Synonymy
Diagnosts.- This species is distinguished from lecontei Hopkins by the much finer punctures on the elytra, by the less strongly arched elytral declivity, and by the smaller denticles on the declivity.

Female.- Length $2.4-2.8 \mathrm{~mm}, 2.3$ times as long as wide; color reddish brown.

Frons and pronotum essentially as in lecontei.

Elytral proportions and outline as in lecontei; striae not impressed, punctures small, shallow; interstriae smooth, shining, three times as wide as striae, punctures usually distinctly smaller than those of striae, uniseriate. Declivity moderately steep, broadly convex, and shallowly sulcate between interstriae 3; sutural interstriae feebly elevated, unarmed (an occasional minute granule sometimes present); rather broadly, shallowly impressed in area of striae 2 ; interstriae 2 moderately ascending, armed by two or three denticles
similar to but smaller than in lecontei, 3 broadly rounded, with one or two smaller denticles; lateral areas with a few scattered granules; strial and interstrial punctures shallow, similar to those on disc; interstriae 7 subacutely elevated to apex. Vestiture of fine, rather abundant hair of moderate length; strial setae almost as long as those of interstriae.

Distribution.- Oaxaca and Veracruz to Brazil.

MEXICO: Oaxaca: Oaxaca. Veracruz: 37 and 29 km N Matías Romero. GUATEMALA: Trece Aguas in Alta Verapaz. HONDURAS: Zamorano. COSTA RICA: Guápiles in Limón, Playón and Santa Ana in San José. PANAMA: EI Hato del Volcán in Chiriqui. OTHER COUNTRIES: Brazil, Colombia, Venezuela.

Hosts.- Cedrella mexicana, Mar gifera indica, Ochroma sp., Terminalia sp., Theobroma сасао.

Biology.- As in lecontei except all specimens were taken from limbs and branches or the bole of trees 3-5 cm in diameter.

Notes.- The above treatment was based on the holotype of guatemalensis, on my homotype of anisandrus that was compared directly to Schedl's syntypes, and on 26 other specimens.

## 32. Xyleborus (Ambrosiodmus) tachygraphus Zimmermann

Xyleborus tachygraphus Zimmermann, 1868, Trans. American Ent. Soc. 2:144 (Holotype, female; square tan tag signifying southern states, published as North Carolina, Mus. Comp. Zool., 990)
Diagnosis.- This species is almost indistinguishable from coffeiceus Schedl (from Surinam); it is very slightly larger, the interstrial punctures on the disc are less distinctly impressed, and the sutural interstriae on the declivity are slightly narrower, not elevated, and have their surface less smooth.

Female.- Length $3.4-3.8 \mathrm{~mm}, 2.3$ times as long as wide; color dark reddish brown to almost black.

Frons and pronotum essentially as in lecontei (Hopkins), except pronotum slightly narrower anteriorly.

Elytra 1.5 times as long as wide, 1.5 times as long as pronotum; outline as in obliquus; striae not impressed, punctures small, shallow, distinct; interstriae four times as wide as striae, shining, minutely, rather obscurely
subrugose, punctures small, obscure, uniseriate except confused on 2. Declivity broadly convex, steep; interstriae 1 flat, its surface irregular, usually marked by obscure, irregular lines, 2 ascending slightly and armed on middle half by two widely spaced, rather coarse, pointed denticles, 3 not higher than 2, broadly rounded, armed by about one to three smaller denticles, lateral areas with a few minute granules, 7 subacutely elevated to apex. Vestiture of moderately abundant, fine, long hair.
Distribution.- Illinois and Pennsylvania to Alabama and Georgia.

USA: Alabama: Mobile. District of Columbia: Washington. Georgia: Macon. Illinois: Pine Hills Field Station in Union Co. Maryland: Bell, Bowie, Plummer's Island. New Jersey: Anglesia. North Carolina: Black Mtn., Cedar Mitn., Chadbourn, Durham, Southern Pines, Tryon. Pennsylvania: Castle Rock. South Carolina: Holly Hill, Myrtle Beach. Virginia: Falls Church, Ft. Monroe, Rosslyn, Vienna. West Virginia: Dellslow.
Hosts.- Betula sp., Carya sp., Castanea dentata, Juglans sp., Rhus sp.

Biology.- As in lecontei.
Notes.- The above treatment was based on the holotype and on 104 other specimens.

## 33. Xyleborus (Ambrosiodmus) rugicollis Blandford

Xylcborns rugicollis Blandford, I898, Biol. Centr. Amer., Coleopt. 4(6):207 (Holotype, female; Cerro Zunil. Quezaltenango, Guatemala; British Mus. Nat. Ifist.)
Diagnosis.- This species is distinguished from tachygraphus Zimmermann by the larger size, by the slightly larger and deeper elytral punctures, and by the slightly larger minor granules on the elytral declivity.

Female.- Length $4.9 \mathrm{~mm}, 2.6$ times as long as wide; color black.

As in tachygraplius except for the larger size and coarser elytral sculpture.

Distribution.-Guatemala.
GUATEMALA: Cerro Zunil, Quezaltenango, $4000-5000 \mathrm{ft}, \mathrm{G}$. C. Champion.

Notes.- The above treatment was based on the unique holotype.

34a. Xyleborus fornicatus Eichhoff

Xylchorus fornicatus Eichhoff, I868, Berliner Ent. Zeitschr. 12:151 (Syntypes: Ceylon; not located)

Xyleborus fornicatior Eggers, 1923, Zool. Meded. 7:184 (Syntypes; Peradeniya, Ceylon; Hamburg Mus. and Eggers Coll.): Beeson, 1930, Indian For. Rec. 14:59. Varicty
Diagnosis. - The contiguous procoxae and one suture on the posterior face of the antennal club distinguish this from most species; from validus Eichhoff it is distinguished by the smaller size and by the more strongly procurved, more strongly serrate anterior margin of the pronotum.

Female.- Length 1.9-2.5 mm, 2.3 times as long as wide; color dark brown to almost black.

Head and outline of pronotum about as in obliquus (LeConte).

Pronotum as long as wide; sides on basal half weakly arcuate, subparallel, semicircularly rounded in front; anterior margin armed by eight or more rather coarse serrations; summit slightly behind middle; surface (except asperities) reticulate; rather coarsely asperate in front of summit, smooth behind, except for reticulation, punctures rather sparse, fine, but irregular in size. Hairlike vestiture limited to sides and asperate area.

Elytra 1.2 times as long as wide, 1.3 times as long as pronotum; sides almost straight and subparallel on basal two-thirds, broadly rounded behind; striae not impressed, punctures rather fine, distinct, shining; interstriae three to four times as wide as striae, smooth, shining, punctures uniseriate, fine, most of them at least finely granulate except at base. Declivity commencing at middle, broadly, evenly arched; subapical margin narrowly costate from apex to interstriae 7; striae not noticeably curved toward suture, very feebly impressed; sculpture about as on disc except interstrial granules slightly larger. Vestiture of rows of moderately long interstrial hair, each seta distinctly longer than distance between rows or between setae within a row.

Male.- Length $1.5-1.6 \mathrm{~mm}$; head and elytra somewhat similar to female, pronotum less strongly declivous in front, asperities greatly reduced in size, anterior margin unarmed; declivity occupying two-thirds of elytral length.

Distribution.- Panama, Hawaii to southern Asia, Africa.

PANAMA: Canal Zone, VII-79, tree branch.
Notes.- The above treatment was based on 42 specimens in my collection that agree
with specimens in the Blandford, Eggers, and Schedl collections.

## 34b. Xyleborus validus Eichhoff

Nyleborus validus Eichhoff, 1875, Amn. Soc. Ent. Belgique 18:202 (Syntypes, female: Japan; apparently Brussels Mus.)
Diagnosis. - The presence of a suture on the posterior face of the antennal club, a conspicuous segment 2 on the anterior face, and 12 socketed protibial teeth distinguish this introduced species from native American species. From fornicatus Eichhoff it is distinguished by the larger size and by the more nearly quadrate pronotum, with the serrations on the anterior margin absent or greatly reduced.

Female.- Length $3.4-3.8 \mathrm{~mm}, 2.4$ times as long as wide; color dark brown to almost black.

Head and pronotum about as in fornicatus except anterior margin of pronotum much more broadly rounded, serrations reduced to almost absent, sides less strongly arcuate.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on more than basal two-thirds, rather broadly rounded behind; striae weakly impressed, punctures rather small, distinctly impressed; interstriae two to three times as wide as striae, smooth, brightly shining, small, uniseriate punctures replaced by fine granules except at base. Declivity moderately steep, very broadly convex, sutural profile feebly convex; striae on apical fourth curved toward suture; strial punctures distinctly larger than on disc except near apex; sculpture about as on disc except tubercles distinctly larger; tubercles on lower half of interstriae 2 usually obsolete.

Male.- Length 2.3 mm ; basically similar to female except pronotal asperities greatly reduced, anterior margin unarmed; declivity commencing anterior to middle; all features less perfectly formed.

Distribution.-New York to Pennsylvania, northern Japan.

USA: New York: Old Westway, Nassau Co., 12-V1976, Fagus. Pennsylvania: Newton Square, Delaware Co., 2-VII-80, Quercus velutina, G. Stevens.

Biology.- In Japan it breeds in logs, stumps, and unthrifty material larger than 8 cm in diameter from 14 broadleaf host
genera as well as Abies and Picea. In southern Japan and throughout southeast Asia to Sri Lanka, it is replaced by the superficially similar interjectus Blandford, with which it is easily confused.

Notes. - The above treatment was based on the holotype and 67 other specimens from Japan and on 6 from the United States.

## 34c. Xyleborus spathipennis Eichhoff Fig. 184

Xyleborus spathipennis Eichhoff, 1868, Berliner Ent. Zeitschr. 12:145 (Syntypes, female; Peru and Brazil; lost with Hamburg Mus.)
Xyleborus coronatus Eichhoff, 1878, Mém. Soc. Roy. Sci. Liége (2)8:348 (Holotype, male; Brasilia interior: Brussels Mus.); Wood, 1972, Great Basin Nat. 32:199. Synonymy
Boroxylon burgdorfi Hopkins, 1915, U.S. Dept. Agric. Rept. 99:59 (Holotype, female; Costa Rica; U.S. Nat. Mus., 7653); Wood, 1972, Great Basin Nat. 32:199. Synonymy
Xeyleborus curtus Eggers, 1928, Archiv. lnst. Biol. São Paulo 1:94 (Lectotype, female; Cachabé, Equador; U.S. Nat. Mus., 60694, subsequent designation by Anderson and Anderson, 1971, Smithsonian Contrib. Zool. 94:11); Wood, 1972, Great Basin Nat. 32:199. Synonymy
Xyleborus femoratus Eggers, 1928, Archiv. Inst. Biol. São Paulo 1:95 (Lectotype, female; Bahia, Brazil; Berlin Mus., present designation); Schedl, 1960, Coleopt. Bull. 14:12. Synonymy
Diagnosis.- This species is distinguished from princeps Blandford by the smaller size, by the stouter body, by the irregularly serrate anterior margin of the pronotum, and by the equal development of small granules on all declivital interstriae.

Female.- Length 4.4-5.3 mm, 2.2 times as long as wide; color dark brown to black.

Frons weakly convex, with median line weakly elevated; surface reticulate, subshining, coarsely punctured, closely above, sparsely below; vestiture sparse, hairlike.

Pronotum 1.0 times as long as wide; sides weakly arcuate and subparallel on slightly more than basal half, rather broadly rounded in front; anterior margin irregularly serrate; summit slightly behind middle; anterior slope rather coarsely asperate; posterior areas smooth to weakly reticulate, punctures fine, deep, rather close. Vestiture confined to margins, sparse.

Elytra 1.2 times as long as wide, 1.3-1.5 times as long as pronotum; disc occupying basal half; sides weakly arcuate, widest slightly behind middle, broadly rounded
behind; striae sinuate, narrowly impressed, punctures small, rather shallow, very close; interstriae 1 narrow at base, becoming twice as wide at base of declivity, 2 and 3 similarly but less strongly narrowed toward base, surface smooth and shining, punctures very fine, confused, those few bearing setae larger and on 1 and 2 these punctures weakly granulate. Declivity gradual, broadly convex except a broad, weak, transverse impression on lower fourth; surface dull; all striae curve strongly toward sutural apex on apical fourth; all interstrial punctures minute granulate, setiferous granules on odd-numbered interstriae distinctly larger. Vestiture of sparse, widely spaced interstrial bristles mostly on odd-numbered interstriae; minute granules usually bearing minute, very short, hairlike setae on younger specimens.

Male.- Length $4.0-5.0 \mathrm{~mm}$; head somewhat similar to female except with a conspicuous, wide, median sulcus, and eye reduced; elytra essentially as in female; pronotum 1.3 times as long as wide, slightly wider than elytra, its sides straight and parallel on basal nine-tenths; slightly less than anterior half very deeply, broadly, concavely excavated, anterolateral angles strongly produced into lateral lobes, median third of anterior margin strongly produced into a blunt process; anterior areas devoid of asperities.

Distribution.- Nicaragua to Bolivia and Brazil.

NICARAGUA: Intercepted from Nicaraguan mahogany, 9-IX-38. COSTA RICA: Rincón de Osa, Puntarenas, 11-VIII-66, 30 m , No. 3 in Euphorbiaceae log, No. 51 in Bursera simarubra $\log$, S. L. Wood; Finca Gromaco on Río Coto Brus, Puntarenas, I4-V1I-63, 500 m , No. 79 , palm log, S. L. Wood; Río Damitas, Dota Mts., San José, 22-VIII-63, 250 m , No. I23, log, S. L. Wood; Hamburgfarm on Río Reventazón, Limón, 26-V-35, F. Nevermann. OTHER COUNTRIES: Colombia, Venezuela, British Guiana, Equador, Peru, Bolivia, Brazil.

Hosts. - Numerous tree species.
Biology.- This species occurs in wet lowland forests in almost any souring log that is in contact with the soil. The elongate gallery system branches and rebranches and anastomoses with other systems. Few other Scolytidae tolerate the wet souring conditions where this species breeds.

Notes. - The above treatment was based on the holotypes of coronatus and burgdorfi, on the lectotypes of curtus and femoratus, on the Chapuis "syntypes" of spathipennis, and on 74 other specimens.

Five females from Cayenne, in the Chapuis Collection, bear the determination label of Eichhoff and a type label. Nevertheless, because they do not come from either Peru or Brazil, they cannot be syntypes. If authentic syntypes cannot be found, the first Chapuis specimen in this series should be designated as the neotype because it was determined by Eichhoff. The first of three syntypes in the Berlin Museum is designated as the lectotype of femoratus.

Fig. 184. Xyleborus spathipennis: a, Male; b, female; c, female declivity, setae omitted.
35. Xyleborus princeps Blandford Fig. 185

Xyleborus princeps Blandford, 1898, Biol. Centr. Amer., Coleopt. 4(6):208 (Lectotype, female; Volcán Chiriquí, Chiriquí, Panama; British Mus. Nat. Hist., present designation)
Xyleborus spathipennis var. ohausi Hagedorn. 1912. Rev. Zool. Afr. 1:345 (Syntypes; Pucay, Equador; lost with Hamburg Mus.); Eggers, 1933. Ent. Nachrbl. 7:20. Synonymy
Diagnosis.- This is the largest known American Xyleborus. It is distinguished from spathipennis Eichhoff as indicated in the above key and in the diagnosis of spathipennis.

Female.- Length 5.1-5.9 mm, 2.5 times as long as wide; color very dark brown to almost black.

Frons and pronotum as in spathipennis except pronotum more nearly quadrate, 1.0 times as long as wide, anterior margin much more broadly rounded and feebly, if at all, serrate.

Elytra 1.7 times as long as wide, 1.8 times as long as pronotum; sides straight on basal two-thirds, widest two-thirds elytral length from base, rather narrowly rounded behind; discal sculpture restricted to basal third of elytral length; elytral sculpture as in spathipennis except declivity more gradual but transversely more narrowly convex, particularly on apical third, strial punctures on declivity slightly larger, and setiferous declivital granules distinctly larger.

Distribution.- Nicaragua to Ecuador.
NICARAGUA: Chontales, Janson. COSTA RICA: Río Negro, 25 km NE La Union, Puntarenas, 20-11-65, log, J. B. Karren; Tapantí, Cartago, 17-1X-6.3, 1300 m , No. 179. log, S. L. Wood. Panania: Volcán de Chiriquí, G. C. Champion. OTHER COUNTRIES: Colombia, Ecuador.

Biology.- Evidently as in spathipennis, but much less common.

Notes.- The above treatment was based on Blandford's three female syntypes, and on eight other specimens. The first syntype in the series from Volcán Chiriquí, Panama, is here designated as the lectotype of princeps Blandford.

## 36. Xyleborus asper Eggers

Fig. 185

Xylchorus asper Eggers, 1933, Trav. Lab. Ent. Mus. Nat. Hist. Nat., Mém. 1(1):30 (Holotype, female; Nouveau Chantier; Paris Mus.)

Xyleborus amoenus Schedl, 1949, Rev. Brasil. Biol. 9:282 (Holotype, female; Hamburgfarm on Río Reventazón, Limón, Costa Rica; Schedl Coll.); Wood, 1972, Great Basin Nat. 32:196. Synonymy
Diagnosis. - This species is not closely allied to any other North or Central American species. It is distinguished by the subquadrate pronotum, by the declivital slope and sculpture that commence less than one-third of the elytral length from the base, by the dull declivity, and by the equally granulate declivital interstriae.

Female.- Length $2.7-2.8 \mathrm{~mm}, 2.5$ times as long as wide; very dark brown.

Frons essentially as in spathipennis.
Pronotum 1.08 times as long as wide; subquadrate, anterior and lateral margins weakly arcuate, anterior submargin weakly serrate; summit slightly in front of middle; anterior slope rather coarsely asperate, posterior areas almost smooth, feebly reticulate, punctures minute, sparse. Vestiture confined to margins, sparse.

Elytra 1.4 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal three-fourths, rather narrowly subangulate behind; disc confined to basal third of elytral length; striae not impressed, punctures small, moderately deep, spaced within row by two diameters of a puncture; interstriae smooth, shining, about four times as wide as striae, punctures very small, uniseriate. Declivity commencing onethird elytral length from base, slope gradual on its basal half, steeper behind; surface dull; striae distinctly impressed, punctures rather coarse, close; interstriae smooth, dull, one and one-half to twice as wide as striae, uniseriately granulate; pointed granules variable, small ones bearing a minute, short, hairlike seta, approximately alternating with distinctly larger ones bearing coarse bristles; longest bristles slightly longer than distance between rows, more widely spaced within a row.

Male.- Length $2.1 \mathrm{~mm}, 2.3$ times as long as wide; head and elytra about as in female but with all characters poorly formed; pronotum 1.2 times as long as wide, 1.1 times as long as elytra, with asperities greatly reduced in size and number, slightly more than anterior half shallowly, broadly concave, sides rounded, anterior margin medially produced to a point.

Distribution.- Costa Rica to Colombia and French Guiana.

COSTA RICA: Hamburgfarm on Rio Reventazón, Limón, 23-1II-34. Virola uarburgii; Finca La Lola, Limón, 22-VI-63, Theobroma cacāo, J. L. Saunders: Guápiles, Limón, 22-VIII-66, 100 m , No. 101, tree limb, S. L. Wood. PANAMA: Barro Colorado Island, Canal Zone, 27-NIL-63, 70 m , No. 351 in tree branch, also in a $\log$, S. L. Wood. OTHER COUNTRIES: Colombia. Venezuela, French Guiana.

Hosts.- Couma macrocarpa (Colombia), Pithacellobium pinnatum (Venezuela), Theobroma cacao, Toulicia pulvinata (Venezuela), Virola warburgii, etc.

Biology. - This species breeds in the larger branches, limbs, and bole of a wide variety of hosts.

Notes. - The above treatment was based on the holotype of asper, on my homotypes of amoenus that were compared by me directly to the type, and on 37 other specimens.

## 37. Xyleborus caraibicus Eggers

Xyleborus caraibicus Eggers, 1941, Arb. Morph. Taxon. Ent. Berlin-Dahlem 8:103 (Holotype, female: Guadeloupe; U.S. Nat. Mus., 60681)
Xy/chorus trinidadensis Schedl, 1961. Ann. Mag. Nat. Hist. (I3)3:530 (Holotype, female; River Estate,

Trinidad; British Mus. Nat. Hist.); Wood, 1972, Great Basin Nat. 32:197. Synonymy
Diagnosis.- This species is distinguished from commixtus Blandford by the more strongly, more narrowly convex elytral declivity, with the ventrolateral margin more obtusely elevated, and by the more strongly impressed discal striae.

Female.- Length $3.2-4.1 \mathrm{~mm}, 2.5$ times as long as wide; color dark brown to almost black.

Frons broadly convex, broad median line weakly elevated; surface reticulate, with rather coarse, obscurely impressed punctures.

Pronotum 1.05 times as long as wide; subquadrate, margins rather weakly arcuate; summit at middle; moderately asperate on anterior slope; posterior areas almost smooth, punctures minute, obscure, sparse. Glabrous except for a few hairlike setae at margins.

Elytra 1.6 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae weakly impressed, punctures rather coarse, shallow; interstriae two and one-half times as wide as striae, weakly convex, almost smooth, punctures very fine, shallow, almost uniseriate.

Fig. 185. Xyleborus spp., female declivities with setae omitted: a princeps; b, commixtus; c, asper.

Declivity steep, rather broadly convex; striae 1 more distinctly impressed on middle half; strial punctures about as on disc, becoming smaller on apical fifth; apical fifth near suture slightly inflated; interstriae shining to slightly dull in some specimens, each armed by a uniseriate row of granules, minute and moderately coarse granules mixed in a row; ventrolateral margin obtusely elevated, median side of this elevation flat, not concave. Vestiture confined to declivity, of interstrial bristles mostly two-thirds as long as distance between rows, more widely spaced within a row.
Distribution.- Costa Rica to Brazil.
COSTA RICA: Turrialba, Cartago, 18-IV-63, Theobroma cacao, J. L. Saunders; Rincon de Osa, Puntarenas, 1I-VIII-66, 30 m , No. 55, Ochroma, S. L. Wood; Pandora, Limón, 23-VII1-63, 50 m , No. 135, log, S. L. Wood; Guapiles, Limón, 22-V1II-66, 100 m , No. 102, log, S. L. Wood. PANAMA: Barro Colorado Island, Canal Zone, 27-XII-63, 70 m , No. 335, tree branch, S. L. Wood; Limón Bay, Canal Zone, 30-XII-63, 3 m , No. 351, tree branch, S. L. Wood. OTHER COUNTRIES: Colombia, Venezuela, Trinidad, Brazil, Guadeloupe.

Hosts.- Ochroma sp., Theobroma cacao, etc.

Biology.- This species breeds in the bole, limbs, and larger branches of trees in wet, tropical, lowland areas.

Notes. - The above treatment was based on the holotypes of caraibicus and trinidadensis and on 24 other specimens. The Costa Rican specimens tend to have the declivital striae less strongly impressed and the granules slightly smaller; however, the differences are so slight and inconsistent they are considered to be minor variations within the population.

## 38. Xyleborus commixtus Blandford

 Fig. 185Xyleborus commixtus Blandford, 1898, Biol. Centr. Amer., Coleopt. 4(6):208 (Lectotype, female, Bugaba, Chiriquí, Panama; British Mus. Nat. Hist.. present designation).
Diagnosis.- This species is distinguished from caraibicus Eggers by the larger average size, by the more gradual, more broadly convex elytral declivity, with the posterolateral margin more strongly, more acutely elevated, a slight concavity between its crest and the remainder of the declivity.

Female. - Length $3.7-4.0 \mathrm{~mm}, 2.5$ times as long as wide; color dark brown.

Frons and pronotum essentially as in $c a$ raibicus except pronotal disc and sides reticulate.

Elytral outline and disc as in caraibicus except striae not impressed, punctures smaller, interstriae three to four times as wide as striae. Declivity not as steep as in caraibicus, more broadly convex, suture on lower half straight; striae not impressed, punctures larger ( 1.5 times) than on disc; sutural interstriae slightly impressed on basal half; interstrial granules similar to caraibicus but averaging slightly smaller; ventrolateral margin rather strongly, acutely elevated, distinctly concave between its crest and remainder of declivity, more conspicuous laterally. Vestiture confined to declivity, of slender interstrial bristles, each bristle about one and onehalf times as long as distance between rows, spaced within a row by length of a bristle.

Distribution.- Costa Rica to Panama.
COSTA RICA: Rincón de Osa, Puntarenas, Il-VIII66.30 m . No. 52 in a $\log$, and No. 53 in Pouteria, S. L. Wood. PANAMA: Bugaba, Chiriquí, G. C. Champion.

Hosts.- Pouteria sp., etc.
Biology. - Specimens were taken from logs 35 cm in diameter.

Notes.- The above treatment was based on Blandford's two syntypes and on four other specimens. The first syntype, from Bugaba, Panama, has long been regarded as the type, although it has not been so designated. I here designate it as the lectotype of commixtus Blandford.

## 39. Xyleborus lacunatus Wood

Xyleborus lacunatus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):37 (Holotype, female; Turrialba, Cartago, Costa Rica, Wood Coll.)
Diagnosis.- This species is distinguished from commixtus Blandford by details in sculpture of the elytral declivity as indicated in the description.

Female.- Length $4.0 \mathrm{~mm}, 2.5$ times as long as wide; color dark brown.

Frons, pronotum, and elytral disc as in commixtus. Elytral declivity essentially as in commixtus except rather strongly, transversely impressed on lower third; suture distinctly concave on lower two-thirds; strial punctures larger; interstriae about twice as wide as striae; posterolateral margin much more strongly, acutely elevated than in
commixtus, rather strongly concave from its crest to suture on lower third of declivity. Vestiture as in commixtus.

Distribution.- Costa Rica.
COSTA RICA: Turrialba, Cartago, 18-IV-63, Theobroma cacao, J. L. Saunders; Peralta, Cartago, 10-1I1-64, 500 m . flight, S. L. Wood.

Host.- Theobroma cacao.
Notes.- The above treatment was based on the female holotype and on one other specimen.

## 40. Xyleborus politus Hagedorn

Xyleborus politus Hagedorn, 1905, Bull. Mus. d'Hist. Nat. 6:413 (Lectotype, female; Placêrs du Carsevenne, French Guiana; Paris Mus., present designation)
Diagnosis.- This species is distinguished from mutabilis Schedl by the smaller size, by the smaller strial punctures, particularly on the declivity, by the narrower declivity, which is transversely convex, by the smaller, more numerous declivital granules, and by the more abrupt posterolateral margin of the declivity.

Female.- Length $3.2-3.6 \mathrm{~mm}, 2.6$ times as long as wide; color dark brown.

Frons and pronotum as in caraibicus Eggers.

Elytra 1.7 times as long as wide, 1.7 times as long as pronotum; outline as in mutabilis except more narrowly rounded behind; striae feebly if at all impressed, punctures and interstriae as in caraibicus. Declivity rather steep, transversely rather broadly convex on median half; suture straight on lower half; striae not impressed, punctures rather large, shallow; interstriae slightly more than twice as wide as striae, smooth, shining, part of 2 feebly impressed near middle, granules rather small, pointed, irregular in size, about 12-15 on each interstriae; posterolateral margin obtusely subangulate, armed by several moderately coarse granules. Vestiture largely confined to declivity, of stout interstrial bristles, each slightly more than half as long as distance between rows, spaced within a row by one to two times length of a bristle.

Distribution.- Costa Rica to Venezuela and French Guiana.

COSTA RICA: Rincón de Osa, Puntarenas 11-VII-66, 30 m , Nos. 52 and 89 in logs, No. 92 in a liana, S. L. Wood; Finca Gromaco on Río Coto Brus, Puntarenas, 14-VII-63, 500 m , No. 88, stump, S. L. Wood, Río

Damitas, Dota Mits., San José, 22-V1Il-63, 250 m , No. 124, stump, S. L. Wood; Guápiles, Limón, 22-V111-66, 100 m , No. 101, tree limb, S. L. Wood. OTHER COUNTRIES: Venezuela.

Biology.- Specimens were taken from several unidentified lianas, limbs, and logs.

Notes. - The above treatment was based on the "type" of politus and on 48 other specimens. The first of two syntypes in the Hagedorn series has been considered the type, although it has never been so designated. I here designate that specimen as the lectotype of politus Hagedorn.

## 41. Xylcborus improvidus Schedl

Xyleborus improvidus Schedl. 1935, Arch. Inst. Biol. Veg. Río de Janeiro 2:92 (Holotype, female; Moritz, 1858, Venezuela; Schedl Coll.)
Xyleborus aclinis Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):38 (Holotype, female; Cerro Punta, Chiriquí. Panama; Wood Coll.); Wood, 1979, Great Basin Nat. 39:136. Synonymy
Diagnosis.- This species is distinguished from mutabilis Schedl by the much smaller size, by the more strongly convex declivity, and by the presence of only one tubercle on declivital interstriae 2.

Female.- Length 3.1-3.3 mm, 2.9 times as long as wide; color dark brown.

Frons and pronotum as in meridensis except pronotum 1.14 times as long as wide.

Elytra 1.8 times as long as wide, 1.6 times as long as pronotum; outline and dise as in meridensis except interstrial punctures more widely spaced. Declivity moderately steep, convex; suture feebly convex on lower half; striae not impressed, punctures little if any larger than on disc; interstriae smooth, shining, 1 and 3 each armed by about three to six pointed granules of variable size, 2 armed by one moderately coarse denticle one-third declivital length from apex, a few small granules in lateral areas; posterolateral margin as in mutabilis, narrowly rounded, its crest armed by several small, isolated granules. Vestiture confined to declivity, sparse, one short bristle arising from posterior basal margin of each granule, each bristle about half as long as width of an interstriae.

Distribution.- Panama to Venezuela.
Panama: Cerro Punta near Volcán de Chiriquí, Chiriquí, 11-I-64, 1800 m , No. 386, tree stump, S. L. Wood.

Biology. - Specimens were taken from a stump 15 m in diameter.

Notes.- The above treatment was based on the type series of four female specimens.

## 42. Xyleborus dissimulatus Wood

Xyleborus dissimulatus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):38 (Holotype, female; Tapantí, Cartago, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from mutabilis by the much smaller size, by the smaller strial punctures, by the much smaller granules on declivital interstriae 2, and by the more subangulate, subserrate posterolateral margin of the declivity. It is distinguished, with difficulty, from posticus Eichhoff by characters summarized in the above key.

Female.- Length 2.2-2.3 mm, 2.6 times as long as wide; color brown.

Frons, pronotum, and elytral dise as in posticus.

Elytra 1.6 times as long as wide, 1.6 times as long as pronotum; disc occupying basal 60 percent of elytral length. Declivity moderately steep, rather broadly convex; strial punctures much larger than on disc, very shallow; interstriae smooth, shining, as wide as striae, each with a sparse row of minute granules, 1 and 3 each with about two distinctly larger granules; posterolateral margin subacute, more continuously subserrate than in posticus. Vestiture largely confined to declivity, of very short, stout, and fine interstrial bristles, each bristle about one-third as long as distance between rows.

Distribution.- Costa Rica.
COSTA RICA: Tapantí, Cartago, 2-VII-63, 1300 m , No. 9, Miconia, 17-IN-63, No. 184, Miconia caudata, No. 178, liana, S. L. Wood.
Hosts.- Miconia caudata, M. sp., liana.
Biology.- Specimens were taken from material $8-10 \mathrm{~cm}$ in diameter.

Notes. - The above treatment was based on the type series of five specimens.

## 43. Xyleborus posticus Eichhoff

Xylcborus posticus Eichhoff, 1869. Berliner Ent. Zeitschr. 12:281 (Holotype, female; Caracas, Venezuela; presumably lost with Hamburg Mus.).
Xylcborus novateutonicus Schedl, 1954, Dusenia 5:47 (Syntypes, females; Nova Teutonia, Santa Catarina, Brazil; Schedl and Plaumann colls.); Schedl, 1962, Ent. Blätt. 58:207. Synonymy
Diagnosis.- This species is distinguished from the very closely allied dissimulatus

Wood by the shorter, steeper, more broadly convex declivity, which is usually dull, by the smaller strial punctures on the declivity, and by the much shorter declivital vestiture.

Female.- Length 2.2-2.5 mm, 2.5 times as long as wide; color dark brown to almost black.

## Frons as in caraibicus Eggers.

Pronotum 1.10 times as long as wide; usually subquadrate, with all margins rather weakly arcuate, some specimens with anterior margin more distinctly arcuate; summit at middle; anterior slope rather coarsely asperate, posterior areas reticulate, punctures minute, shallow, sparse. Vestiture confined to margins.

Elytra 1.6 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal three-fourths, then rather abruptly rounded, obtusely subangulate behind; striae not impressed, punctures moderately large, shallow; interstriae three times as wide as striae, subshining, smooth, punctures uniseriate, rather small (sometimes irregular in size). Declivity occupying posterior 25 percent of elytral length, steep, broadly convex; surface dull (less commonly shining); striae feebly impressed, punctures very slightly larger than on disc; interstriae twice as wide as striae, each uniseriately, rather sparsely granulate (about 6-8 granules on each), granules rather small, usually pointed, often irregular in size, smaller to obsolete on apical fourth; posterolateral margin abruptly rounded, a few small, scattered granules on its crest. Vestiture of fine, moderately long, interstrial hair, often abraded on disc and sides; each seta on declivity up to twice as long as distance between rows.

Male.- Length 1.7 mm ; similar to female except eye reduced in size, anterior margin of pronotum more broadly rounded; asperities smaller, summit flat or feebly impressed; all details of sculpture poorly formed.

## Distribution. - Veracruz to Brazil.

MESICO: Chiapas: Palenque Ruins. Veracruz: Coatzocoalcos, Lago Catemaco. GUATEMALA: Volcán Pacava in Esquintla. COSTA RICA: Finca Gromaco on Río Coto Brus, Rincón de Osa, and Volcán in Puntarenas, Río Damitas (Dota Mts.) and San José in San José, Tapantí and Volcan Irazu in Cartago, Guápiles and Finca La Lola in Limón. PANAMA: Barro Colorado Island and Gatun Dam in the Canal Zone, Volcán Chiriquí in Chiriquí.

Hosts.- Erythrina costaricensis, Ficus sp., Spondias purpurea, Theobroma cacao, and numerous other trees, shrubs, and lianas.

Biology.- This is an abundant, moderately aggressive species that has caused considerable economic loss to horticultural crops and to the lumber industry in Central and South America. It occurs in rather moist areas and it may breed in almost any material larger than about 8 cm in diameter. It is evidently more successful on slightly drier sites or areas of a $\log$ than is normal for ferrugineus (Fabricius) or affinis Eichhoff.

Notes.- The above treatment was based on 116 specimens, two of which were compared to Eggers's material that he had compared to a cotype of posticus. Schedl's syntypes of nocateutonicus were examined, but comparative notes were not recorded. Two specimens in the U.S. National Museum were sent by Eichhoff to Riley; they were labeled "posticus, Mexico, Reitter." These specimens undoubtedly were examined by Eichhoff, but were not part of his original series and cannot be considered syntypes. They are entirely typical of the species and have the dull declivity.

Many specimens assigned to this species from southern South America have the elytral declivity brightly shining. No attempt was made to determine if that form represents a normal variation within a population or a sibling species.

## 44. Xylcborus concentus Wood

Xylehorus coneentus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):39 (Holotype, female; Tapantí, Cartago, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from parallelocollis Eggers by the more narrowly convex declivity on the transverse axis, by the serrate posterolateral margin of the declivity, and by the shorter interstrial bristles on the declivity.

Female.- Length $2.5-2.7 \mathrm{~mm}, 2.7$ times as long as wide; color dark brown.

Frons and pronotum as in caraibicus Eggers except pronotum 1.15 times as long as wide.

Elytra 1.7 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on slightly less than basal two-thirds, tapered, then narrowly rounded behind;
striae not impressed, punctures rather small, distinctly impressed; interstriae twice as wide as striae, punctures very fine, uniseriate. Declivity gradual, transversely convex, suture very feebly convex on lower half; surface rather dull in most specimens; striae not impressed, punctures larger than on disc; interstriae flat, slightly wider than striae, granules small, of uniform size, spaced by distances less than width of an interstriae; posterolateral margin abrupt, subacute, finely serrate. Vestiture largely confined to declivity, consisting of short, stout, interstrial bristles, each bristle equal in length to about one-third width of an interstriae; a few similar, much longer bristles on disc.

Distribution-Costa Rica and Venezuela.
costa rica: Rincón de Osa, Puntarenas, 11-Vili66, 30 m . No. 9, liana; Volcán. Puntarenas, 11-Xil-63, 1000 m , No. 305, tree limb; Tapanti, Cartago, 26-X1-63, $1300 \mathrm{~m}, ~ N o . ~ 265$, Phoebe mexicana; Guápiles, Limón, 22-V111-66, 100 m, No. 101, tree limb. VENEZUELA: 30 km E Palmar, Bolivar, 12-VI-70, 200 m . No. 556, Alexa imperatricis. All were taken by me.

Hosts.- Alexa imperatricia, Phoebe mexicana, etc.

Biology.-Limbs and the boles of trees and lianas from 8 to 20 cm in diameter were attacked.

Notes. - The above treatment was based on the type series of 12 specimens.

## 45. Xyleborus quadratus Blandford

Xylcborus quadratus Blandford, 1898, Biol. Centr. Amer., Coleopt. 4(6):209 (Lectotype, female; Bugaba, Chiriqui, Panama: British Mus. Nat. Hist., present designation)
Diagnosis.- This species is distinguished from concentus Wood by the larger size, by the longer declivital bristles, and," possibly, by the slightly less narrowly rounded posterior margin of the elytra.

Female.- Length $3.6 \mathrm{~mm}, 2.8$ times as long as wide; color very dark brown.

As in concentus except declivital bristles slightly more slender, each almost as long as distance between rows.

Distribution.- Panama.
PANAMA: Bugaba, Chiriquí, G. C. Champion.
Notes. - The first of two female syntypes in the Blandford series of quadratus is here designated as the lectotype of this species. The above treatment was based on the lectotype.
46. Xyleborus parallelocollis Eggers Fig. 186

Xyleborus parallelocollis Eggers, 1933, Mém. Trav. Lab. d'Ent. Mus. Nat. d'Hist. Nat., Paris 1(1):33 (Holotype, female; Nouveau Chantier, French Guiana; Paris Mus.)
Diagnosis.- This species is distinguished from concentus Wood by the transversely impressed, more broadly convex elytral declivity, and by the more acutely elevated, almost smooth, posterolateral margin of the declivity.

Female.- Length 2.3-2.7 mm, 2.6 times as long as wide; color dark brown.

Frons and pronotum as in caraibicus except pronotum 1.11 times as long as wide, its posterior areas subreticulately etched.

Elytra 1.5 times as long as wide, 1.4 times as long as pronotum; outline slightly stouter than in concentus. Declivity moderately steep, broadly convex, suture straight on lower half; surface smooth and shining; strial punctures and interstrial granules as in concentus; posterolateral margin acutely, strongly elevated, its crest almost smooth, devoid of denticles, a feebly concave impression between crest and remainder of declivity. Vestiture largely confined to declivity, consisting of interstrial bristles, each bristle equal in length to from half to two-thirds distance between rows, bristles interspersed with minute hair; sparse setae on disc fine, about twice as long as on declivity.

Distribution.- Costa Rica and French Guiana.

COSTA RICA: Rincón de Osa, Puntarenas, 11 -Vili$66,30 \mathrm{~m}, ~$ No. $52 . \log$, S. L. Wood: Río Damitas, San José, 18-11-64, 250 m, No. 438, log. S. L. Wood; Tapantí, Cartago, 17-IX-63, 1300 m, No. 178, liana, S. L. Wood; Turrialba, Cartago, 9-111-64, 700 m , No. 497, liana, S. L. Wood; Finca La Lola, 27-VI-63, Theobroma cacao. J. L. Saunders. OTHER COUNTRIES: French Guiana.

Hosts.- Theobroma cacao, and other trees and lianas.

Biology.- Specimens were taken from lianas 10 cm in diameter and from logs up to 1 m in diameter.

Notes.- The above treatment was based on the holotype and on 20 other specimens.

## 47. Xyleborus discretus Eggers

Xyleborus discretus Eggers, 1933, Mém. Trav. Lab. d'Ent. Mus. Nat. d'Hist. Nat., Paris $1(1): 29$ (Holotype, female; Marcapata, Peru; U.S. Nat. Mus, 60670)

Xyleborus usticus Wood, 1968, Great Basin Nat. 28:3 (Holoype, female; Bartica District, British Guiana; British Mus. Nat. Hist.); Wood, 1972, Great Basin Nat. 32:198. Synonymy
Diagnosis.- This species is distinguished from semipunctatus Eggers by the distinctly larger size, by the steeper elytral declivity, and by the variable size of the interstrial granules on the declivity.

Female.- Length 2.9-3.3 mm, 2.5 times as long as wide; color dark brown to almost black.

Frons and pronotum as in caraibicus except frons and posterior areas of pronotum more distinctly reticulate; pronotum 1.05 times as long as wide.

Elytra 1.6 times as long as wide, 1.6 times as long as pronotum; disc and outline as in semipunctatus. Declivity confined to posterior 40 percent, rather steep, broadly convex; transversely impressed on lower third, sutural area distinctly concave on lower half of declivity; striae and interstriae as in semipunctatus except interstrial granules with one or two very minute granules alternating with moderately coarse granules; posterolateral margin subacutely elevated, distinctly impressed between its crest and remainder of declivity. Vestiture as in parallelocollis except shorter; length of declivital bristles distinctly shorter than half distance between rows, often abraded.

Male.-Length 2.7 mm ; head and elytra essentially as in female, but with all characters poorly formed; pronotum as in male asper Eggers except anterior area somewhat more strongly concave.

Distribution.- Veracruz to French Guiana and Peru.

MEXICO: Chiapas: Palenque Ruins. COSTA RICA: Rincon de Osa, Puntarenas, 11-Vlll-66, 30 m , No. 52 , $\log$, S. L. Wood. OTHER COUNTRIES: Venezuela, British Guiana, French Guiana, Peru.

Hosts.- Alexa imperatricia (Venezuela), etc.

Biology. - Specimens were taken from logs 30 to 100 cm in diameter.

Notes.- The above treatment was based on the holotype of discretus, on a topotypic paratype of usticus, and on 71 other specimens, 2 of which were compared to the holotype of discretus.

## 48. Xyleborus schildi Schedl

Xyleborus schildi Schedl, 1935, Archiv. Instit. Biol. Veg. 2:94 (Holotype, female; Turrialba, Costa Rica; Schedl Coll.)
Diagnosis.- This species superficially resembles a small spathipennis Eichhoff except that the anterior margin of the pronotum is unarmed. It is distinguished from the distantly related tribulatus Wood as indicated in the above key.

Female.- Length 3.4-4.0 mm, 2.4 times as long as wide; color dark brown.

Frons and pronotum as in tribulatus.
Elytra 1.5 times as long as wide; outline as in tribulatus except stouter; disc occupying slightly less than basal half, shining, except striae and interstriae 1 dull; striae feebly impressed, punctures very fine, shallow, interstriae smooth, four to five times as wide as striae, interstriae becoming distinctly wider toward declivity, punctures confused, almost as large as those of striae. Declivity gradual, broadly convex, dull; very similar to tribulatus except more broadly convex, surface smooth but shagreened; striae not impressed, punctures as on disc; interstrial punctures uniseriate except confused on 1 , two or three punctures on each interstriae finely granulate; posterolateral margin less acute than in tribulatus. Vestiture restricted to one short, stout bristle at each declivital granule.

Distribution.- Costa Rica to Colombia.
COSTA RICA: Turrialba, $800 \mathrm{~m}, \mathrm{~S} . \mathrm{L} . \mathrm{G}$. Schild. COLOMBIA: 8 km S Colonia, Valle de Cauca, 9 -vil- 70,30 m, No. 6.47, Rheedia madruño, S. L. Wood.

Notes. - The above treatment was based on the holotype and on one other specimen.

## 49. Xyleborus tribulatus Wood

Xylehorus tribulatus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):39 (Holotype, female: Río Damitas, Dota Mts., San José, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished $^{\text {in }}$ from semipunctatus Eggers except as noted in the following description.

Female.-Length $3.8 \mathrm{~mm}, 2.4$ times as long as wide; color very dark brown.

Frons and pronotum as in semipunctatus except punctures on posterior half of pronotum distinctly larger, closer.

Elytra as in semipunctatus except discal striae 2 distinctly sinuate; interstriae 2 and 3
on disc distinctly confused; strial punctures on dise and declivity distinctly larger, interstriae on disc three times as wide as striae (four times as wide in semipunctatus). Declivity as in sempunctatus except as noted.

Distribution.- Costa Rica.
COSTA RICA: Rio Damitas, Dota Mts., San José, 22-Vill-63, 250 m , No. 126, liana, S. L. Wood.

Notes.- The above treatment was based on the female holotype.

## 50. Xyleborus semipunctatus Eggers

Xyleborus semipunctatus Eggers, 1933, Mém. Trav. Lab. d'Ent. Mus. Nat. d'Hist. Nat., Paris 1(1):30 (Holotype, female; St. Laurent du Maroni, French Guiana; Paris Mus.
Diagnosis.- This species is distinguished from discretus Eggers by the smaller size and by the more gradual declivity with the interstrial granules of uniformly small size.

Female.- Length 2.3-2.6 mm, 2.4 times as long as wide; color dark brown.

Frons and pronotum as in caraibicus Eggers, pronotum 1.1 times as long as wide.

Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; disc as in parallelocollis Eggers; outline as parallelocollis except more broadly rounded at basal and lateral margins of declivity; suture weakly, distinctly concave on lower half of declivity; declivital striae weakly impressed, punctures and interstrial granules as in parallelocollis; posterolateral margin as in parallelocollis except more distinctly impressed between its crest and remainder of declivity. Vestiture as in concentus Wood but slightly shorter, finer.
Distribution.- Costa Rica and Colombia to French Guiana.

COSTA RICA: Rincón de Osa, Puntarenas, Il-VIII$66,30 \mathrm{~m}$. No. 90, liana, S. L. Wood. COLOMBIA: San Marcos, Valles, VII-59, $550 \mathrm{~m}, \mathrm{C}$. Ramos. VENEZUELA: 30 km E Palmar, Bolivar, 12-di-70, No. 543 in Jaearanda copaia, No. 556 in Alexa imperatricia, S. L. Wood.

Hosts.- Alexa imperatricia, Jacaranda copaia, etc.

Biology.- Specimens were taken from material 5 to 30 cm in diameter.

Notes. - The above treatment was based on the holotype and on 11 other specimens, several of which were compared directly to the type. Apparently a cotype in the Eggers collection and other specimens in the Schedl collection are of parallelocollis and do not agree with the holotype.

## 51. Xyleborus tumucensis Hagedorn

Xyleborus tumucensis Hagedorn, 1905, Bull. Mus. d'Hist. Nat., Paris 6:4I4 (Lectotype, female; Rivière Lunier, Tumuc-Humac, French Guiana; Paris Mus., present designation)
Xyleborus guayanensis Eggers, 1933, Mém. Trav. Lab. d'Ent. Mus. Nat. d'Hist. Nat., Paris 1(1):28 (Syntypes, male and female; Nouveau Chantier, French Cuiana; Paris Mus.); Wood. 1972. Great Basin Nat. 32:200. Synonymy
Diagnosis.- This species is distinguished form geayi Hagedorn by the larger size, by the confused strial punctures on both disc and declivity, and by the slightly stouter body form.

Female.- Length $3.5-3.8 \mathrm{~mm}$ (lectotype 3.7 mm ), 2.4 times as long as wide; color dark reddish brown.

## Frons as in caraibicus Eggers.

Pronotum 1.11 times as long as wide; widest one-third length from base, sides weakly arcuate and converging anteriorly, rather narrowly rounded in front; summit distinctly behind middle; anterior slope rather coarsely asperate; posterior half with lateral areas reticulate, becoming subreticulate to shining behind summit, punctures fine, shallow, moderately close. Vestiture confined to margins, sparse.

Elytra 1.4 times as long as wide, 1.3 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; dise occupying basal twothirds of elytral length; striae not impressed, punctures rather small, rather strongly confused except near base; interstriae at base three times as wide as striae, punctures uniseriate, finely granulate, almost as large as those of striae. Declivity rather steep, rather broadly flattened; strial punctures moderately large, shallow, confused; interstriae marked only by pointed tubercles, about three or four tubercles on each interstriae except 2 usually armed only near base and apex; posterolateral margin subacute, armed by a few fine granules. Vestiture of interstrial bristles, those on declivity slightly shorter than distance between rows, longer on disc.

Distribution.- Costa Rica and French Guiana.

COSTA RICA: Rincón de Osa, Puntarenas, 11-VIII$66,30 \mathrm{~m}$, No. 63, Bursera simarubra, No. 52, log, S. L. Wood.

Host. - Bursera simarubra, etc.
Biology.- Specimens were taken from logs 30 to 100 cm in diameter.

Notes. - The first of three female syntypes of tumucensis has been labeled type. It is in the Paris Museum and is here designated as the lectotype of tumucensis Hagedorn. The lectotype of tumucensis, the male syntype and two female cotypes of guayanensis, and nine other specimens were used as the basis for the above treatment. The female syntype of guayanensis is not in the Paris Museum, where it was originally deposited. Eggers (1933) incorrectly applied the name tumucensis to specimens of geayi Hagedorn and, as a result, named the synonym guayanensis.

## 52. Xyleborus geayi Hagedorn

Xylehorus geayi Hagedorn. 1905, Bull. Mus. dHist. Nat., Paris 6:413 (Lectotype, female; Camopi, French Guiana; Paris Mus., present designation)
Diagnosis.- This species is distinguished from tumucensis Hagedorn by the smaller size, by the more slender body form, and by the uniseriate strial punctures on both disc and declivity.

Female.- Length 2.8-3.1 mm (lectotype 2.8 mm ), 2.55 times as long as wide; color dark brown to almost black.

Frons and pronotum as in tumucensis except pronotum 1.15 times as long as wide; posterior area rather dull, obscurely or not at all reticulate, punctures smaller.

Elytra 1.5 times as long as wide, 1.35 times as long as pronotum; outline about as in tumucensis except more slender; striae not impressed, punctures rather small, shallow, very close, slightly confused on posterior half of disc; interstriae almost smooth, three to four times as wide as striae, punctures uniseriate, almost as large as those of striae, granulate on anterior margins. Declivity about as in tumucensis, strial punctures much larger than on disc, in rows, tubercles similarly placed but slightly smaller. Vestiture as in tumucensis except slightly longer, obsolete on declivital face except where tubercles arise.

Distribution.- Costa Rica and Colombia to French Guiana.

Costa RICA: Rincón de Ota, Puntarenas, H-Vinl66, 30 m . No. $52 . \log , \mathrm{S} . \mathrm{L}$. Wood: Río Damitas. Dota Mts., San José, 22-V111-64, 250 m , tree stump. S. L. Wood. OTHER COUNTRIES: Colombia, Veneznela, British Guiana, and French Cuiana.

Host.- Sloania multiflora (Colombia), etc.
Biology. - Specimens were cut from logs 20 to 80 cm in diameter.

Notes. - The above treatment was based on the first female syntype, labeled type, in the Hagedorn series at the Paris Museum. and on 43 other specimens. The first syntype of geayi Hagedom in the Paris Museum has been regarded as the type, although it has not been so designated: I here designate it the lectotype of this species.

## 53. Xyleborus grandis Eichhoff

Xyleborus grandis Eichhoff, 1s69, Berliner Ent. Zeitschr. 12:281 Holotype, female; Colombia: Brussels Nus.)
Diagnosis. - The true affinities of this species are uncertain. It is distinguished from tumucensis Hagedorn and geayi Hagedom by the more gradual declivity, by the minute subgranular irregularities on the pronotal disc, and by the confused punctures on declivital interstriae 1,2 , and 3 .

Female.- Length $4.2-4.4 \mathrm{~mm}, 2.5$ times as long as wide; color dark brown.

Frons as in caraibicus Eggers.
Pronotum 1.10 times as long as wide; widest slightly behind middle, sides weakly arcuate on basal two-thirds, broadly rounded in front; anterior margin subserrate; summit slightly behind middle; finely, closely asperate on anterior half, asperities gradually decreasing in size posteriorly to base, area behind summit shining, very closely, shallowly punctured, posterior margins of punctures subgranulate. Vestiture confined to marginal areas, sparse.

Elytra 1.5 times as long as wide, 1.5 times as long as pronotum; sides straight on basal half, slightly wider at base of declivity, rather broadly rounded, then rather narrowly rounded behind; disc confined to basal half; striae weakly impressed, punctures very close, rather large, shallow; interstriae about twice as wide as striae, smooth, shining, punctures fine, confused, moderately abundant, somewhat uniseriate toward base on
odd-numbered interstriae. Declivity commencing at middle, gradual, very broadly convex; striae not impressed, punctures uniseriate on dise, usually slightly confused near middle of declivity; interstrial punctures confused, larger than on disc except on 1 , their anterior margins usually feebly granulate; about four widely spaced, pointed tubercles on each interstriae on basal twothirds, except only two on 2; posterolateral margin narrowly rounded, its crest finely granulate. Vestiture of rather widely spaced. slender, interstrial bristles, each one and onehalf to two times length of a bristle.

Only available male with anterior third of pronotum severed, evidently resembling male spathipennis.

Distribution.- Costa Rica to Colombia.
COSTI RICA: Tapantí, Cartago, 17-IX-63, 1300 m , No. Bhi beres S. Hood.

Biologx:-Specimens were removed from a decaving $\log 80 \mathrm{~cm}$ in diameter.

Notes. - The above treatment was based on the holotype and on seven other specimens.

## 54. Xyleborus cismiae Wood Fig. Isfi

Xyldhorus tismiae Wood. 197t, Brighan Young Univ. Sci. Bull. Biol. Ser. 19(1):39 (Holotype, female; Roo Damita, Dota Mts., San Jose, Costa Rica; Wrood Coll.)
Diagnosis.- This species is distinguished from costaricensis Blandford by the shorter, steeper declivity, which is strongly, transversely impressed on the lower half, by the smooth, shining declivital surface, and by the larger declivital granules. The costaricensis group of species is characterized by the slightly protuberant, smooth, peculiarly reti culate frons that is devoid of punctures, by the tapered posterior half of the elytra, and by the long, rather narrow declivity.

Female. - Length $3.3-3.7 \mathrm{~mm}, 2.6$ times as long as wide; color dark brown.

Frons shallowly, transversely impressed between eyes, weakly inflated below; surface smooth, with very fine reticulation below, more coarsely reticulate toward vertex, punctures rather small, sparse, mostly confined to lateral areas, none on lower third; vestiture very sparse, hairlike, inconspicuous.

Pronotum 1.13 times as long as wide; sides almost straight and parallel on basal half,
rather narrowly rounded in front; summit at middle; anterior half rather finely asperate; posterior areas very finely subreticulate, punctures minute, distinct, rather sparse.

Elytra 1.8 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal half, then rather strongly tapered, rather narrowly rounded behind; striae not impressed, punctures small, distinct, spaced within a row by one to two diameters of a puncture; interstriae smooth, moderately shining, punctures very minute, distinct, uniseriate. Declivity occupying slightly more than posterior third, strongly, transversely impressed on lower half; transversely flat; longitudinally concave; striae curved toward suture near apex, punctures almost twice as large as on disc; interstriae shining, armed by rows of small granules, alternate granules slightly larger; posterolateral margin narrowly rounded, its crest with a few feeble granules.

Distribution.-Costa Rica and Venezuela.

COSTA RICA: Río Damitas, Dota Mts.. San José, $22-$ VIII-63, 250 m . No. I26, Vismia guayanensis, S. L. Wood. VENEZUELA: Rancho Grande in Pittier Nat. Pk., Aragua, 9-IV-70, 1100 m , No. 43.3. Guttiferae (very near but apparently not Vismia), S. L. Wood.

Hosts.- Vismia guayanensis, and Guttiferae sp.

Biology.- Specimens were taken from small, cut trees 6-10 cm in diameter.

Notes.- The above treatment was based on the type series of 12 specimens.

## 55a. Xyleborus demissus Wood

Xyleborus demissus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):40 (Holotype, female; Rincón de Osa, Puntarenas, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from deplanatus Eggers by the more slender body form, by the shorter declivity, by the two sizes of interstrial tubercles on the declivity, and by the less strongly serrate posterolateral margin of the declivity.

Female.- Length $2.0 \mathrm{~mm}, 2.9$ times as long as wide; color dark brown.

Frons and pronotum as in deplanatus except pronotum 1.21 times as long as wide.

Elytra 1.7 times as long as wide, 1.5 times as long as pronotum; sides straight and parallel on basal half, then slightly tapered,
narrowly rounded behind, weakly emarginate at suture; disc occupying slightly more than basal half; striae not impressed, punctures small, shallow, distinct; interstriae smooth, shining, three times as wide as striae, punctures uniseriate, slightly smaller than those of striae, their anterior margins feebly granulate at base, becoming more distinctly granulate posteriorly. Declivity rather gradual, moderately convex on both axes; striae not impressed, punctures slightly larger than on dise, lateral margins of punctures on 2 and 3 weakly granulate; interstriae shining, about twice as wide as striae, each armed by a row of granules, granules mostly small except on 2 and 3 distinctly larger granules alternate with small ones. Vestiture of rows of fine, short, strial hair, and interstrial rows of short, almost scalelike bristles, each bristle onethird to one-half as long as distance between rows, slightly closer within a row, each three to five times as long as wide.

Distribution.- Costa Rica.
costa rica: Rincón de Osa, Puntarenas, il-ViII$66,30 \mathrm{~m}, \mathrm{No} .70, \log 20 \mathrm{~cm}$ in diameter, S. L. Wood.

Notes.- The above treatment was based on the holotype.

## 55b.-Xyleborus praestans Wood

Xyleborus praestans Wood, 1980, Great Basin Nat. 40:358 (Holotype, female; Cerro Punta, Chiriquí, Panama; Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from meritus Wood by the larger size, by the different elytral declivity, and by other characters cited below.

Female.- Length $3.9 \mathrm{~mm}, 2.9$ times as long as wide; color dark brown.

Frons and pronotum as in meritus except pronotal summit more subacutely elevated.

Elytra about as in meritus except declivity slightly steeper, more nearly convex, more broadly rounded behind; interstrial punctures on disc more nearly obsolete, irregular interstrial lines on disc more conspicuous; strial punctures on declivity more distinct, not larger than those on disc, interstrial tubercles on 1 and 2 not as close, very slightly larger.

Distribution.- Panama.
PANAMA: Cerro Punta, Chiqiruí, 3I-V-72, 2000-2500 m, T. L. and L. J. Erwin.

Notes.- The above treatment was based on the holotype.

## 56. Xyleborus meritus Wood

Fig. 186
Xyleborus meritus Wood, 1972, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(I):40 (Holotype, female; Tapantí, Cartago, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from vismiae Wood by the slightly larger size, by the more gradual, more nearly flattened elytral declivity, and by the much finer interstrial granules on the declivity.

Female.- Length $2.8-3.4 \mathrm{~mm}, 2.8$ times as long as wide; color very dark brown.

Frons, pronotum ( 1.13 times as long as wide), and elytral disc as in vismiae.

Elytra 1.8 times as long as wide, 1.6 times as long as pronotum; outline as in vismiae. Declivity occupying slightly less than posterior half of elytral length, its lower half very shallowly concave; striae not impressed, curving toward suture near apex, punctures almost twice as large as on disc; interstriae smooth, shining, with widely spaced fine granules, those on lower half of 2 and 3
smaller, sometimes almost obsolete. Vestiture sparse, of fine hair, length on declivity equal to about half width of an interstriae.

Distribution.- Costa Rica.
COSTA RICA: Tapantí, Cartago, $1300 \mathrm{~m}, 2$-VII-63, No. 7, liana, 3-VII-63, No. 17, Conostegia oerstediana, 17-IX-6.3, No. 182, tree branch, No. 184, Miconia caudata, 26-XI-63, No. 265, Phoebe mexicana, S. L. Wood; I4 km SE Cartago, Cartago, 24-IX-63, 1800 m , No. 204, Miconia globuliflora, No. 200, Myrica pubescens, S. L. Wood.

Hosrs.-Conostegia oerstediana, Miconia caudata, M. globuliflora, Myrica pubescens, and Phoebe mexicana.

Biology. - This species was taken from material 6-15 cm in diameter.

Notes.- The above treatment was based on the type series of 25 specimens.

## 57. Xyleborus costaricensis Blandford Fig. 186

Nyleborus costaricensis Blandford, 1898, Biol. Centr. Amer., Coleopt. 4(6):210 (Holotype, female: Volcán Irazu, Costa Rica; British Mus. Nat. Hist.)

$$
f
$$

Fig. I86. Xyleborus spp., female declivities with setae omitted: a, prolatus; b, costaricensis; c, vismiae; d, parallelocollis; e, meritus; f, pseudotenuis.

Xyleborus nevermanni SchedI, 1935, Archiv. Inst. Biol. Veget., Río de Janiero 2:93 (Syntypes, females; Vara Blanca, Heredia, Costa Rica: Schedl and Nevermann Coll.); Wood, 1979. Great Basin Nat. 39: I36. Synomymy
Diagnosis.- This species is distinguished from meritus Wood by the larger size and by the longer, dull, more flattened elytral declivity.

Female.- Length $4.0-4.4 \mathrm{~mm}, 2.8$ times as long as wide; color dark brown.

Frons and pronotum as in meritus.
Elytra 1.7 times as long as wide, 1.7 times as long as pronotum; outline about as in meritus except more broadly rounded behind; dise occupying very slightly less than basal half; striae not impressed, punctures rather small, shallow; interstriae three times as wide as striae, smooth, shining punctures minute, virtually obsolete. Declivity rather gradual, narrowly flattened toward base, more broadly, subconcavely flattened on lower third to striae 3; surface dull; strial punctures almost twice as wide as on disc; interstriae twice as wide as striae, smooth, with small uniseriate, sparse granules on each interstriae from base to apex; spacing for granules about equal to width of an interstriae. Vestiture confined to declivity, of sparse rows of interstrial hairlike setae, each seta about equal in length to distance between rows, one to two times length of a seta within a row.

Distribution.- Costa Rica and Panama.
COSTA RICA: Volcán Irazu, G. C. Champion; 14 km SE Cartago, Cartago, 24-IX-63, 1800 m, No. 194. log, S. L. Wood: Tapantí, Cartago, 17-X-63, 1300 m , No. 178 , liana, 24-X-63, No. 265, Phoebe mexicana, S. L. Wood. PANAMA: Cerro Punta, Chiriquí, 11-I-64, 1800 m , No. 386, tree stump, S. L. Wood; Potrerillos, Chiriquí, IsIV, 20-V-33.

Hosts. - Phoeloe mexicana, etc.
Biology.- Specimens were taken from recently cut material 8-30 cm in diameter.

Notes. - The above treatment was based on 38 specimens, 2 of which were compared directly to the holotype of costaricensis. The Schedl syntype and the syntype in the U.S. National Museum of nevermanni were examined and are of this species.

## 58. Xyleborus prolatus Wood Fig. 186

Xyleborus prolatus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(I):41 (Holotype, female; Tapantí, Cartago, Costa Rica; Wood Coll.)

Diagnosis.- This species is distinguished from costaricensis Blandford by the larger size, by the longer, more strongly impressed declivity, and by the near absence of granules on declivital interstriae 1 and 2 .

Female.- Length 4.0-4.4 mm, 2.8 times as long as wide; color dark brown.

Frons and pronotum as in costaricensis.
Elytra 1.7 times as long as wide, 1.7 times as long as pronotum; outline about as in costaricensis except more strongly tapered on posterior half, more narrowly rounded behind; dise confined to basal third, as in costaricensis. Declivity very gradual, shallowly, broadly bisulcate; surface dull; strial punctures twice as large as on disc; interstriae almost twice as wide as striae, smooth, 1 distinctly elevated toward suture, 2 broadly, subconcavely impressed, 3 distinctly, gradually elevated toward broad summit at striae 4,3 and 4 each with a row of widely spaced, moderately large granules, 1 and 2 sometimes with one or two smaller granules near apex (one paratype with five granules on 2 on left side). Vestiture as in costaricensis except almost entirely absent on declivital interstriae 1 and 2.

Distribution.- Costa Rica.
COSTA RICA: Tapantí, Cartago, 24-X-63, 1300 m , No. 265, Phoebe mexicana, S. L. Wood.

Biology.- This species was taken from a cut limb $6-10 \mathrm{~cm}$ in diameter.

Notes. - The above treatment was based on the type series of nine specimens.

## 59. Xyleborus sparsipilosus Eggers

Xyleborus sparsipilosus Eggers, 1933, Mém. Trav. Lab. d'Ent. Mus. Nat. d'Hist. Nat. Paris I(1):34 (Holotype, female; Nouveau Chantier, French Guiana; Paris Mus.)
Xyleborus inconceniens Schedl, 1948, Rev. de Ent., Río de Janeiro 19:577 (Holotype, female; Hamburgfarm on Río Reventazón, Limón, Costa Rica; Schedl Coll.); Wood, 1972. Great Basin Nat. 32:199. Synonymy
Diagnosis.- This species is distinguished from productus Hagedorn by the smaller size, by the more broadly rounded elytral apex, which is not produced on the apical fourth of the declivity, and by the smaller major denticle on declivital interstriae 3.

Female.- Length 2.2-2.4 mm, 2.9 times as long as wide; color very dark reddish brown.

Frons broadly convex, epistomal margin weakly elevated; surface reticulate, punctures rather sparse, shallow, not sharply impressed, irregular in size.

Pronotum 1.2 times as long as wide; widest on basal half, sides weakly arcuate and almost subparallel on slightly more than basal half, rather narrowly rounded in front; summit at middle; anterior slope rather coarsely asperate; posterior areas almost smooth and shining, with irregular, sometimes obscure areas of reticulation, punctures fine, sparse. Vestiture sparse, confined to marginal areas.

Elytra 1.7 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; disc occupying basal twothirds; striae not impressed, punctures rather small, close; interstriae twice as wide as striae, smooth, shining, punctures uniseriate. one or two minute punctures alternating with one larger, subgranulate puncture. Declivity moderately steep, broadly convex on transverse axis; suture straight on lower half; strial punctures distinctly larger than on dise; interstriae slightly wider than striae; interstriae 1 armed by about five pointed granules, one on upper third and one on lower third slightly larger, 2 entirely unarmed, with a row of closely placed punctures, 3 armed by two to seven granules, two on middle third larger, about equal in size to those on 1 ; lateral areas with a few fine granules; posterolateral margin subacute, crest sinuate, unarmed. Vestiture consisting of very minute strial hair and rows of interstrial setae; one or two minute interstrial setae alternate with long, coarse, interstrial bristles, bristles each about twice as long as distance between rows, spaced within a row by length of a bristle; bristles absent on declivital interstriae 2.

Distribution.- Costa Rica and Panama to French Guiana.

COSTA RICA: Rincón de Osa, Puntarenas, II-VIII$66,30 \mathrm{~m}$, No. $52, \log , \mathrm{~S} . \mathrm{L}$. Wood; Finca Gromaco in Rio Coto Brus, Puntarenas, I4-VII-63, 500 m , No. 62, Ficus, S. L. Wood, Río Damitas, Dota Mts., San José, 22-VIII$63,250 \mathrm{~m}$, No. I24, tree stump, I8-II-64, No. 430, in flight, S. L. Wood; Moravia, Cartago, II-III-64, 500 m , No. 470, log, S. L. Wood; Turrialba, Cartago, 9-III-64, 700 m, No. 496, tree limb, S. L. Wood; Hamburgfarm on Río Reventazón, Limón, 28-VI-34, fliegend bei Virola warburgii, F. Nevermann. PANAMA: Cerro Campana, 2-VIII-70, 900 m .

Hosts.- Ficus sp., Virola warburgii, etc.
Biology.- Specimens were taken from material $10-60 \mathrm{~cm}$ in diameter.

Notes. - The above treatment was based on the holotype of sparsipilosus, on my homotype that was compared directly to the holotype of inconveniens, and on 20 other specimens.

## 60. Nyleborus productus Hagedorn

Xelchorus productus Hagedorn, 1905. Bull. Mus. d'Hist. Nat., Paris 6:414 (Lectotype. female; Ras. Mahury, French Guiana: Paris Mus., present designation)
Diagnosis.- This species is distinguished from sparsipilosus Eggers by the larger size, by the narrowly produced apical third of the elytral declivity, and by the slightly enlarged denticle on declivital interstriae 3 .

Female.- Length 2.5-2.7 mm (lectotype $3.0 \mathrm{~mm}), 2.7$ times as long as wide; color very dark reddish brown.

Frons and pronotum as in sparsipilosus except frons more coarsely punctured, pronotum more broadly, subangulately rounded in front, posterior areas more uniformly reticulate.

Elytra 1.6 times as long as wide, 1.5 times as long as pronotum; sides straight and parallel on basal two-thirds, subacutely acuminate behind; dise occupying basal two-thirds of elytral length; disc as in sparsipilosus. Declivity moderately steep, broadly convex on upper half, median area of apical fourth produced to sutural apex; striae about as on disc except punctures less distinct; interstriae 1 armed by about five granules, one sometimes distinctly larger, 2 irregular, punctures sometimes feebly granulate, 3 armed by one to about three granules, one near middle of declivity distinctly larger, usually larger than those on 1 ; lateral areas with a few smaller granules; posterolateral margin narrowly rounded, its crest sometimes bearing two or three granules. Vestiture as in sparsipilosus except difference in long and short interstrial setae less pronounced; one or more long setae on declivital interstriae 2.

Distribution.- Costa Rica to French Guiana.
COSTA RICA: Rincón de Osa, Puntarenas, 11-VIII66, I m, No. 79. Rhizophora mangle. S. L. Wood. PANAl1A: Summit Gardens, Canal Zone, 9-V-71, E. G. Riley.

Biology.-Specimens were taken from a dying mangrove tree 20 cm in diameter. The galleries appeared identical to those of ferrugineus (Fabricius).

Notes.- The above treatment was based on 28 specimens that were compared directly to Hagedorn's type; the type is distinctly larger, but agrees in all other respects. Hagedorn labeled his first of three syntypes as the type; I here designate that specimen as the lectotype of productus Hagedorn.

## 61. Xyleborus titubanter Schedl

Xyleborus titubanter Schedl, 1948, Rev. de Ent. 19:578 (Holotype, female; Mexico; SchedI Coll.)
Xyleborus dissidens Wood, 1972, Brigham Young Univ. Sci. Bull., Biol. Ser. (Holotype, female; 9 km NE Teziutlan, Puebla, Mexico: Wood Coll.); Wood, 1975, Great Basin Nat. 35:23. Synonymy
Diagnosis.- This species is placed here because of the slender pronotum and steep elytral declivity; nevertheless, it probably is more closely related to the species placed in the subgenus Euwallacea. In addition to the slender pronotum with its procurved anterior margin, this species has the elytral declivity steep, convex, and interstriae 1-3 equally armed by pointed granules.

Female.- Length $3.0-3.2 \mathrm{~mm}, 3.0$ times as long as wide; color black.

Frons as in costaricensis Blandford but with lower area less strongly inflated.

Pronotum 1.22 times as long as wide; as in sparsipilosus except posterior areas subreticulate.

Elytra 1.8 times as long as wide, 1.5 times as long as pronotum; sides straight and parallel on slightly more than basal two-thirds, rather broadly rounded behind; dise occupying slightly more than basal two-thirds; striae not impressed, punctures rather small, distinct, spaced within a row by diameter of a puncture; interstriae smooth, shining, twice as wide as striae, punctures uniseriate, minute, distinct, almost obsolete. Declivity steep, rather broadly convex; striae about as on disc; interstriae 1-3 each equally armed by six to ten pointed granules of slightly irregular size; posterolateral margin obtuse, abrupt. Vestiture confined to declivity, of rows of rather coarse, interstrial setae, each seta about one and one-half times as long as
distance between rows, more widely spaced within a row.

Distribution.- Puebla.
MEXICO: Puebla: 9 km NE Teziutlan, 2-VII-67, 1500 m , No. 141 in Alnus, No. 151 in a log, No. 147 in flight. by S. L. Wood.

Biology.- Specimens were taken from cordwood 40 cm in diameter.

Notes.- The above treatment was based on the holotype of titubanter and on the type series of six specimens of dissidens.

## 62. Xyleborus imbellis Blandford

Xyleborus imbellis Blandford, 1898, Biol. Centr. Amer., Coleopt. $\mathbf{4}(6): 211$ (Holotype, female; San Juan, Verapaz, Guatemala; British Mus. Nat. Hist.)
Diagnosis.- This unique species is distinguished from other American representatives of the genus by the large size, by the small, deep, confused elytral punctures on both disc and declivity, by the short, fine, abundant elytral hair, and by the different pronotum.

Female.- Length 4.4-4.7 mm, 2.9 times as long as wide; color reddish brown.

Frons moderately convex; surface with close, flat, shining, moderately coarse granules, almost subaciculate, median line smooth, shining; vestiture fine, rather long, epistomal brush conspicuous. Antennal club with one obscure suture on anterior face, none on posterior face.

Pronotum 1.2 times as long as wide, slightly wider than elytra; widest at middle, sides feebly arcuate from base, rather broadly rounded in front; anterior margin unarmed; summit indefinite, anterior to middle; anterior slope rather steep, asperities on its anterior fourth resembling granules, those at and near summit resembling scales; posterior areas smooth, shining, punctures deep, rather close, of irregular, small size. Vestiture of fine, moderately abundant hair.

Elytra 1.7 times as long as wide, 1.3 times as long as pronotum; sides almost straight and parallel on basal half, slightly tapered to base of declivity, then rather broadly rounded behind; disc occupying basal 65 percent of elytral length; striae usually not indicated, punctures may be in rows or confused, only slightly larger than those of interstriae; interstriae smooth, shining, punctures small, deep, rather abundant, confused except almost uniseriate near declivity in some specimens.

Declivity moderately steep, lower two-thirds almost flat on median half; posterolateral margin rounded; surface smooth, shining, punctures confused, as on disc. Vestiture of fine, rather short hair from base to apex, somewhat more abundant on declivity.

Distribution.- Veracruz to El Salvador.
MEXICO: Veracruz: El Palmar, 4-lV-57, Hevea brasiliensis, R. Coronado. GUATEMALA: San Juan in Verapaz, G. C. Champion. EL SALVADOR: San Salvador, 2-IV-30, No. 102, S. Calderon.

Notes.- The above treatment was based on the holotype and on four other specimens.

## 63. Xyleborus ferrugineus (Fabricius) <br> Figs. 187-188

Bostrichus ferrugineus Fabricius, 1801, Systema eleutheratorum 2:388 (Lectotype, female; America meridionali; Copenhagen Mus., present designation)
Xyleborus ferrugineus: Ferrari, 1867, Forst- und Baumzuchtschädlichen Borkenkäfer, p. 23
Tomicus trypanaeoides Wollaston, I867, Coleoptera Hesperidum, p. 114 (Syntypes, fenales; S. lago and Fogo, Cape Verde Islands; British Mus. Nat. Hist.); Schedl, 1960, Coleopt. Bull. 14:9. Synonymy
Xyleborus fuscatus Eichhoff, 1868, Berliner Ent. Zeitschr. 11:400 (Syntypes; Carolina and Colombia; presumably lost with Hamburg Mus.); Schedl, 1960. Coleopt. Bull. 14:8. Synonymy
Xyleborus impressus Eichhoff, 1868, Berliner Ent. Zeitschr. 11:400 (Syntypes?; Massachusetts; one "type" in Brussels Mus.); Schedd, 1960, Coleopt. Bull. 14:8. Synonymy

Xyleborus argentinensis Schedl, 1931, Ann. Mag. Nat. Hist. (10)8:345 (Holotype, San Ignacio, Argentina; Schedl Coll.); Schedl, 1960, Coleopt. Bull. 14:8. Synonymy
Xyleborus schedli Eggers, 1934, Ent. Blätt. 30:83 (Holotype, female; 12 km from Atlantic Ocean, Limón, Costa Rica; U.S. Nat. Mus., 60768); Schedl, 1960, Coleopt. Bull. 14:9. Synonymy
Xyleborus notatus Eggers, 1941, Arb. Morph. Taxon Ent. Berlin. Dahlem 8:107 (Holotype, female; 3Riv., Guadeloupe; U.S. Nat. Mus., 60766); Schedl, 1960, Coleopt. Bull. 14:8. Synonymy
Xyleborus subitus Schedl, 1949, Rev. Brasil. Biol. 9:280 (Holotype, female: Chiapas, Mexico; Schedl Coll.); Schedl, 1960, Coleopt. Bull. 14:9. Synonymy
$\mathrm{D}_{1 \mathrm{agnosis}}$ - This is one of the most widely distributed, common, economically important ambrosia beetles in the world. It is easily recognized by the rather slender form, by the reddish brown color, and by the moderately steep, flattened elytral declivity that is armed on interstriae 3 by one pair of rather prominent denticles.

Female. - Length $2.0-3.3 \mathrm{~mm}, 2.7-3.0$ times as long as wide; color reddish brown.

Frons broadly convex; surface reticulate, subshining, punctures rather sparse, small, not sharply impressed; vestiture of sparse, inconspicuous hair.

Pronotum 1.2 times as long as wide; sides almost straight and parallel on basal twothirds, rather narrowly rounded in front; summit at middle; anterior slope rather coarsely, closely asperate; posterior areas mostly smooth, shining, often with obscure indications of reticulation laterally, particularly near asperate areas, punctures fine, sparse, shallow. Sparse hairlike vestiture confined to marginal areas.

Elytra 1.7 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal two-thirds, then slightly tapered, rather broadly rounded behind; disc occupying basal two-thirds; striae feebly if at all impressed, punctures moderately coarse,
rather deep: interstriae about one and onehalf times as wide as striae, smooth, shining, punctures moderately coarse to minute or obsolete, uniseriate, usually widely, irregularly placed. Declivity rather steep, essentially flat
(a slight convexity in some specimens); strial punctures usually slightly larger than on disc; interstriae 1 and 2 flat, unarmed except for one or two pointed granules at base of 1,3 often feebly elevated, armed by one rather

Fig. 187. Xyleborus and Xylehorinus, female declivities: a, Xyleborus obesus; b, Xyleborus sayi; c, Xyleborus dispar: d, Xyleborinus saxeseni: e, Xyleborus celsus; f, Xylehorus ferrugineus. (After Bright 1976:132.)
coarse denticle at middle of declivity, one to three smaller pointed granules often present on basal half; a few rounded granules usually present in lateral areas; posterolateral margin narrowly rounded, its crest usually armed by a series of granules. Vestiture of moderately long interstrial hair, mostly obsolete on declivity.

Male.- Length 1.8 mm ; head and elytra essentially as in female except vertex with a distinct median sulcus, and major denticle on declivity not larger than other granules, all features poorly formed; elytra I.3 times as long as pronotum; pronotum with asperities almost obsolete, anterior third concavely excavated, lateral margins of concavity rather narrowly rounded, anterior margin obtusely produced with a short acute spine medially.

Distribution.- Michigan and Massachusetts to S Arizona and Argentina; tropical Africa; Hawaii to Micronesia.

USA: Alabama, Arizona, Arkansas, District of Columbia, Florida, Georgia, Illinois, Indiana, Kentucky, Louisiana, Maryland, Massachusetts, Michigan, Mississippi. Missouri, New Jersey, New York, North Carolina, Ohio. Pennsylvania, South Carolina, Tennessee, Texas, Virginia, and West Virginia. MEXICO. Chiapas, Guerrero, Jalisco, Nayarit, Oaxaca, Puebla, Quintana Roo, San Luis Potosí, Sinaloa. Sonora. and Veracruz. CENTRAL AMERICA: British Honduras, Costa Rica, El Salvador, Guatemala, Honduras, Nicaragua, and Panama.

Hosts.- Schedl (1962) records 168 host species. The following new American host records are added to his list: Bombacopsis quintana, Cedrela sp., Citrus sp., Couma macrocarpa, Dendropana arboreum, Eschueilera corrugata, Fagara sp., Fissicalyx fendleri, Inga sp., Lecythia sp., Licania sp., Lonchocarpus margaritensis, Melicoccora bijugata, Ochroma sp., Pithacellobium pinnatum, Pouteria anibaefolia, Protium sp., Sacoglothia procera, Spondias purpurea, Swictenia macrophylla, and Vismia sp.

Brology.- This is probably the most destructive species of Scolytidae in tropical areas of the world from sea level to an elevation of about 1500 m . It attacks virtually all species of woody plants, although it is rare in conifers. Normally, it attacks material larger than 10 cm in diameter, but on rare occasions it has been taken from sugar cane and other small stems. It usually attacks cut, broken, unthrifty trees, or stumps either on or near the ground. On certain occasions it attacks
slightly injured, living trees and either hastens or causes the death of its host. Its greatest economic effect is produced on cut logs either in the forest or in temporary storage or docking areas, where the tunnels may render all sapwood totally useless within a very few weeks. They are able to tolerate unusually high temperatures and excessive moisture.

In addition to their activities of perforating saps sod, they are the principal vector of Ce ratocystis fimbriata, which causes a wilt disease of Cacao (Saunders 1965).

As in other Xyleborus, only the female flies to seek a new host. Flight activity occurs primarily at night. The multibranching tunnels usually penetrate all of the sapwood of the host whether it is 2 or 30 cm in depth; their galleries are less common in the heartwood. In addition to the deep galleries, this species may form shallow tunnels that are visible on the surface of wood from which the bark has been peeled; however, these surface tumnels are not always present.

Saunders and Knoke (1967) successfully cultured this species in vitro on an artificial medium in the absence of the symbiotic fungus.

Notes.- In the Copenhagen Museum there are four original Fabricius specimens of ferrugineus. One of these is the Kiel specimen examined by Eggers, one is of affinis

Fig. 18Sa, Xyleborus ferrugineus, female. (After Schedl 1962:425.

Eichhoff, and two are of torquatus Eichhoff. A presumed syntype conspecific with the Kiel specimen is in the Berlin Museum. Although the Kiel specimen is in very poor condition and probably is not the specimen on which the original description was based (the torquatus specimens fit more precisely), I here designate the Kiel specimen as the lectotype of ferrugineus Fabricius to retain the established concept of this species. I have also examined the syntypes of trypanaeoides, bispinatus, confusus, impressus, amplicollis, and insularis, and the holotypes of soltaui, nyssae, argentinensis, hopkinsi, scheld, notatus, and subitus. The first of four syntypes

Fig. 188b. Xylcborus fcrrugineus, galleries. (After Schedl 1962: 453, 455.)
of confusus in the Brussels Museum is here designated as the lectotype of that species.

This species is somewhat variable in size and in certain details of elytral structure. Much of this variation is evidently due to environmental factors, but some of it apparently results from genetic differences. Two or more parthenogenetically produced "clones" occupying the same log can be very strikingly different.

Detailed studies on the biology and genetics of this species are seriously needed.

## 64. Xyleborus affinis Eichhoff

 Fig. 189-190Xyleborns affinis Eichhoff, 1868, Berliner Ent. Zeitschr. 11:401 (Syntypes; America boreali and Cuba; presumably lost with Hamburg Mus., presumed syntypes in U.S. Nat. Mus.)
Xyleborus affinis var. parvus, var. mascarcnsis, var. fuscobrunnens Eichhoff, 1878, Mém. Soc. Roy. Sci. Liége (2)8:372 (Syntypes?' no data; one presumed syntype of fuscobrunneus in Schedl Coll.); Schedl, 1959, Trans. Roy. Ent. Soc. London 111:504 (Synomymy of partns, fuscobrunneus); Wood, 1960, Insects of Micronesia 18(1):71 (Synonymy of mascarensis)
Xylcborus sacchari Hopkins, 1915, U.S. Dept. Agric. Rept. 99:64 (Holotype, female; St. Vincent, West Indies; U.S. Nat. Mus., 7407): Schedl, 1959, Trans. Roy. Ent. Soc. London 111:504. Synonymy Xylcborus subaffinis Eggers. 1933, Mém. Trav. Lab. d'Ent. Mus. Nat. d'Hist. Nat., Paris 1(1):36 (Holotype, female; Nouveau Chantier, French Guiana; Paris Mus.); Schedl, 1959, Trans. Roy. Ent. Soc. London 111:504. Synonymy
Xylcborus proximus Eggers, 1943, Parc Nat. Albert, Mission C. F. de Witte 1933-1935, fasc. 43(10):66 (Holotype, female; Leopoldville, Congo; Terveuren Mus.); Schedl, 1962, Rev. Ent. Mocambique 5:331. Synonymy
Diagnosis.- This abundant pantropical species is distinguished from ferrugineus (Fabricius) by the more gradual, more convex elytral declivity, which has a dull surface, and by the equal, small granules on declivital interstriae 1 and 3 .

Female.- Length $2.0-2.7 \mathrm{~mm}, 2.6-2.9$ times as long as wide; yellowish to reddish brown.

Frons and pronotum as in ferrugineus except reticulation more evident.

Elytra about 1.7 times as long as wide, 1.5 times as long as pronotum; outline about as in ferrugineus; dise occupying slightly less than basal two-thirds of elytral length; striae
not impressed, punctures rather small; interstriae about twice as wide as striae, smooth, shining, punctures uniseriate, moderately close to rather sparse, fine to moderately coarse. Declivity moderately steep, feebly convex on sutural axis, moderately convex on transverse axis; surface dull; striae as on disc; interstriae 1 and 3 feebly elevated, 2 weakly impressed and about equal in width to 1 and 3,1 and 3 each armed by about two to four rather small, pointed granules with a few minute granules interspersed in a uniseriate row, 2 usually with a small, pointed granule near base and another near apex, with a sparse row of very minute granules between, lateral interstriae each with about 1-3 small, pointed granules; posterolateral margin narrowly rounded, its crest armed by about four granules. Vestiture of very minute strial hair, and interstrial rows of coarse erect hair, distinctly coarser on declivity; each interstrial seta as long as distance between rows, similarly spaced within a row, often shorter or abraded on declivity.

Male.- Head and elytra similar to female except all characters less perfectly formed; pronotum as in male ferrugineus except anterior slope evidently less strongly concave, median process on anterior margin much smaller. (Based on one badly shriveled specimen).

Distribution.- Texas and Massachusetts to Argentina, Hawaii to Malaya, and tropical Africa.

USA: Alabama, Delaware, District of Columbia, Florida, Georgia, Illinois, Indiana, Louisiana, Maryland, Massachusetts, Michigan, Mississippi, Missouri, New Jersey, New York, North Carolina, Ohio, Pennsylvania, South Carolina, Texas, Virginia, and West Virginia. All states of Mexico and all countries of Central America.

Hosts.- Schedl (1962) lists 248 host species. To his list are added: Alexa imperatricia, Bombacopsis quinata, Brosimum sp., Bursera simarubra, Cecropia peltata, Cespedesia macrophyla, Clethra hondurensis, Couma macrocarpa, Dendropanax arboreum, Eschweilera corrugata, E. grata, Erythrina costaricensis, Icica allisima, Lecythia sp., Licania sp., Miconia globuliflora, Pouteria anibaefolia, P. egregia, Scaoglothia procera, Schizolobium sp., Sloanea multiflora, Spondias purpurea, Taxodium sp., Terminalia amazonia, Toulicia pulvinata, and Trichilia propingon.

Brology.- The ecological distribution is almost identical to ferrugineus except that it apparently is somewhat less aggressive and may attack smaller material. It has caused a serious economic problem in sugar cane.

The gallery system is very similar to that of ferrugineus, except that surface tumnels on the peeled surface of the wood are a more common occurrence, with the surface tunnels usually more extensive. Moisture conditions evidently determine whether or not the surface tunnels are formed. Adjacent galleries often have comnecting tunnels. More than one generation may inhabit and extend the gallery system.

Notes. - The above treatment was based on the male and female supposed syntypes of affinis that are in the U.S. National Museum, on the holotypes of sacchari and subaffinis, on Schedl's syntype of fuscobrunneus, on cotypes of proximus, on Eggers's homotypes of parvus and mascarensis, and on 1,467 other

Fig. 188c. Xyleborus ferrugineus, galleries. (After Schedl 1962:453, 455.)
specimens. Most specimens of this species are $2.3-2.5 \mathrm{~mm}$ long. In the Ohio Valley it is not uncommon to find specimens as large as 2.7 mm , and occasional specimens as large as 2.8 mm . These larger specimens occur in series
with those of average size. In some tropical areas specimens $2.1-2.3 \mathrm{~mm}$ are more common. Series from the eastern United States can be confusing, because small, dead, tropical specimens may be imported in tropical

Fig. 189a,b. Xyleborus affinis, galleries, with (arrows note larvae) and without tunnels at cambium. (After Schedl 1962:364-365.)
woods, such as balsa, and may be given the same locality label as the larger native population. Other characters are much less variable.

The Hawaiian series named numanus Schedl (1941:114) is identical with affinis except that the declivity is smooth and brightly shining. It probably is a synonym, but proof of this must await studies of genetics.

## 65. Nyleborus celsus Eichhoff Fig. 157

Xylehorus celsus Eichhoff. 156S. Berliner Ent. Zeitechr. II:4(0) (Svitypes, female: American boreali; presumally lost with Hamburg Mus.)
Xyletorus biographus LeConte, 1s6is, Trans, Amer. Ent. Soc. 2:160 (Holutype, male; Illinois; Mur. Comp. Zool. 985): Eichhoff. 157S, Mém. Soc, Rov, Sci.
 Dept. Agric. Div. Ent. Bull. (n.s.) T:L4. Synonymy
Diagnosis.- This species is distinguished from the rather remotely allied affinis Eichhoff by the larger size, by the steep, flat declivity, and by the very wide declivital interstriae 1 , with its enlarged tubercles strongly displaced laterally and apparently on striae 1 or even interstriae 2.

Female.- Length 3.6-4.5 mm (male $2.3-3.0 \mathrm{~mm}$ ), 3.0 times as long as wide; color reddish brown.

Frons and pronotum as in ferrugineus (Fabricius) except anterior margins more broadly rounded, and punctures on posterior areas very fine, closer.

Elytra 1.9 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal four-fifths, very broadly rounded behind; disc occupying basal threefourths; striae feebly if at all impressed, punctures rather small, shallow; interstriae three times as wide as striae, smooth, shining, punctures fine, uniseriate except occasional specimens slightly confused on 2. Declivity steep, almost flat; basal margin of declivity armed by one or two pointed tubercles on each interstriae to about 7 ; surface dull; strial punctures rather small, very shallow, clearly marked, rows strongly curved toward suture near apex; interstriae 1 very wide, smooth, a few very minute punctures, armed by two rather coarse denticles, one each on upper and lower thirds, denticles on extreme lateral margin of interstriae 1 , often appearing to be
on striae 1; interstriae 2 almost as wide as 1 , smooth, with a few very minute punctures, 3 with two or three pointed tubercles forming part of marginal armature; posterolateral margin obtusely subangulate, crest bearing two or three granules. Vestiture of minute strial hair, and interstrial rows of moderately long, rather fine hair on disc, long setae on declivity only where tubercles occur.

Distribution.-Kansas, lowa, and Vermont to Texas and Florida.

Us A: Arkatusas. Connecticut. District of Columbia. Florida. Georgia, Ilmois, Indiana, Iowa, Kansas, Mississippi, Missouri, New Jersey, New York, North Carolina. Olio, Pennstrania, South Carolina. Texas, Vermont. West Virginia.

Host.- Carya spp.
Biology.- Evidently logs and stumps are attacked. According to Hubbard (1897) the gallery system is deep in the wood, with a palmate branching of tunnels from the end of the radial entrance tumnel.

Notes. - The above treatment was based on 418 female specimens, of which one was compared to the male holotype of biographus. The description (Eichhoff 1878) of celsus is sufficiently clear that there is no question concerning the synonymy of this species with biographus.

## 66. Nyleborns colvulus (Fabricius)

Boxtrichus toleulus Fabricins, 1775, Systema Entomologiae. p. 454 Lectotype, female; America ligno Dom a : Rohr, presumahly Cuba: Copenhagen Mus., present designation)
Xyleborus colculus: Eqgers. 1929, Wiener Ent. Zeit. 46:47

Xyleborus grenadensis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:65 (Holotype, female; Grenada, West Indies; U.S. Nat. Mus., 7408); Wood, 1972, Great Basin Nat. 32:200. Synonymy
Xyleborus vagabundus Schedl, 1949, Rev. Brasil Biol. 9:277 (Holotype, female: Mexico; Schedl Coll.); Wood, 1972, Great Basin Nat. 32:200. Synonymy
Diagnosis. - This species is distinguished from affinis Eichhoff by the reddish brown color, by the steeper, more narrowly convex, shining elytral declivity, with the declivital tubercles slightly larger and the posterolateral margin more acute. See also the diagnosis of morulus Blandford.

Female.- Length 2.1-2.8 mm, 2.7-2.9 times as long as wide; color reddish brown.

Frons and pronotum as in ferrugineus (Fabricius).

Elytra 1.8 times as long as wide, 1.6 times as long as pronotum; declivity confined to basal two-thirds; striae not impressed, with punctures small, shallow, widely spaced (northern) to distinctly, weakly impressed, with punctures rather small, moderately impressed, closely placed (southern); interstriae two to three times as wide as striae, smooth, shining, punctures uniseriate, small punctures more or less alternating with moderately large ones. Declivity moderately steep, rather broadly convex; surface almost smooth, shining; striae and punctures about as on dise, distinctly curving toward suture near apex; interstriae 2 feebly impressed, unarmed, punctures almost obsolete, 1 and 3 each armed by two to four widely spaced, pointed tubercles, each tubercle about as high as wide, lateral interstriae with similar, closer, but less regularly placed tubercles; posterolateral margin obtusely angulate, crest irregularly, finely subserrate.

Male.- Length 1.9 mm ; head and elytra approximately as in female, but with all characters poorly formed; pronotum as in male
ferrugineus except anterior impression not as deep, asperities more distinct, anteromedian prominence less strongly developed.

Distribution.- Florida and Baja California to Argentina; Hawaii to Australia and Malaya; tropical Africa and Madagascar.

USA: Florida. MEXICO: Baja California, Chiapas, Guerrero, Jalisco, Mexico, Morelos, Nayarit, Oaxaca, Puebla, Quintana Roo, San Luis Potosí, Tabasco, Yucatán. CENTRAL AMERICA: British Honduras, Costa Rica, Guatemala, Honduras, Nicaragua, Panama.

Hosts.- Schedl (1962) lists 122 host species. To his list are added: Anacardium excelsum, Astronium graveolens, Brownia sp., Bursera simarubra, Cedrela mexicana, Dendropanax arboreum, Enterolobium sp., Eschweilera, Ficus sp., Inga alba, Jacaranda copaia, Melicoccous bijugata, Pinus oocarpa, Pouteria egregia, P. guianensis, Terminalia amazonia, Theobroma cacao, and Vismia sp.

Biology.- The habits of this species are evidently very similar to those of ferrugineus and affinis, although this species apparently is more successful in slightly drier habitats. The deep tunnels appear very similar to those of ferrugineus and affinis; however, the surface tunnels seen on wood from which the bark has been peeled are never present.

Notes.- The above treatment was based on the study of the three identical female syntypes of volvulus in the Kiel material of the Fabricius collection in the Copenhagen Museum, on the holotypes of hubbardi, schwarzi, rileyi, grenadensis, and vagabundus, on syntypes of alternans and torquatus, on Eggers and Sched homotypes of badius, and on 829 other specimens. The third syntype of volvulus is here designated as the lectotype of Bostrichus volvulus Fabricius, and the second syntype in the Chapuis collection is here designated as the lectotype of torquatus.

Originally this species apparently existed as two distinct geographical forms. The northern race occurred from the northern half of Mexico to Florida and Cuba, the southern race in Central and South America. The northern race is more slender, the strial punctures are smaller and more widely spaced, and the interstriae are flat. In the southern race the body form is slightly stouter, the discal striae are weakly impressed, the strial punctures are slightly larger, deeper, and closer. Through modern commerce
one or both forms have been spread throughout the tropical regions of the world and into the original territories of one another. The result has been that in most areas one or both forms may exist, but in other areas some or all of the population may be intermediate between the two. Although subspecific names might have been appropriate at one time, they now appear impractical even though a majority of the specimens from many areas can be distinguished on a morphological basis.

Specimens compared by Blandford to the type of interstitialis are rather small specimens of volvulus of the northern race in which the interstriae are almost impunctate. If Blandford's identification was accurate, then interstitialis is a junior synonym of volvulus.

## 67. Xyleborus morulus Blandford

Xyleborus morulus Blandford, 1898, Biol. Centr. Amer., Coleopt. $4(6): 212$ (Holotype, female; Costa Rica: British Mus. Nat. Hist.)
Diagnosis.- This species is distinguished from volvulus (Fabricius) as indicated in the following description.

Female. - Length $2.7-2.9 \mathrm{~mm}, 2.9$ times as long as wide; color very dark brown to black.

Exactly like northern race of volvulus except averaging larger, much darker in color, and with basal-most socketed tooth on lateral margin of anterior tibia not noticeably separated from others, occurring at $200-1500 \mathrm{~m}$ in elevation.

Distribution.- Michoacán and Guatemala to Costa Rica.

MEXICO: Michoacán: Patuan, 1-XI-80, 1300 m , Spondias mombin, T. H. Atkinson. GUATEMALA: Palín, Esquintla, 19-V-64, 300 m , No. 590, Bursera; Rodeo, Esquintla, 4-VI-64, 200 m , No. 676, tree branch. COSTA RICA: Santa Ana, San José, 9-X-63, 1300 m, No. 227, log; San Ignacio de Acosta, San José, 5-VII-63, 1500 m, No. 30, Erythrina costaricensis; San José, San José, 22-X-63, 1300 m , No. 174, E. costaricensis: Tapanti, Cartago, 17-VIII-63, 1300 m , No. 104, E. costaricensis; all were taken by me.

Hosts.- Bursera sp., Erythrina costaricensis, etc.

Brology.- The habits apparently are as in volvulus except that this species occurs at higher elevations, $200-1500 \mathrm{~m}$.

Notes.- The above treatment was based on the holotype and on 31 other specimens. Except for the apparent hybridization of races in volvulus and the sympatry of its
southern race with morulus, morulus might be considered a geographical race of the almost identical northern race of volvulus. Under existing circumstances there is no alternative to full species status for morulus.

## 68. Xyleborus planicollis Zimmermann

Xyleborus planicollis Zimmermann, 1868, Trans. Amer. Ent. Soc. 2:145 (Holotype, female; Pennsylvania; Mus. Comp. Zool., 984)
Diagnosis.- The head, pronotum, and elytral disc are as in ciduus Eichhoff, except for slight deviations cited below; the declivity is almost identical to xylographus (Say) except it is not as steep and the strial punctures are smaller and have their interiors smooth and shining.

Female.- Length 2.3-2.4 mm, 2.7 times as long as wide; color reddish brown.

Head, pronotum, and elytral disc as in viduus except pronotal impression not as strong, somewhat less extensive, punctures slightly smaller, hair in anterolateral areas finer, not as long; interstrial setae on elytral dise finer. Elytral declivity occupying 33 percent of elytral length, not as steep but more broadly flattened than in xylographus, surface reticulate-granulate about as in xylographus; strial punctures very small, weakly impressed, their interiors smooth, brightly shining; interstriae 2 feebly impressed, 1 as high as 3, 1-3 each with a row of fine granules; declivital vestiture as on disc, rows of setae on all interstriae, as long as on disc.

Distribution.- Missouri and Pennsylvania.

USA: Indiana: W. Lafayette, 10-VII-81, trap, M. Deyrup. Missouri: 10 miles E Salem, Dent Co., 19-VII-77, \#28, M. P. Roling. Pennsylvania: Pen Mar, 2-VIII, Hubbard and Schwarz.

Notes.- Although the holotype of planicollis was examined, it was thought to be a male of xylographus; appropriate specimens were not then available for comparison. Bright (1968:1313) reached the same erroneous conclusion. When males of xylographus were available and the female of viduus was dissected, it became apparent that the holotype of planicollis is actually a female of a very distinctive species closely allied to viduus. Three specimens were examined.

## 69. Xyleborus viduus Eichhoff

Xyleborus ciduus Eichhoff, 1878, Mém. Soc. Roy. Sci. Liége (2)8:391 (Holotype, female; type locality uncertain, Brazil? or America septentrionali; apparently lost with Hamburg Mus.)
Diagnosis.- This unique, rare species is distinguished by characters of the pronotum and elytral declivity as described below and in the above key.

Female. - Length 2.0-2.5 mm, 2.7 times as long as wide; color reddish brown.

Frons essentially as in rylographus (Say).
Pronotum 1.14 times as long as wide; widest near middle, sides moderately arcuate on basal two-thirds, strongly, somewhat narrowly procurved in front; anterior slope extending to basal third, devoid of asperities, median half just anterior to middle somewhat flattened, this impression becoming a broad, shallow sulcus and extending to base on median fourth; surface smooth, brightly shining, punctures rather coarse, close, extending from base to anterior margin, those on anterior fourth smaller. Glabrous on basal third, median two-thirds of anterior areas with numerous, recumbent, short, rather stout hair, lateral areas with very long, rather coarse hair.

Elytra 1.7 times as long as wide, 1.6 times as long as pronotum; disc as in xylographus except strial and interstrial punctures distinctly larger; deeper. Declivity occupying 38 percent of elytral length, very strongly sulcate on median half; striae 1 and 2 distinctly punctured to apex; interstriae 1 unarmed, its profile straight, 2 unarmed, ascending slightly laterally, 3 rather strongly elevated, armed by two coarse tubercles, 1 one-fourth declivital length from base, 2 at middle, one or two smaller tubercles on basal fourth and on apical fourth. Vestiture consisting of rows of interstrial hair to base, each slightly longer than distance between rows and between setae within a row.

Distribution.- Missouri to Maryland and Florida.

USA: Alabama: Corona Mine near Oakman, 18-1N-76. Plot 75-5-T, B. A. Hawkins. Florida: Ocala, Marion Co., 21-5 to 9-VII-77, blacklight, M. C. Thomas. Maryland: Glen Echo, I2-V1I-22, L. L. Buchanan. Missouri: Dent Co., 23-VIII-73, window trap, M. P. Roling. Tennessee: "Ten," Hubbard and Schwarz.

Notes. - The identification of this species was based on the original description and on

10 specimens. Although specimens appear to be males, due to the "abnormal" pronotum, dissection has proven them to be females. The "male" type apparently is lost and no authentic specimens could be located. It is exceedingly rare, but apparently breeds in broadleaf trees.

## 70. Xyleborus xylographus (Say) <br> Fig. 190

Bostrichus xylographus Say, 1826, Acad. Nat. Sci. Philadelphia 5(2):256 (Presumably eastern USA, type data not published; type series lost): Bright, 1968 , Canadian Ent. 100:1313 (Neotype, female; North Carolina; Canadian Nat. Coll., 9518)
Xyleborus xylographus: Zimmermann, I868, Trans. Amer. Ent. Soc. 2:145
Vyleborus inermis Eichhoff, 1868, Berliner Ent. Zeitschr. 11:401 (Syntypes?, female: Cuba; presumably lost with Hamburg Mus.); Eichhoff, 1878, Mém. Soc. Roy. Liége (2)8:370. Synonymy
Nylchorus canadensis Swaine, 1917. Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(1):24 (Lectotype, female; Ile Perrot, Quebec: Canadian Nat. Coll., designated by Bright, 1967, Canadian Ent. 99:680): Wood, 1957, Canadian Ent. 89:403. Synonymy
Diagnosis.- This species is distinguished from pubescens Zimmermann by the slightly stouter body form, by the more broadly convex elytral declivity, by the minutely rugosereticulate, dull, declivital surface, and by the smaller declivital tubercles.

Female. - Length 2.3-2.7 mm, 2.8 times as long as wide; color reddish brown.

Frons and pronotum essentially as in ferrugineus except punctures on pronotal disc distinctly larger, discal surface usually obscurely reticulate.

Elytra 1.6-1.7 times as long as wide, 1.4 times as long as pronotum; disc occupying basal two-thirds; sides almost straight and parallel on basal two-thirds, broadly rounded to obtusely subangulate behind; striae not impressed, punctures small, shallow; interstriae almost smooth, shining, three to four times as wide as striae, punctures uniseriate, shallow, distinctly smaller than those of striae. Declivity steep, very broadly convex; surface dull, finely rugose-reticulate; strial punctures distinctly larger than on disc, very shallow, each surrounded by a small, smooth, shining area; interstriae 1 and 3 each armed by about four widely spaced, small, blunt tubercles, a few
smaller tubercles in lateral areas; posterolateral margin rounded, its crest unarmed. Minute strial setae almost obsolete; vestiture consisting of interstrial rows of rather coarse, erect setae, each seta about as long as distance between rows and between setae within a row.

Male.- Length 1.9 mm ; head and elytra essentially as in female except all characters imperfectly formed; pronotum about as in affinis except concave area less strongly impressed, anterior margin obtusely produced and without a median tubercle.

Distribution. - Minnesota and New Hampshire to Texas and Florida; California?, and Cuba.

CANADA: Ontario: "E Ont." Quebec: 1 sle Perrot. USA: Arkansas: Washington Co. California: China Flat, Eldorado Co., 28-V1-45, L. W. Quate (one specimen, introduction or labeling error?). District of Columbia: Washington. Florida: Gainesville, Key West. Georgia:

Demorest. Illinois: Macomb, Monroe Co. Indiana: Perry Co. Iowa: Ames, Columbus, Iowa City. Maine: Portland. Maryland: Beltssille, Bladensburg, Plummers 1sland, Travilah. Massachusetts: Andover, Boston. Chicobee. Framingham. Michigan: Alma, Detroit. Minnesota: Hennepin Co.. Houston Co.. Redwing. Washington Co. Missouri: Salem. New Hampshire: Webster. New Jersey: Boonton, Browns Mills Junction, Palisades, Ramsey. New York: Huntington on Long Island, Ithaca, New York, Olcott, West Point. North Carolina: Tryon. Ohio: Columbus. Pennsylvania: Blair Co.. Highspire, Pen Mar. South Carolina: Mt. Rest, Lumber. Texas: Liberty: Virginia: Falls Church, Mt. Vernon. Portsmouth. West Virginia: Bayard, Cantwell, Kanawha Station, Little Falls, Morgantown, Wood Co. Wisconsin: Beaver Dam. Buffalo Co., Clintonville, Madison, Middleton.

Hosts.- Quercus spp., rare in other trees.
Biology. - The literature treating the name xylographus is so confused that it is uncertain which, if any, references actually refer to this species. The habits probably are similar to those of colculus.

Fig. 190. Kyleborus spp., female declivities: a, xylographus; b, affinis: c, pubescens. (After Bright 1976:133.)

Notes.- The above treatment was based on the neotype of xylographus, on the supposed syntypes of inermis sent by Eichhoff to Schwarz and now in the U.S. National Museum, on 7 supposed syntypes of inermis in the Chapuis Collection, on the lectotype of canadensis, and on 132 other specimens. Most of the literature treating xylographus actually refers to Xyleborinus saxeseni (Ratzeburg), which was thought to be the male of this species for many years. The "syntypes" of inermis in the Chapuis Collection are labeled as from Brazil, Santa Catherina, West Indies, and Boreal America; because most of them are obviously mislabeled and because none of them are from Cuba, they are not recognized here as syntypes.

## 71. Xyleborus californicus Wood

Xyleborus californicus Wood, 1975, Great Basin Nat. 35:399. (Holotype, female; Stanford University, Palo Alto, California; California Acad. Sci.)
Diagnosis.- This species almost certainly was introduced into California from another area. It might be confused with pubescens Zimmermann, but it is distinguished by the smaller size, by the more abundant pubescence, and by the reticulate-granulate interiors of the strial punctures on the declivity. Allied species occur in southeast Asia and South America.

Female.- Length $2.0-2.2 \mathrm{~mm}, 2.9$ times as long as wide; color yellowish brown.

Frons rather strongly convex; surface strongly reticulate, a few small granules from epistoma to upper level of eyes. Vestiture of fine, sparse hair.

Pronotum 1.2 times as long as wide; sides almost straight and parallel on basal twothirds, rather broadly rounded in front; anterior margin unarmed; summit in front of middle; anterior slope steep, rather coarsely asperate; posterior areas strongly reticulate, punctures small, shallow, rather close. Vestiture of fine, short, rather abundant hair.

Elytra 1.7 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal two-thirds, broadly rounded behind; dise occupying basal three-fourths; striae not impressed, punctures small, shallow, distinct, in rows, spaced by diameter of a puncture; interstriae three to four times as
wide as striae, almost smooth, shining, punctures fine, in indefinite rows in some specimens, distinctly confused on basal half in others. Declivity steep, convex, general contours as in pubescens; strial punctures large, shallow, distinct, their interior surfaces reti-culate-granulate; interstriae only slightly wider than striae, their punctures mostly replaced by minute granules on all interstriae, a few granules on 1, 3, and lateral areas; posterolateral margin rounded, with an indefinite row of scattered granules. Vestiture of rather abundant, short, fine hair, distinctly longer on margins of declivity.

Distribution.- California to Oregon.
USA: California: Knight's Landing in Yolo Co., 10-X49, at light, J. R. Fowler; Stanford University, 15-25-1II44, C. D. Duncan. Oregon: St. Paul, Marion Co., 28-1V80, trap, D. Overhulser.

Notes. - The above treatment was based on the type series of seven specimens. The localized distribution of this species in an urban area near a major port strongly suggests that it was introduced from another area.

## 72. Xyleborus pubescens Zimmermann Fig. 190

Xyleborus pini Say (??): Eichhoff, 1868, Berliner Ent. Zeitschr. 11:401 (Erroneous identification)
Xyleborus pubescens Zimmermann, 1868, Trans. Amer. Ent. Soc. 2:145 Lectotype, female; Southern States; Mus. Comp. Zool., 986, designated by Wood, 1973, Great Basin Nat. 33:187); Schedl, 1952, Ent. Blätt. 47-48:163 (Synonym of pini of Eichhoff)
Nyleborus propinguus Eichhoff, 1869, Berliner Ent. Zeitschr. 12:281 (Lectotype, female; Amerique boreali; Brussels Mus., designated by Wood, 1973, Great Basin Nat. 33:187). Synonymy
Diagnosis.- This species is distinguished from the northern race of volvulus (Fabricius) by the more coarsely punctured pronotal dise that has fine lines radiating from most of these punctures, by the larger strial punctures on the disc, by the finer declivital tubercles, and by the rounded posterolateral margin of the elytral declivity, its crest rounded and unarmed. It is distinguished from the more closely related xylographus (Say) by characters mentioned in the diagnosis of that species.

Female.- Length 2.3-2.7 mm, 2.9 times as long as wide; color reddish brown.

Frons and pronotum as in xylographus.

Elytra 1.7 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal two-thirds, then slightly tapered, rather broadly rounded behind; dise confined to basal two-thirds; striae not impressed, punctures rather coarse; interstriae less than twice as wide as striae, almost smooth, shining, punctures rather fine, uniseriate. Declivity steep, rather narrowly convex; surface smooth, shining; strial punctures slightly larger than on disc, very shallow, interstriae 2 unarmed, punctures almost obsolete, 1 and 3 each armed by about three to five fine, pointed granules, lateral areas with a few similar granules; posterolateral margin rounded, its crest unarmed (except for usual fine granules on interstriae 3 and 4). Vestiture as in xylographus.

Distribution.- Ontario to Texas and Florida.

CANADA: Ontario: Queenston. USA: Alabama: Birmingham. Arkansas: Hope, Hot Springs N.P. District of Columbia: Washington. Florida: Crescent, Dade Co., Duval, Enterprise, Gainesville, Lake Lucy, Marion Co., Oak Hill, Paradise Key, Royal Palms St. Pk., Tampa. Georgia: Atlanta, Clarke Co., Clyo, Demorest, Waycross. Kentucky: Morehead. Louisiana: Bogalusa, Tallulah. Maryland: Bladensburg, College Park, Travilah. Mississippi: Laurel, Ocean Springs. New Jersey: Fivemile Beach, New Lisbon, Orange Mtn. New York: Woodbury. North Carolina: Asheville, Biltmore, Southern Pines, Tryon. Pennsylvania: Angora, Laurel. South Carolina: Aiken, Clemson, Florence, Myrtle Beach, North Landing, Poinsett St. Pk. Texas: Bastrop, Call, Coldspring, Fedora, Nacogdoches. Virginia: Chase City, Falls Church, Ft. Monroe, Nelson Co. West Virginia: Kanawha Station, Roosevelt.
Hosts.-Pinus echinata, P. palustris, $P$. spp.

Biology.- Probably similar to volvulus. It is attracted to light in large numbers in pine woods. Due to the taxonomic confusion of species, early references to this name are not reliable.

Notes.- Eichhoff (1868) described this species under the questioned name Xyleborus pini Say. When it was recognized that Say's species belonged to a different genus, subsequent authors listed this species as Xyleborus pini Eichhoff, although this name has never been properly described. Article 49 of the International Code of Zoological Nomenclature invalidates names based on misidentification. For this reason, the oldest available name for this species, pubescens Zimmermann, must be used. Two syntypes of
pubescens, a supposed cotype of "pini," the lectotype of propinguus, and 373 other specimens were examined.

## 73. Xyleborus intrusus Blandford

Xylehorus intrusus Blandford, 1898, Biol. Centr. Amer., Coleopt. 4(6):213 (Lectotype, female: San Geronimo. Guatemala; British Mus. Nat. Hist., present designation)
Xylehorus howardi Hopkins, 1915, U.S. Dept. Agric. Rept. 99:65 Holotype female; Washington, D.C.: U.S. Nat. Mus., 7412): Wood, 1972, Great Basin Nat. 32:198. Synonymy
Xylchorus fitchi Hopkins, 1915, U.S. Dept. Agric. Rept. 99:66 (Holotype, female; Hyslop, Long Island, New York: (U.S. Nat. Mus., i413): Bright, 1968, Canadian Ent. 100:1315. Synonymy
Xyleborus scopulorum Hopkins. 1915, U.S. Dept. Agric. Rept. 99:66 (Holotype, female; Black Hills. South Dakota; U.S. Nat. Mus., 7414); Wood, 1972, Great Basin Nat. 32:198. Synonymy
Diagnosis.- This species is distinguished from pubescens Zimmermann by the smaller strial punctures, by the larger declivital tubercles, and by the steeper declivity.

Female. - Length 2.2-2.7 mm, 2.9 times as long as wide; dark reddish brown.

Frons and pronotum essentially as in ferrugineus (Fabricius) except punctures in posterior area slightly larger; surface of posterior area partly or mostly reticulate or subreticulate, smooth areas usually with minute lines or impressed points.

Elytra 1.7 times as long as wide, 1.5 times as long as pronotum; disc confined to slightly more than basal two-thirds; striae feebly if at all impressed, punctures small, shallow; interstriae smooth, shining, two to three times as wide as striae, punctures fine and coarse, more or less alternating, uniseriate. Declivity very steep, rather strongly convex; strial punctures about as on disc; interstriae 2 feebly impressed, unarmed or with one or two small granules near base, punctures reduced, many obsolete, 1 and 3 each armed by three to six rather coarse tubercles, each as high as wide, lateral areas with a few similar small tubercles; posterolateral margin rounded, unarmed. Vestiture as in xylographus but finer, with some setae slightly longer.

Distribution.- British Columbia and New York to Honduras.

CANADA: British Columbia: Aspen Grove. USA: Arizona: Chiricahua Mts.. Flagstaff, Jacobs Lake, Pinal Mts., Prescott N.F., Williams. California: Jackson Creek in Plumas Co., Lake Mck. in Fresno Co.. Los Olivos. Mt. Laguna in Cleveland N.F.. Madera Co., Pinecrest, Santa Barhara Co., Santa Rosa, Sequoia N.F., Shasta N.F., "Sylvana." Colorado: N Cheyeme Canyon. District of Columbia: Washington. Idaho: Moscow Mlts. Maryland: Beltsville, Snow Hill. Montana: "Mont." New Mexico: Cloudcroft, Las Vegas Hot Springs, Los Alamos, Meek. North Carolina: Bent Creek. Oregon: Dever. Pennsylvania: Mt. Alto. South Carolina: Clemson. South Dakota: Pringle. Utah: Logan Canyon, Provo, Provo Canyon. Virginia: Falls Church. IIEXICO: Chiapas: 20 km SW Cintalpa. Distrito Federal: 24 km S Guarda. Durango: El Salto. Jaliseo: Volcán Colima. Mexico: Tlalmonalco, Tolnca. Morelos: Cuernavaca, Nochimilco. Oaxaca: Oaxaca. Puebla: Puebla. Texmelucan. GUATEMALA: San Geronimo. HONDURAS: Zamorano.

Hosts.- Pinus contorta, P. coulteri, P. jeffreyi, P. leiophylla, P. mexicana, P. ponderosa, and Pseudotsuga menziesii.

Biology. - This species attacks the base of recently killed, standing trees in which decay is well under way, at or near the ground level. The gallery system evidently is similar to that of volvulus.

Notes. - The above treatment was based on Blandford's three syntypes of intrusus, on the holotypes of howardi, fitchi, and scopulorum, and on 162 other specimens. The first female syntype, from San Geronimo, Guatemala, in Blandford's series is here designated as the lectotype of intrusus.

The population from the eastern United States averages slightly smaller ( $2.2-2.5 \mathrm{~mm}$ ) than those from western areas ( $2.3-2.7 \mathrm{~mm}$ ). The pronotal and elytral characters mentioned by Bright (1968) are not consistent and occur in both populations.

## 74. Xyleborus declivus Eichhoff

Xyleborus decliris Eichhoff, 1869. Berliner Ent. Zeitschr. 12:280 (Holotype, female; Teapa, Tabasco, Mexico; presumably lost with Hamburg Mus.)
Xiyleborus pseudoprocer Schedl. 1949, Rev. Brasil. Biol. 9:279 (Holotype, female: Guatemala; Schedl Coll.): Wood, 1972, Great Basin Nat. 32:197. Synonymy
Diagnosis.- This species is distinguished from procer Eichhoff by the narrower elytral declivity, which is feebly if at all impressed, and by the very minute declivital punctures. lt is less closely allied to celsus Eichhoff,
from which it is distinguished by the narrower declivity that has fewer marginal granules, and by the obsolete declivital striae.

Female.- Length 4.0-4.4 mm, 3.2 times as long as wide; color reddish brown.

Frons broadly convex; finely rugose-reticulate, with small, isolated, moderately abundant granules below, granules sparse above eyes, vestiture fine, sparse, inconspicuous.

Pronotum 1.3 times as long as wide; sides straight and parallel on basal two-thirds, rather broadly rounded in front; summit well in front of middle; rather finely asperate on anterior two-thirds; posterior areas smooth, shining, punctures very minute, sparse. Vestiture sparse, confined to margins.

Elytra 1.9 times as long as wide, 1.46 times as long as pronotum; sides almost straight and parallel on basal two-thirds, then slightly tapered, rather narrowly rounded behind; declivity confined to slightly more than basal two-thirds; striae not impressed, punctures small, shallow; interstriae smooth, shining, punctures obsolete except very sparse on 1 . Declivity rather steep, flattened on central half, otherwise convex: central half flat to feebly impressed, smooth, slightly dull, punctures fine, moderately abundant, confused, striae almost obsolete; upper and lower fourths on extreme lateral side of interstriae 1 armed by coarse, pointed tubercles positioned about as in celsus, basal and lateral areas with a few smaller tubercles; posterolateral margins rounded, unarmed. Vestiture confined to declivity and sides; consisting of rather sparse, moderately long, interstrial hair.

Distribution. - Veracruz to Costa Rica.
MEXICO: Veracruz: Lago Catemaco, 1-3-V-69. D. E. Bright. GUATEMALA: Guatemala; Las Mercedes, Zapote, and Cerro Zunil by G. C. Champion. COSTA RICA: Pandora, Limón, 23-VI11-63, 50 m , No. 135, log, No. 138, at light, S. L. Wood.

Biology. - The only available specimen not collected at light was taken from a new tunnel in a tree limb 10 cm in diameter.

Notes.-- The above treatment was based on 20 specimens, including Blandford's series from Guatemala, the holotype of pseudoprocer, and three other specimens that were compared to the Blandford and Schedl specimens.

## 75. Xyleborus macer Blandford

Xyleborus macer Blandford, 1898, Biol. Centr. Amer., Coleopt. 4(6):2IS (Lectotype, female: El Tumbador, Guatemala; British Mus. Nat. Hist., present designation)
Diagnosis. - This species is distinguished from declivis Eichhoff by the smaller size, by the larger strial punctures, and by the smaller flattened area on the declivity.

Female.- Length 2.9-3.3 mm, 3.5 times as long as wide; color reddish brown.

Frons and pronotum as in declivis Eichhoff except frons with fewer granules.

Elytra 2.1 times as long as wide, 1.4 times as long as pronotum; outline and proportions as in declicis; disc as in declivis except strial punctures distinctly larger, interstriae about twice as wide as striae; declivity as in declicis except flattened area slightly smaller, tubercles averaging very slightly smaller.

Distribution.- Veracruz to Panama and Venezuela.

MEXICO: Veracruz: Dos Amates, 3-V-69, D. E. Bright; Lago Catemaco, 4-V-69, D. E. Bright. GUATEMALA: Zapote and El Tumbador by G. C. Champion; Guatemala, 28-11I-41, primavera log, Cuyotenango, 1-II66. J. M. Campbell. NICARAGUA: Chontales, G. C. Champion. COSTA RICA: Dominical, Puntarenas, 9-XII-63, 3 m , in flight, S. L. Wood: Rincón de Osa, Pumtarenas, II-V/lII-66, 30 m , No. 76. log, S. L. Wood: Turrialba, Cartago, 1970. R. I. Cara. PANAMA: Ft. San Lorenzo, Canal Zone, $10-\mathrm{X}-57$, at light; Tolé, G. C. Champion. COLOMBIA: Anchicaya, 27-VII-70, J. 11 . Camphell. VENEZUELA: Finca Monasterios, Cacagua, Miranda, 197I, Theobroma cacao.

Hosts. - Theobroma cacao, etc.
Biology. - Specimens have been taken from logs and limbs.

Notes.- Blandford's syntypic series of six specimens and 37 other specimens were examined. The first female syntype in Blandford's series, on a double mount, from El Tumbador, Guatemala, is here designated as the lectotype of macer. This specimen has been regarded as the type for many years, but it has not previously been so designated.

## Xyleborus exaratus Blandford

Xyleborus exaratus Blandford, 1898, Biol. Centr. Amer., Coleopt. 4(6):206 (Holotype, male; Bugaba, Chiriquí, Panama: British Mus. Nat. Hist.)
Diagnosis.- This male has not been associated with any known female. It superficially resembles Xyleborus nobilus Eggers.

Male.- Length 4.5 mm , 2.4 times as long as wide; immature, color yellowish brown.

Head slightly enlarged, broad, frons convex, reticulate, punctures fine, obscure; mandibles moderately enlarged, stout. Eye reduced, entirely divided by an emargination. Antennal club moderately small, without evident sutures.

Pronotum 1.2 times as long as wide; subquadrate, sides straight and parallel on basal three-fourths, very broadly rounded in front; summit indefinite, on anterior third; anterior slope feebly declivous, asperities minute, almost obsolete on median two-thirds, fully formed only on anterolateral areas; surface almost smooth, subshining, punctures very small, moderately close. Glabrous except at margins.

Elytra 1.2 times as long as wide, 1.0 times as long as pronotum; disc occupying basal two-thirds; basal margins abrupt, precipitous; surface smooth, shining, strial punctures very small, in slightly irregular rows; interstrial punctures minute, almost obsolete, confused. Declivity abruptly, obliquely truncate; surface as on disc, very slightly convex on lower half; punctures confused except near upper margin; margin on upper half abruptly rounded, subacute on lower half. Glabrous.

Distribution.- Panama.
PANAMA: Bugaba, Chiriquí, G. C. Champion.
Notes. - The above treatment was based on the holotype. No other American species known to me resembles this one. It is in a unique species group.

## Genus XYLEBORINUS Reitter

. $y$ leborinus Reitter, 1913. Wiener Ent. Zeit. 32(Beiheft): 83 (Type-species: Bostrichus saxescni Ratzeburg, subsequent designation by Swaine. 1918. Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. I4(2):50)
Diagnosis.- This genus has been recognized by most previous authors either as a subgenus or a synonym of Xyleborus Eichhoff. Nevertheless, following a review of more than 600 species of the world fauna of Xyleborini, it is obvious that clearly recognizable subgroups exist within the tribe that should have generic status. Xyleborinus is one such group. Xylcborinus is distinguished from

Xyleborus by the precipitous basal margins of the elytra in the median area, by the conical scutellum that does not fit into the sutural notch, by the conspicuous pubescence in the sutural notch adjacent to the scutellum, and, in part, by the absence of a carina on the posterolateral margin of the declivity.

Description.- Length of females 1.4-3.5 mm , 2.6-3.0 times as long as wide; males dwarfed, deformed, stouter; color dark brown. Description as for Xyleborus except as noted in above diagnosis.

Distribution.- Worldwide; more than 30 nominate species are known; 10 species occur in North and Central America.

Biology.- The limbs and boles of dying or recently cut material are selected for attack. Basic habits are essentially as described for Xyleborus. Parental tunnels are either of the cave type (saxeseni) or branched (most other species).

Notes.- Until a world review of the Xy leborini was attempted, I opposed the recognition of Xyleborinus as anything more than a subgenus. It is now evident that it forms a clearly definable genus that is allied to several Indomalayan species groups (genera?) awaiting clarification. A reliable description of Xyleborinus cannot be made until a generic revision of the tribe is completed.

## Key to the Species of Xyleborinus

1. Interstriae 1, 2, and 3 each equally, regularly armed by a row of moderately fine, pointed tubercles; posterolateral margin of declivity rounded and bearing several somewhat larger tubercles; Veracruz to Panama and Venezuela; $1.4-1.6 \mathrm{~mm}$
Interstriae 1 and 2 unarmed except at base in some species ( 1 armed in
saxeseni), 3 variously modified .................................................................................. 2

2(1). Lateral margins of elytral declivity armed by two or three pairs of large, slen
der spines, spine 1 (often absent) at upper margin, 2 just below middle, 3 just
before apex; punctures on declivital face rather larger; $2.4-3.5 \mathrm{~mm}$ ..... 3

- $\quad$ Smaller, less than 2.3 mm ; punctures on elytral declivity in rows, armature of lateral convexity different
3(2). Larger; declivital punctures confused; declivity armed by three pairs of spines (upper pair sometimes absent); declivity distinctly concave; Costa Rica to Colombia; $3.3-3.5 \mathrm{~mm}$

5. dirus (Wood)

- Smaller; strial punctures on elytral declivity in rows; declivity armed by two pairs of spines; declivity almost flat4

4(3). Declivity more narrowly, subconcavely impressed, major spines smaller, apparently blunt, minor spines on basal half smaller; declivity steeper, shorter; El Salvador; Quercus; 2.5 mm (see also 2. tribuloides Wood)

- Declivity more broadly impressed, transversely almost flat, major spines conspicuously larger, minor spines on basal half much smaller; declivity more gradual, longer; Panama; $2.4-2.5 \mathrm{~mm}$

4. tribulosus Wood

5(2). Lateral margins of declivity strongly, obtusely elevated from sutural apex to well above middle of declivity, summit and lateral areas unarmed or with very minute granules; Costa Rica; $1.6-1.7 \mathrm{~mm}$ 6. protinus (Wood)

- Lateral margins of declivity and lateral areas armed by several rather large, sharply pointed tubercles6

6(5). Interstriae 3 armed throughout length of declivity by a row of about eight large, closely set teeth, lateral areas bearing 20 or more similar but smaller teeth; Costa Rica and Panama to Venezuela and Surinam; 1.9-2.2 mm
7. reconditus (Schedl)

7(6). Declivity occupying posterior two-thirds of elytral length, broadly, moderately concave; interstriae 3 armed near middle of declivity by a rather large spine, base and sides of declivity bearing 20 or more smaller denticles of various sizes; Costa Rica to Colombia; 1.9-2.3 mm
8. bicornatulus (Wood)

- Elytral declivity shorter, rather steep, occupying less than one-third of declivital length; declivity devoid of a large spine 8
8(7). Declivital interstriae 1 and 3 equally, weakly elevated; interstriae 3, 4, basal half of 1 , and lateral areas with a few small pointed granules, ventrolateral areas weakly elevated; S Canada and United States, etc.; 1.9-2.4 mm

9. saxeseni (Ratzeburg)

- Declivital interstriae 1 not elevated or armed by granules, ventrolateral area rather strongly elevated and armed by 15-20 denticles, one or two of those near apex of interstriae 3 often moderately large; S Florida, Costa Rica to Colombia and Venezuela; 1.6-1.9 mm

10. aspericauda (Eggers)

## 1. Xyleborinus intersetosus (Blandford)

Xyleborus intersetosus Blandford, 1898, Biol. Centr. Amer., Coleopt. 4(6):2II (Holotype, female; Tamahú, Vera Paz, Guatemala; British Mus. Nat. Hist.)
Xyleborus analogus Schedl, 1949, Rev. Brasil. Biol. 9:277 (Holotype, female: Mexico: Eggers Coll., evidently on loan to Sched)); Wood, 1966. Great Bain Nat. 26:31. Synonymy
Diagnosis.- This species is distinguished from other Central American representatives of the genus by the broadly convex elytral declivity, by the equally, uniformly tuberculate declivital interstriae, and by the small size.

Female.- Length $1.4-1.6 \mathrm{~mm}, 2.8$ times as long as wide; color dark brown.

Frons broadly convex; surface reticulate, a few coarse, shallow punctures; vestiture of sparse, inconspicuous hair.

Pronotum 1.1 times as long as wide; widest slightly behind middle, sides very weakly arcuate on more than basal half, rather narrowly rounded in front, anterior margin armed by about six to eight broad, low, poorly formed serrations; summit at middle; anterior slope rather coarsely asperate; posterior areas reticulate, punctures fine, rather close. Vestiture hairlike, sparse on disc, mostly confined to marginal areas.

Elytra 1.6 times as long as wide, 1.4 times as long as pronotum; sides straight and parallel on slightly more than basal half, then very slightly tapered, rather broadly rounded behind; disc confined to slightly more than basal half; basal margins and scutellum as
described for genus; striae not impressed, punctures minute; spaced within a row by two to four diameters of a puncture; interstriae smooth, shining, about five times as wide as striae, punctures very slightly smaller than those of striae. Declivity moderately steep, broadly convex; striae feebly impressed, punctures often slightly larger than on disc; interstriae each with a row of about six to eight small pointed tubercles of equal size; posterolateral margin rather narrowly rounded. Vestiture of rows of semirecumbent, moderately long strial hair, and rows of erect, coarser, longer interstrial bristles; each bristle slightly longer than distance between rows or between bristles within a row.

Male.- Length 1.0 mm ; essentially as in female except dwarfed, all characters poorly formed; anterior slope of pronotum less precipitous, most asperities obsolete; elytral declivity longer, more gradual, tubercles minute to obsolete.

Distribution. - Veracruz to Colombia and Venezuela.
MExico: Chiapas: Palenque Ruins, 9-V-69, D. E. Bright. Veracruz: Dos Amates, 5-V-69, D. E. Bright; Valle Nacional. GUatemala: Tamahú. Alta Verapaz. G. C. Champion. COSTA RICA: Rio Damitas, Dota Mts., San José, 12-VIII-63, 250 m , No. 124 from tree stump, No. 126 from a liana, No. 127 from Vismia guianensis, S. L. Wood; Finca Gromaco on Río Coto Brus, Puntarenas, 14-VII-63, 500 m , No. 69, tree seedling, S . L. Wood; Volcán, Puntarenas, Il-XII-63, 1000 m , No. 308, tree limb, S. L. Wood; Finca La Lola, Limón, 22-V1-63, Theobroma cacao, J. L. Saunders; Guápiles, Limón, 22-VIII-66, 100 m , No. 124, liana, S. L. Wood. PANAMA: Barro Colorado 1sland, Canal Zone. 23-Vil66. No. 31, log, S. L. Wood; $13 \mathrm{~km} \mathrm{~S} \mathrm{El} \mathrm{Hato} \mathrm{del} \mathrm{Volcán}$.

7-I-64, 1000 m , tree sapling, S. L. Wood. OTHER COUNTRIES: Colombia, Venezuela.

Hosts.- Alexa imperatricia, Sloanea multiflora, Theobroma cacao, Vismia guianensis, etc.

Biology.-Cut, weakened, and dying limbs, boles, logs, and stumps larger than 8 cm in diameter were selected for attack. The tunnels appeared to be of a simple branching type.

Notes. - The above treatment was based on 94 specimens including several that were compared by me directly to the holotypes of intersetosus and analogus.

## 2. Xyleborinus tribuloides Wood

Xylehorinus tribuloides Wood, 1977, Great Basin Nat. 37:218 (Holotype, female; 15 miles or 24 km S Valle Nacional, Oaxaca, Mexico; Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from bicornatulus Wood by the uniformly reticulate pronotum and by the much shorter, less strongly impressed, very different declivity as described below.

Female.- Length 2.1-2.3 mm, 2.9 times as long as wide; color dark brown.

Frons and pronotum about as in bicornatulus except pronotal dise uniformly, strongly reticulate.

Elytra 1.7 times as long as wide, 1.5 times as long as pronotum; declivity confined to posterior third; striae not impressed, punctures fine, shallow; interstriae smooth, shining, three to four times as wide as striae, punctures finely granulate. Declivity gradual, shallowly subconcave; punctures on striae 1 and 2 slightly larger than on dise; interstriae 1 and 2 marmed except for small granules at base, 3 armed one-third declivital length from base by a moderately coarse, pointed tubercle, as high as wide, a larger, blunt spine two-thirds of declivital length from base, longer than wide, its length about equal to width of an interstriae, a small tubercle at base above spine 1 and another at apex below spine 2 ; lateral summit at striae 4 , lateral areas armed by about a dozen moderately coarse tubercles (smaller and less numerous than in bicornatulus). Vestiture of minute strial hair and distinctly longer interstrial hair, regularly, closely spaced to base, each
interstrial seta about equal in length to width of an interstriae.

Distribution.- Oaxaca.
MEXICO: Oaxaca: 24 km S Valle Nacional, 20-V-71, Cecropia leaf petiole, D. E. Bright.

Notes.- The above treatment was based on the type series of two specimens.

## 3. Xyleborinus gracilicornis (Schedl)

Xyleborus gracilicornis Schedl, 1977, Zeitschr. Arb. Österr. Ent. 29:45 (Holotype, female; San Francisco Colera, El Salvador: Schedl Coll.)
Diagnosis.- This species is distinguished from tribulosus Wood as indicated in the above key.

Female.- Length $2.5 \mathrm{~mm}, 2.9$ times as long as wide; color dark brown.

Refer to the above key and to the original description to distinguish this species.

Distribution.- El Salvador.
EL SALVADOR: San Francisco Golera, 7-V1-74, Quercus, H. Schmutzenhofer.

Notes. - Prior to its description the holotype was examined and used in the preparation of the key.

## 4. Ayleborinus tribulosus Wood

Xyleborinus tribulosus Wood, 1972, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):41 (Holotype, female; Madden Forest, Canal Zone Panama; Wood Coll.)
Diagnosis.- This species is distinguished from dirus (Wood) by the larger size, by the more slender body form, by the smaller, uniseriate strial and interstrial punctures on dise and declivity, and by the different elytral declivity.

Female. - Length $2.4-2.5 \mathrm{~mm}, 2.8$ times as long as wide; color very dark brown.

Frons and pronotum essentially as in dirus except pronotum 1.1 times as long as wide; pronotal disc glabrous.

Elytra 1.6 times as long as wide (spines excluded), 1.4 times as long as pronotum; outline essentially as in dirus; striae not impressed, punctures small, uniseriate, close; interstriae smooth, shining, slightly more than twice as wide as striae, punctures half as large as those of striae, uniseriate. Declivity occupying two-thirds of elytral length: broadly flattened to feebly impressed, its margin armed by about 24 rather coarse, pointed denticles on interstriae 1-6 from base
to near sutural apex; interstriae 3 armed at middle and near apex by two pairs of very large spines, each spine one and one-half times as long as its basal width, about equal in length to discal distance from suture to striae 3; face of declivity with strial punctures in rows, slightly larger than on dise, interstrial punctures largely obsolete. Vestiture of rows of rather coarse interstrial setae, on disc each seta about as long as distance between rows, distinctly closer within a row, on declivity distinctly longer and less regularly placed.

Distribution.- Panama.
Panalia: Madden Forest, Canal Zone, 2-1-64, 70 m , No. 367, tree limb, S. L. Wood.

Biology.-Specimens were taken from a broken branch 8 cm in diameter.

Notes.- The above treatment was based on the type series of two specimens.

## 5. Xyleborinus dirus (Wood)

Xyleborus dirus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):41 (Holotype, female; Rincón de Osa, Puntarenas, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished by the large size, by the very coarse declivital spines that superficially resemble Xyleborus ferox Blandford, and by the confused punctures on the declivital face.

Female.- Length $3.4-3.6 \mathrm{~mm}, 2.7$ times as long as wide; mature color black.

Frons convex, epistoma slightly elevated; surface reticulate, punctures rather large, impressed, indefinite; vestiture inconspicuous.

Pronotum 1.06 times as long as wide, widest a third of its length from base; sides rather weakly arcuate on basal two-thirds, converging very slightly, then rather strongly rounded in front, median area rather narrowly produced but unarmed (in many paratypes anterior margin rather broadly rounded); summit very slightly in front of middle; posterior area reticulate, except indistinctly so near base, punctures small, distinct, rather close; vestiture rather long and abundant on sides and in asperate area.

Elytra 1.6 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal half, then arcuately converging to apex of ventrolateral declivital spine, rather broadly $U$-shaped between
spines; striae 1 weakly, others not impressed, punctures moderately large, deep, somewhat confused on 1 ; interstriae mostly twice as wide as striae, punctures similar to those of striae but deeper, uniseriate except partly confused on 1 and 2. Declivity moderately steep, broadly, shallowly excavated, lateral margins armed by three pairs of major spines; spine 1 at upper margin in line with striae 2 , spine 2 on lateral margin two-thirds declivital length from upper margin, spine 3 at ventrolateral margin; spine 1 slightly more than half as long as 3, 2 slightly smaller than 3,2 equal in length to width of antennal club; one minor tooth in front of spine 1 , two others between 1 and 2 ; declivital face with confused punctures similar to those on disc. Vestiture consisting of rather long, slender hair arising from interstrial punctures on disc and sides, setae minute on excavated area.

Male.- Length 2.5-2.7 mm; similar to female except smaller, eye reduced, pronotum not strongly arched with asperities somewhat reduced; elytral declivity much longer, more gradual, with spine 1 greatly reduced, minor teeth mostly absent.

Distribution.- Costa Rica and Colombia.
COSTA RICA: Rincon de Osa, Puntarenas, 11-VIII$66,30 \mathrm{~m}$, No. 88 , tree limb, S. L. Wood; Río Damitas, Dota Mits., San Joé, 22-VII-63, 250 m , No. 88, tree stump, No. 65, liana, S. L. Wood. COLOMBIA: Campamento Capote, 27 km NE Montoya, Santander, 2-VII$70,150 \mathrm{~m}$, No. 632, Cespedesia macrophylla, S. L. Wood.

Biology.- Specimens were taken from a standing bole 15 cm in diameter and from a stump 25 cm in diameter. The galleries were of a branching type except that some of the ends were enlarged into tabular cavities.

Notes.- The above treatment was based on the type series of 56 specimens and on one other specimen.

## 6. Xyleborinus protinus (Wood)

Xyleborus protinus Wood, 1972, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):42 (Holotype, female; Finca La Lola, Limón, Costa Rica; Wood Coll.)
Diagnosis.- This species differs from other North and Central American representatives of the genus by the broadly, shallowly concave elytral declivity, with the lateral margins unarmed.

Female.- Length $1.6-1.7 \mathrm{~mm}, 2.7$ times as long as wide; color rather light brown, the prothorax distinctly lighter.

Frons very weakly convex from upper level of eyes to epistomal margin; surface reticulate, rather coarsely, obscurely punctured; vestiture inconspicuous.

Pronotum 1.25 times as long as wide; widest one-third pronotum length from base, sides weakly arcuate, basal and anterior angles more strongly rounded, rather narrowly rounded in front; asperities fine, largely isolated; summit indefinite, in front of middle; surface reticulate in front of summit, mostly smooth and brightly shining behind, punctures small, deep, not close; vestiture largely confined to sides and asperate area.
Elytra 1.6 times as long as wide, 1.3 times as long as pronotum; sides essentially straight and parallel on basal three-fourths, then rather abruptly rounded, shallowly emarginate on median third behind; scutellum conical; striae not impressed, punctures small, deep; interstriae twice as wide as striae, punctures small, indefinite; elytra arched from base to apex. Declivity beginning on basal third of elytra, gradual; lateral margins on lower half gradually elevated and continuing almost to apex, elevation rather high, not at all acute, evidently entirely unarmed; lower half transversely concave; striae 1 and 2 with punctures larger than on disc, strongly impressed; interstriae 2 wider than 1 ; interstrial punctures obscure. Vestiture consisting of stout, hairlike setae, more abundant on declivity, particularly on inner slope of lateral elevation.

Distribution.- Costa Rica.
costa rica: Finca La Lola, Limón, 7-II-63, Theobroma cacao, J. L. Saunders.

Notes.- The above treatment was based on the type series of five specimens.

## 7. Xyleborinus reconditus (Schedl)

Xyleborus reconditus Schedl, 1963, Studies on the Fauna of Surinam and other Guyanas 4:60 (Holotype, female; Tambahredjo, Surinam; Schedl Coll.)
Diagnosis.- This species is distinguished from other Central American representatives of the genus by the gradual, impressed declivity, and by the row of coarse, stout denticles of equal size on declivital interstriae 3
from near the base to the apex, interstriae 2 becoming obsolete before the apex.

Female.- Length $1.9-2.2 \mathrm{~mm}, 2.6$ times as long as wide; color dark brown to almost black.

Frons broadly, weakly convex, epistoma feebly elevated; surface reticulate, rather closely, coarsely, shallowly punctured; vestiture of fine, sparse, inconspicuous hair.

Pronotum 1.1 times as long as wide; widest just behind middle, sides weakly arcuate, almost parallel on basal two-thirds, rather broadly rounded in front; anterior margin irregularly, finely serrate; summit broad, slightly anterior to middle; entire surface reticulate except irregular, transverse shining area on posterior half, punctures rather fine, moderately abundant. Vestiture confined to marginal areas.

Elytra 1.45 times as long as wide, 1.3 times as long as pronotum; sides almost straight and parallel on basal three-fourths, then broadly rounded, shallowly subemarginate on median sixth behind; disc confined to slightly less than basal 40 percent; striae not impressed, punctures fine, shallow; interstriae smooth, shining, about five times as wide as striae, punctures slightly smaller than those of striae, uniseriate. Declivity gradual, shallowly, broadly sulcate; punctures on striae 1 and 2 about twice as wide as those on disc; strongly impressed, almost flat between striae 2 , interstrial punctures on 1 and 2 almost obsolete; ascending rather strongly from striae 2 to broad rounded summit between striae 3 and 5; interstriae 3 armed from near base of declivity to near sutural apex by a row of rather coarse, stout denticles of about equal size, about 10-12 denticles on each side; lateral interstriae with rows of smaller tubercles; posterolateral margin rounded. Vestiture of rows of minute strial hair, and rows of longer interstrial setae; interstrial setae on disc hairlike, rather coarse on declivity, each slightly shorter than distance between rows.

Distribution.- Costa Rica and Panama to Venezuela and Surinam.
costa rica: San Isidro del General, San José, 5-XII-6.3, 1000 m, No. 287, Eugenia jambos, S. L. Wood; Rincón de Osa, Puntarenas, 1I-VIII-66, 30 m , No. 65, liana, S. L. Wood. Panama: Ft. Clayton, Canal Zone, 22-XII-63, $30 \mathrm{~m}, \mathrm{~S}$. L. Wood. VENEZUELA: Finca Monasterio, Cacagua, 1971, Theobroma cacao.

Hosts.-Eugenia jambos, Theobroma cacao, etc.

Biology. - Specimens were taken from branches and limbs $4-10 \mathrm{~cm}$ in diameter.

Notes.- The above treatment was based on 13 specimens, one of which was compared by me to the holotype of reconditus.

## 8. Xyleborinus bicornatulus (Wood)

Xyleborus bicornatulus Wood, 1967, Great Basin Nat. 27:137 (Holotype, female; Moravia, Cartago, Costa Rica: Wood Coll.)
Diagnosis.-- This species is distinguished from reconditus (Schedl) by the much smaller denticles on declivital interstriae 3, except one just below middle of declivity that is almost twice as large as those of reconditus.

Female.- Length $2.0-2.3 \mathrm{~mm}, 2.8$ times as long as wide; color almost black.

Frons broadly, transversely convex, longitudinally straight to well above eyes, the epistoma slightly, gradually raised, surface reticulate, with rather coarse, deep, sparse punctures; vestiture inconspicuous except along epistoma. Eye finely faceted; half divided by a narrow emargination.

Pronotum 1.2 times as long as wide; widest just behind middle, sides weakly arcuate, feebly if at all converging before rather abrupt anterolateral angles, rather broadly rounded in front; anterior margin subserrate; summit at middle; posterior area smooth and shining on disc, reticulate laterally, with sparse, very fine punctures; vestiture sparse, inconspicuous.

Elytra 1.6 times as long as wide, 1.3 times as long as pronotum; sides almost straight and parallel on basal two-thirds, then broadly rounded, almost straight on median third of posterior margin, arcuate portion strongly serrate; striae not impressed, punctures very small, distinct; interstriae shining, not entirely smooth, about four or five times as wide as striae, punctures about as small as those of striae. Declivity beginning very slightly more than one-third elytral length from base, gradual, rather broadly excavated, sides moderately elevated, rounded; striae 1 and 2 wider than normal, distinctly punctured; interstriae 1 and 2 shining and uniseriately punctured, each with three or four tubercles at declivital base, 1 weakly elevated, 2 impressed; interstriae 3 somewhat elevated, upper third
armed by a row of up to five tubercles, an additional much longer spine at middle of declivity; apex of interstriae 3 near declivital margin with one or two tubercles; interstriae 4 with a row of rather coarse, pointed tubercles on upper third, 5 with a similar series on middle half, 6 and 7 with similar series on most of lower half, a few tubercles extending almost to apex. Vestiture consistinng of rows of interstrial hair, rather fine on disc and sides, stout on declivity.

Distribution.- Costa Rica to Colombia.
COSTA RICA: Finca Gromaco on Río Coto Brus, Puntarenas, 14-V'll-63, 500 m , No. 79 , palm log, S. L. Wood: Rincón de Osa, Puntarenas, II-V1Il-66, 30 m , No. 55, Oehroma, S. L. Wood; Río Damitas, Dota Mts. San José, 18-11-64, 250 m , No. 442, log, S. L. Wood; Moravia, Cartago, 11-111-64, 500 m , No. 472, $\log$, S. L. Wood; Finca La Lola, Limón, 27-X11-62, Theobroma cacao, J. L. Saunders. PANAMA: 13 km S El Hato del Volcán, Chiriquí, $7-\mathrm{I}-64,1000 \mathrm{~m}$, No. 371 , tree sapling, S. L. Wood: Cerro Campana, Cocle, 26-VII-66, tree branch, S. L. Wood. OTHER COUNTRIES: Colombia.

Hosts.- Ochroma sp., Theobroma cacao, etc.

Biology.- Specimens were taken from material $5-20 \mathrm{~cm}$ in diameter. The tunnels evidently were of a simple branching type.

## 9. Xylcborinus saxeseni (Ratzeburg)

Fig. 187

Bostrichus saxeseni Ratzeburg, 1837. Die Forst-insekten 1:167 (Syntypes, female; presumably lost with Hamburg Mus.)
Xyleborinus saxeseni: Reitter, 1913, Wiener Ent. Zeit. 32(Beiheft):8.3
Tomicus dohrni Wollaston, 1854, Insecta Maderensia, p. 290 (Syntypes, female; Madera; British Mus. Nat. Hist.); Eichhoff, 1878, Mém. Soc. Roy. Sci. Liége (2)8:362. Synonymy

Tomicus decolor Boieldieu, 1859, Ann. Soc. Ent. France (3) 7:473 (Syntypes, female; Péronne, France; Paris Mus.?): Ferrari, 1867, Die Forst- und Baumzuchtschädlichen Borkenkäfer, p. 22. Synonymy
Xyleborus angustatus Eichhoff, 1866, Berliner Ent Zeitschr. 10:278 (Syntypes, female; Volhynia, USSR; presumably lost with Hamburg Mus.); Schedl, 1964, Reichenbachia 3:313. Synonymy
Xyleborus sobrinus Eichhoff, 1875, Ann. Soc. Ent. Belgique 18:202 (Syntypes?; Japan; Brussels Mus.?); Schedl, 1964, Reichenbachia 3:313. Synonymy
Xyleborus subdepressus Rev, 1883, Rev. d'Ent. 2:142 (Syntypes, male; Lyon, France; Paris Mus.?); Bedel, 1888, Ann. Soc. Ent. France, hors serie, 6:419. Synonymy

Xyleborus quercus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:63 (Holotype, female; Baxterville, Mississippi; U.S. Nat. Mus., 764.3); Wood, 1962, Great Basin Nat. 22:79. Synonymy
Xyleborus pecanus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:63 (Holotype, female; Waynesboro, Mississippi; U.S. Nat. Mus. 7645); Wood, 1962, Great Basin Nat. 22:79. Synonymy
Xyleborus floridensis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:63 (Holotype, female; Enterprise, Florida; U.S. Nat. Mus., 7646); Wood, 1962, Great Basin Nat. 22:79. Synonymy
Xyleborus arbuti Hopkins, 1915, U.S. Dept. Agric. Rept. 99:64 (Holotype, female; Walker, California; U.S. Nat. Mus., 9583); Wood, 1957, Canadian Ent. 89:403. Synonymy
Xyleborinus tsugae Swaine, 1934, Canadian Ent. 66:204 (Holotype, female; Mission, British Columbia; Canadian Nat. Coll., 3815); Wood, 1957, Canadian Ent. 89:403. Synonymy
Xyleborinus libocedri Swaine, 1934, Canadian Ent. 66:205 (Holotype, female; Oak Ridge, Oregon; Canadian Nat. Coll., 3816); Wood, 1957, Canadian Ent. 89:403. Synonymy
Xyleborus pseudoangustatus Schedl, 1949, Proc. Roy. Soc. Queensland 60:28 (Syntypes, female; Australia; British Mus. Nat. Hist. and Schedl Coll.); Schedl, 1964, Reichenbachia 3:313. Synonymy
Diagnosis.- This species is distinguished from other North and Central American representatives of the genus by the tuberculate declivital interstriae 1, with interstriae 2 unarmed.

Female.- Length 1.9-2.4 mm, 3.0 times as long as wide; color dark brown.

Frons and pronotum essentially as in intersetosus (Blandford) except pronotal asperities slightly larger, punctures on pronotal disc slightly smaller.

Elytral outline and disc as in aspericauda (Eggers) except posterior outline straight on median third, not emarginate, and interstrial punctures on disc almost obsolete. Declivity essentially convex, very shallowly bisulcate; strial punctures about as on disc; interstriae 1 and 3 feebly elevated, each armed by a row of about five to seven pointed tubercles, those on lower fifth usually reduced or obsolete on 1; 2 slightly narrower than 1 or 3 , weakly impressed, unarmed, impunctate, one or two minute granules near base, 4-7 each with a few smaller pointed tubercles; posterolateral margin rounded. Vestiture as in aspericauda except setae near declivity slightly longer, those on declivital interstriae 2 obsolete.

Male.-Length $1.6-1.8 \mathrm{~mm}$; similar to female except smaller, all characters poorly
formed, pronotal asperities and declivital granules much smaller.

Distribution.- British Columbia and Maine to Baja California, Hidalgo, and Florida; Europe, Asia, Australia, Hawaii, Argentina, Brazil, Chile.

CANADA: British Columbia, Ontario. USA: Alabama, Arizona, Arkansas, California, Connecticut, Delaware, Florida, Georgia, Illinois, Indiana, Iowa, Kansas, Kentucky, Louisiana, Maine, Maryland, Massachusetts, Michigan, Mississippi, Missouri, New Hampshire, New Jersey, New York, North Carolina, Ohio, Oregon, Pennsylvania, South Carolina, ennessee, Texas, Utah, Virginia, Washington. MEXICO: Baja California, Hidalgo.

Hosts.- Numerous trees and shrubs.
Biology.- This species attacks recently cut, injured, and dying material from 5-50 cm in diameter. The attacking female constructs a radial entrance tunnel through the bark and about $1-7 \mathrm{~cm}$ into the wood. In the innermost section, she enlarges the upper and lower walls parallel to the grain of the wood. She then deposits eggs in this section of the tunnel. The larvae apparently feed on a combination of ambrosial fungus and wood obtained from continuing the tabular excavation of their mother. The mature tunnel is of a tabular cave type, with the broad axis parallel to the grain of the wood. At times the entire cavity is a mass of larvae. One to two months are required to complete a generation under favorable conditions. Blackman (1922) recorded a sex ratio of 1 male to 7 fe males, but field observations suggest a more normal ratio is 1 to 15 . This species is capable of causing rather severe economic damage.

## 10. Xyleborinus aspericauda (Eggers)

Xyleborus aspericauda Eggers, 1941, Arb. Morph. Taxon. Ent. Berlin-Dahlem 8:106 (Holotype, female; Guadeloupe 1sland; Fleutiaux Coll.)
Diagnosis.- This species is distinguished from saxeseni (Ratzeburg) by the absence of an elevation and of denticles on declivital interstriae 1 , and by the rather strongly elevated ventrolateral area of the declivity, which is armed by 15-20 denticles.

Female.- Length $1.6-1.9 \mathrm{~mm}, 3.0$ times as long as wide; color dark brown to black.

Frons as in intersetosus.
Pronotum 1.2 times as long as wide; sides straight and parallel on almost basal twothirds, rather narrowly rounded in front;
anterior margin feebly serrate; summit slightly more than one-third pronotum length from anterior margin; anterior slope rather finely asperate; posterior areas reticulate, punctures fine, moderately abundant. Vestiture fine, short, sparse in discal area, longer and rather coarse on asperate area.

Elytra 1.7 times as long as wide, 1.4 times as long as pronotum; sides straight and parallel on basal two-thirds, then slightly tapered, shallowly, broadly emarginate on median third behind; scutellum as described for genus; disc confined to basal 60 percent; striae not impressed, punctures small, spaced within row by diameter of a puncture; interstriae almost smooth, shining, about two and one-half times as wide as striae, punctures fine, two-thirds as large as those of striae, those near declivity finely granulate. Declivity rather steep, somewhat flattened on basal half, rather broadly sulcate below; striae 1 weakly impressed, punctures slightly larger than on disc; interstriae 1 and 2 almost flat, unarmed, 2 narrowed, then obsolete on lower third; lateral area on less than lower third elevated, rounded, armed by about 15
pointed tubercles, one or two of those on summit of elevation on interstriae 3 distinctly larger. Vestiture of minute, almost obsolete strial hair, and rows of longer, erect, coarse, interstrial hair, each hair about as long as distance between rows, similarly spaced within a row.

Distribution.-S Florida and Costa Rica to Colombia and Venezuela.

USA: Florida: Biscayne Bay. COSTA RICA: Finca Gromaco on Río Coto Brus, Puntarenas, 14-VII-63, 500 m, No. 87, tree branch, S. L. Wood; Rincón de Osa, Puntarenas, II-VIII-66, 30 m , Nos. 55, 65. liana, S. L. Wood; San Isidro del General, San José, 5-XII-63, I000 m, No. 284, Miconia pubescens, S. L. Wood; Turrialba, Cartago, 1970, R. I. Gara; Guápiles, Limón, 22-VII-66, I 00 m , No. 119, Terminalia, S. L. Wood; Finca La Lola, Limón, 4-III-63, Theobroma cacao, J. L. Saunders. PANAMA: 13 km S El Hato del Volcán, Chiriquí, 7-I-64, 1000 m . No. 371 , tree sapling, S. L. Wood. OTHER COUNTRIES: Colombia, Venezuela, Guadeloupe.

Hosts. - Terminalia sp., Theobroma cacao, etc.

Biology.- Specimens were taken from material $5-50 \mathrm{~cm}$ in diameter.

Notes.- The above treatment was based on 39 specimens, 2 of which were compared to Schedl's series of this species. The type was not located.

Tribe CRYPHALINI

Cryphaloideae Lindemann, 1876, Bull. Soc. Imp. Nat. Moscou 51: 165 (Type-genus: Cryphalus Erichson, 1836) Ernoporinae Nüsslin, 1911, Zeitschr. wissensch. Insektenbiol. 7:375 (Type-genus: Ernoporus Thomson, 1859) Trypophloeinae Nüsslin, 1911, Zeitschr. wissensch. Insektenbiol. 7:375 (Type-genus: Trypophloeus Fairmaire, 1868) Eidophelinae Murayama, 1954, Bull. Fac. Agric. Yamaguti Univ. 5:200 (Type-genus: Eidophelus Eichhoff, 1875)

Anatomical features. - The frons is usually convex and is rarely dimorphic, the eye is usually entire (shallowly emarginate in Stegomerus, Cryphalus, Hypocryphalus, Hypothenemus, Cryptocarenus), the antennal funicle is $3-5$-segmented, the club is flattened, when present, the sutures on the posterior face are strongly displaced toward the apex, the anterior area of the pronotum is declivous and asperate, its lateral margins may be rounded or marked by an acutely raised line, the procoxae are contiguous, the tibiae are rather strongly flattened and usually armed by more than four socketed denticles, the costal margin of the elytra ascends from the base of the declivity to its apex, and the males are dwarfed and deformed in Trischidias, Hypothenemus, and Cryptocarenus.

Biological features.- All are monogamous and they are either phloeophagous or pith borers. Parental galleries are usually of a modified cave type. Eggs are deposited in the parental gallery. Larvae may make individual mines or extend the parental tunnel. Males of Trischidias, Hypothenemus, and Cryptocarenus are flightless and do not join the female in the construction of parental galleries; these genera practice consanguineous polygyny and arrhenotokic parthenogenesis; the males are presumed to be haploid.

Taxonomy.- The generic classification of this tribe is in chaos. Stegomerus, Trischidias, and Cryptocarenus are restricted to tropical America. Trypophloeus, Ernoporicus, Procryphalus, and North American Cryphalus are of Eurasian origin and reached North America rather recently. Scolytogenes and Hypothenemus are circumtropical, their origins not known. This is one of the largest and most difficult tribes to classify in the family.

## Genus TR YPOPHLOEUS Fairmaire

Trypophloeus Fairmaire, 1868, in Jacquelin du Val and Fairmaire, Genera des Coleopteres d'Europe 4:105 (Type-species: Bostrichus binodulus Ratzeburg, monobasic).
Glyptoderus Eichhoff, 1878, Mém. Soc. Roy. Sci. Liége, ser. 2, 8:34, 44, 137 (Type-species: Bostrichus binodulus Ratzeburg, subsequent designation by Hopkins, 1914, Proc. U.S. Nat. Mus. 48:122); Bedel, 1888, Ann. Soc. Ent. France, hors ser., 6:397. Synonymy
Diagnosis.- This genus is distinguished from Procryphalus Hopkins by the 5 -segmented antennal funicle, by the smaller, slender, apically pointed, aseptate antennal club, and by the absence of scalelike setae on the basal half of the pronotum.

Description.- Length 1.5-2.1 mm, 2.3-2.5 times as long as wide; color dark brown to black; sexes similar; frons convex, conservatively sculptured. Eye entire, finely granulate. Antennal funicle 5 -segmented, club elongate, apically pointed. Pronotum with summit at middle; anterior area asperate, punctured posteriorly; anterior margin armed; lateral margins rounded, not marked by a raised line. Elytral striae indicated or not, interstriae and declivity conservatively sculptured; costal margin ascending very slightly toward apex. Vestiture of abundant, short ground cover of scales and/or hair and interstrial rows of erect setae. Prothoracic tibiae broadened distally, armed on distal third of lateral margin by about eight teeth, hind tibiae somewhat similar, armed by about six teeth.

Distribution. - Northern areas of North America, Europe, and Asia; four species occur in North America and about a dozen in Europe and Asia.

Biology.- The species of this genus are monogamous and phloeophagous. They con-
struct cave-type tunnels in the bark immediately below the outer surface in unthrifty, living trees. The cavity is stained black,
suggesting the presence of fungal growth that may play a significant role in their nutrition. Larval mines are short and winding.

## Key to the Species of Trypophloeus <br> (Modified from Wood 1954)

1. Strial punctures impressed, at least on basal third of disc, diameters of largest punctures about equal in width to adjacent interstriae; vestiture hairlike on basal half of disc, either hair- or scalelike on declivity; declivital interstrial bristles distinctly longer than half of distance between rows

- Strial punctures obscure, their diameters much less than width of an adjacent interstriae; vestiture scalelike on at least posterior three-fourths of elytra; declivital interstrial bristles shorter, their length equal to less than half distance between rows
2(1). Strial punctures on more than basal half of disc coarse, deep; punctures on posterolateral areas of pronotum rather large, deep, close; scalelike setae confined to elytral declivity; Alaska and Utah to Nova Scotia; Alnus, Salix; 1.6-2.0 mm 1. striatulus (Mannerheim)
- Strial punctures greatly reduced except on basal fourth of disc; punctures on posterolateral areas of pronotum rather small, shallow, not as close; scalelike setae covering posterior half of elytra; Washington to California; Alnus, Salix; $1.5-1.7 \mathrm{~mm}$

2. salicis Hopkins

3(1). Apex of interstriae 4 smooth or with minute, rounded granules; elytral scales abundant, broad, their apices rounded; front convex; E Nevada and Arizona to Saskatchewan and New Brunswick; Populus; 1.7-2.1 mm
3. populi Hopkins

- Apex of interstriae 4 armed by a row of 1-5 small, slender, pointed teeth, each at least twice as long as its basal width; elytral scales abundant, their apices acuminate; frons usually subconcavely impressed; British Colombia to California; Populus; 1.5-1.9 mm

4. thatcheri Wood
5. Trypophloeus striatulus (Mannerheim)
Fig. 194

Cryphalus striatulus Mannerheim, 1853, Bull. Soc. Imp. Nat. Moscou 26:235 (Holotype, sex?; Kenai Peninsula, Alaska; not in Helsinki Mus., presumably lost)
Trypophloens striatulus: Wood, 1969, Great Basin Nat. 29:115
Trypophloeus nitidus Swaine, 1912, Canadian Ent. 44:349 (Lectotype, sex?; Weymouth, Nova Scotia: Canadian Nat. Coll., 9276, designated by Bright. 1967, Canadian Ent. 99:679); Wood, 1969, Great Basin Nat. 29:115. Synonymy
Trypophloeus punctipemnis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:37 (Holotype, female; Alta, Utah; U.S. Nat. Mus., 7399); Wood, 1954, Univ. Kansas Sci. Bull. 36:990. Synonymy
Diagnosis.- The coarse strial punctures extending at least two-thirds of the distance from the elytral base to the declivity, and the absence of scalelike pubescence, except to a limited extent on the declivity, distinguish this species from other North American representatives of this genus.

Female.- Length $1.6-2.0 \mathrm{~mm}, 2.45$ times as long as wide, body color black.

Frons convex, with a variable Y-shaped impression beginning above upper level of eyes, branching above epistoma and continuing to margins of antennal insertions; surface coarsely reticulate above upper level of eyes, coarsely, shallowly, closely punctured below; pubescence consisting of inconspicuous, fine, sparse hair of medium length. Eye elongateovate, wider above, about 2.2 times as long as wide, finely granulate; entire or with two or three facets missing, suggesting an emargination. Antennal club longer than scape, about 1.69 times as long as wide, with three straight sutures indicated by rows of setae.

Pronotum 0.94 times as long as wide; anterior margin slightly produced, with four to eight contiguous or subcontiguous teeth, lateral ones reduced in size; summit slightly behind middle; asperate in front of summit, asperities rather large, abundant; posterior and
lateral areas shining, punctures rather close, coarse, rather deep; pubescence consisting of rather short, fine, erect hair, slightly longer in asperate area.

Elytra shining; striae not impressed, punctures rather coarse and deeply impressed on anterior two-thirds of disc, usually becoming smaller and shallow near declivity; interstriae (anteriorly) about as wide as striae, becoming subcrenulate at base, punctures fine, shallow, confused, rather abundant, subgranulate anteriorly. Declivity rather steep, convex; striae weakly impressed, punctures reduced; interstriae each with a uniseriate row of small, rather widely spaced granules. Elytral vestiture on disc and sides consisting of rather abundant, short, hairlike strial and interstrial setae and uniseriate rows of longer hairlike bristles; on declivity both short and long setae become stout and more nearly scalelike.

Male.- Similar to the female.
Distribution.-Alaska and Utah to Newfoundland and Nova Scotia.

ALASKA: 33 km ( 21 miles) E Cantwell, 30 -vili-67, Hopk. US 48895, M. M. Furniss: Kongakut River, Brooke Range ( $69^{\circ} 15^{\prime} \mathrm{N} .141^{\circ} 45^{\prime} \mathrm{W}$ ), 26-VlII-74, M. M. Furniss. CANADA: Newfoundland: Fort Blandford, IV-25, Alnus. Nova Scotia: Weymouth, No. 172, A. incana. Quebec: Laniel, 27-VIII-35, Salix, H. S. Fleming. Yukon Territory: Mile 105 Dawson Road, 28-VI-60, Salix; North Fork Pass, Ogilvie Mts., 19-V1-62, 4300 ft ., R. E. Leech. USA: Colorado: Gould, 12-VI-28, Salix, S. L. Wood. Idaho: Coeur d'Alene, 8-XII-15, Almus, J. C. Evenden, and 5-IV-29, H. J. Rust; Poison Creek, 20 miles SW Grandview, 31-VII-67, M. M. Furniss. Minnesota: Ely, Lake Co., 10-IX-36, A. crispa, H. R. Dodge. Utah: Alta, 30-VI, E. A. Schwarz; Logan Canyon, 17-VII-46, 7000 ft , S. scouleriana, S. L. Wood.

Hosts.-Alnus crispa, A. rugosa, Salix scouleriana, S. sp.

Biology.- As described for the genus. Unthrifty, mature limbs of living trees are selected for attack. The attack is progressive and may continue for several generations on the same limb, ultimately resulting in its death.

Notes. - The above treatment was based on the lectotype of nitidus, the holotype of punctipennis, and on 115 other specimens.

There are no specimens in the Mannerheim Collection under this name, nor are there American specimens of this or a related genus among the undetermined material. In view of the fact that the only Cryphalini in the impoverished northern fauna with distributions reaching to or near Kenai are nitidus
and Cryphalus ruficollis Hopkins, and, considering Mannerheim's knowledge of the European fauna and his comparison of striatulus to Trypophloeus granulatus (Ratzeburg) rather than to Cryphalus asperatus (Gyllenhal), it is reasonably certain that striatulus and nitidus are the same species. The type specimen of striatulus was taken at Lake Skeljamma, Kenai Peninsula, Alaska, in midJune, in flight, by D. F. Frankenhauser. My series from Cantwell, Alaska, 200 miles north of the type locality, is entirely typical of the species.

## 2. Trypophloeus salicis Hopkins

Fig. 194
Trypophloeus salicis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:36 (Holotype, female; Del Monte, California; U.S. Nat. Mus., 7395)
Trypophloeus concentralis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:36 (Holotype, male; Easton, Washington; U.S. Nat. Mus., 7398); Wood, 1954, Univ. Kansas Sci. Bull. 36:991. Synonymy
Diagnosis.- This species is distinguished from striatulus (Mannerheim) by the scalelike pubescence of the elytra covering the posterior one-half, including part of the disc, by having the strial punctures coarse and impressed on less than the anterior one-third of the elytra, and by having the punctures on the posterolateral areas of the pronotum smaller and shallow.

Female.- Length $1.5-1.7 \mathrm{~mm}, 2.5$ times as long as wide, body color dark brown.

Frons flattened on a rather broad area, subconcave in some Washington specimens; rather weakly impressed above epistoma, with a short median prominence reaching epistoma; surface coarsely, closely, shallowly punctured at sides and above, indistinctly punctured toward center; pubescence consisting of inconspicuous, fine, sparse hair of medium length. Eye elongate-ovate, wider above, about 2.2 times as long as wide; finely granulate; entire or with two or three facets missing, suggesting an emargination. Antennal club longer than scape, about 1.70 times as long as wide, with three straight sutures indicated by rows of setae.

Pronotum 0.92 times as long as wide; anterior margin very slightly produced, with six subcontiguous teeth (rarely an additional pair of granules), lateral pair reduced in size; summit slightly behind middle; asperate in front
of summit, asperities rather large, abundant; posterior and lateral areas usually reticulate, and with small, rather close, shallow punctures; pubescence consisting of rather short, fine, erect hair, slightly longer in asperate area.

Elytra shining; striae not impressed, punctures rather coarse and quite deep on basal fourth of disc, less than half as large on posterior three-fourths; interstriae on basal fourth only slightly wider than striae, much wider posteriorly, usually subcrenulate toward base, punctures about as large as those of striae on posterior three-fourths of disc, confused; a uniseriate row of widely spaced, fine granules on each interstriae, each granule bearing an interstrial bristle. Declivity moderately steep, with a broad, shallow impression between interstriae 1 and 4; striae obscure; interstriae each with a row of fine granules, posterior extremity of 4 slightly elevated and bearing one to four larger, sharply pointed, toothlike granules. Elytral vestiture consisting of numerous, short, semirecumbent strial and interstrial setae and uniseriate rows of longer, erect bristles; both types of setae hairlike on anterior half of elytra, scalelike on posterior half, particularly on declivity.

Male.- Similar to female.
Distribution. - Washington to California.
USA: California: Belmont; Del Monte, 4-1X-02, Hopk. US 1092. Salix, A. D. Hopkins; Cotati. 17-V-49, C. Calkins. Oregon: Portland, 12-V11-40, Salix, J. Schuh. Washington: Easton, A. Koebele; Ft. Flagler, 19-X11-41, Alnus, T. O. Thatcher.
Hosts.- Alnus sp., Salix sp.
Biology.- As in striatulus.
Notes.- The above treatment was based on the holotypes of salicis and concentralis and on seven other specimens.

## 3. Trypophloeus populi Hopkins

Figs. 191, 193, 194
Trypophloeus populi Hopkins, 1915, U.S. Dept. Agric. Rept. 99:37 (Holotype, female: Williams, Arizona; U.S. Nat. Mus., 7397)
Diagnosis.- This species differs from the very closely allied thatcheri Wood by the absence of small slender teeth at the end of interstriae 4 , by the wider, apically rounded elytral scales, and by the more evenly convex frons.

Female.- Length $1.7-2.1 \mathrm{~mm}, 2.3$ times as long as wide, body color black.

Frons variable, flattened or weakly convex, rather weakly impressed above epistoma, occasionally with a more or less distinct median impression or elevation; surface coarsely reticulate above eyes, closely, coarsely, rather deeply punctured below; pubescence consisting of inconspicuous, fine, sparse hair of medium length. Eye elongate-ovate, wider above, twice as long as wide; finely granulate; entire or with two or three facets missing, suggesting an emargination. Antennal club longer than scape, about 1.87 times as long as wide, with three straight sutures indicated by rows of setae.

Pronotum 0.88 times as long as wide; anterior margin slightly produced, with four rather large, subcontiguous teeth, median pair larger, often with two additional smaller lateral granules; summit slightly behind middle; asperate in front of summit, asperities rather large, abundant; posterior and lateral areas shining, punctures rather close, coarse, quite deep; pubescence consisting of rather short, fine, semierect hair, some of these setae stout and almost scalelike on basal portion.

Elytra shining; striae not impressed, punctures reduced in size, shallow, usually obscure; interstriae with numerous, fine, confused, shallow punctures about equal in size to those of striae; usually bearing a uniseriate row of widely spaced, fine granules, each granule bearing an interstrial bristle. Declivity rather steep, convex except for a slight impression between interstriae 1 and 4; striae usually obscure; interstriae each with a row of fine granules, posterior extremity of 4 very slightly elevated, granules scarcely larger than on other interstriae. Elytral vestiture consisting of numerous short, semirecumbent, interstrial scalelike setae; and uniseriate rows of rather widely spaced, scalelike bristles, each bristle about two times as long as shorter scales, both types of setae covering elytra from base to posterior margin.

Male.- Similar to female.
Distribution.-E Nevada and N Arizona to Saskatchewan and New Brunswick.

CANADA: Manitoba: Aweme. New Brunswick: Fredericton, IX-52, aspen, G. W. Barter. Saskatchewan: Indian Head, 9-V11-43, 29-V1-42, aspen. USA: Arizona: Williams, Populus tremuloides, H. S. Barber, E. A. Schwarz. Colorado: Bellvue, 10-X-51, P. acuminata, T.
O. Thatcher. Idaho: South Mountain, 3-IX-58, P. tremuloides, M. M. Furniss. Nevada: Baker, 5-VI-39, P. trichocarpa, T. O. Thatcher. Utah: Logan, 5-VIII-52, P. angustifolia, S. L. Wood; Logan Dry Canvon, 29-VII-46, P. tremuloides, S. L. Wood; Provo Canyon, 20-IX-73, P. tremuloides, S. L. Wood.

Hosts.- Populus acuminata, P. angustifolia, P. tremuloides, P. trichocarpa.

Biology.- The smooth green bark of limbs or bole of standing, dying trees is selected for attack; less commonly broken limbs are utilized. The parental galleries are immediately below the outer surface of the bark; larval mines penetrate more deeply into the thick bark. The attack of this species precedes that of Procryphalus mucronatus (LeConte) and usually subsides before the tree appears to be unthrifty (Petty 1977). The attack appears to be primary, and there are unproven indications of disease transmission by this species.

Notes.- The above treatment was based on the holotype and on 189 other specimens.

## 4. Trypophloeus thatcheri (Wood), n. comb.

Cryphalus thatcheri Wood, 1954, Univ. Kansas Sci. Bull. $36(2): 994$ (Holotype, female; 2 miles NW Blue Lake, Lassen Co., California; Snow Ent. Mus., Univ. Kansas)
Diagnosis.- This species is distinguished from populi Hopkins by the presence of a row of one to five small slender teeth at the posterior end of interstriae 4, each tooth at least twice as long as its basal width; by the short, abundant acuminate elytral scales, and by the usually subconcavely impressed frons.

Female.- Length $1.5-1.9 \mathrm{~mm}, 2.26$ times as long as wide, body color black.

Head and pronotum as in populi.
Elytra shining; striae not impressed, punctures reduced in size, shallow, usually obscure; interstriae with numerous, fine, confused, shallow punctures about equal in size to those of striae, each usually bearing a single uniseriate row of widely spaced, fine granules, each granule bearing an interstrial bristle. Declivity rather steep; convex except for a broad, indistinct impression between interstriae 1 and 4; striae usually obscure; interstriae each with a row of small granules; posterior extremity of interstriae 4 slightly elevated and bearing a row of one to five small, slender, sharply pointed, toothlike
granules, each tooth at least twice as long as its basal width. Elytral vestiture consisting of numerous short, semirecumbent, scalelike, interstrial setae, each scale more or less acuminate, and uniseriate rows of rather widely spaced, scalelike bristles, each with an interstrial granule at its base, each bristle about two to three times as long as shorter scales, both types becoming more nearly hairlike near elytral base.

Male.- Similar to female; average size of male may be slightly smaller. Because of difficulty of determining sex and small number of specimens at hand, this observation not fully verified.

Distribution.- British Columbia to California.

CANADA: British Columbia: Douglas Lake, 28-VIII6I, Populus trichocarpa, J. Grant; Squilax, 8-I-62, P. trichocarpa, J. Grant. USA: California: 2 miles NW Blue Lake, Lassen Co., 19-VII-47, Populus tremuloides, T. O. Thatcher; Warner Mts., Modoc Co., 10-VII-I0; Sonora Pass, 4-VIII, J. N. Knull; Pasadena.

Host.-Populus tremuloides, $\quad P$. trichocarpa.

Biology.- As in populi.
Notes.- The above treatment was based on the type series of 61 specimens and on 14 other specimens.

## Genus StEGOMERUS Wood

Stegomerus Wood, 1967, Great Basin Nat. 27:129 (Typespecies: Stegomerus vulgaris Wood, original designation)
Diagnosis.- This genus is distinguished from the allied Ernoporus Thomson by the 5segmented antennal funicle, and by the emarginate eye.

Description.- Length 0.9-2.1 mm, 2.5-2.6 times as long as wide; sexes similar, frons slightly impressed in males of some species; frons simple. Eye elongate, finely granulate, broadly emarginate. Antennal scape short; funicle 5 -segmented; club large, strongly flattened, with three aseptate, procurved sutures. Pronotum with summit conspicuous, anterior slope asperate, anterior margin armed, basal and lateral margins rounded not marked by a raised line. Elytra elongate, costal margins feebly elevated toward apex. Tibiae gradually widened from base, obliquely narrowed toward apex; lateral margins armed by several small teeth; tarsal segments narrow, laterally compressed.

Distribution.- Mexico to Venezuela; six species, one of which occurs in South America.

Biology.- These monogamous beetles breed in recently cut and dying vines and lianas larger than 1 cm in diameter. The
parental tunnels are constructed in the cambium region in an H -shaped pattern, with longitudinal egg galleries; the entrance tunnel is on the transverse connecting portion of the system. Larval mines are longitudinal.

## Key to the Species of Stegomerus <br> (Modified from Wood 1967)

1. Interstrial scales and hair in uniseriate rows on disc and declivity; striae clearly evident; Nayarit to Costa Rica; Canavalia, etc.; $0.9-1.2 \mathrm{~mm}$....... 1. pygmaets Wood

- Elytral vestiture and punctures abundant, confused on declivity; usually larger than 1.4 mm 2
2(1). Setae on basal half of elytral interstriae 9 and 10 consisting of fine, long hair; suture 2 on antennal club much more strongly procurved than suture 1 ; scales on elytral disc almost in uniseriate rows3
- Setae on basal half of elytral interstriae 9 and 10 primarily scalelike, short; sutures 1 and 2 on antennal club equally, weakly procurved: scales on elytral disc abundant, confused4

3(2). Smaller, 1.3-1.6 mm; scales on declivital interstriae 2 and 3 mostly uniseriate; punctures of striae and interstriae somewhat smaller, essentially in rows; Panama; Canacalia; 1.3-1.6 mm 2. chriquensis Wood

- Larger, $1.8-2.1 \mathrm{~mm}$; scales on all declivital interstriae strongly confused; punctures of striae and interstriae coarser, completely confused; Costa Rica; Muelenbeckia; 1.8-2.1 mm

3. montanus Wood

4(2). Scales on at least some of discal interstriae between 3 and 9 in uniseriate rows; declivital scales broad, usually less than twice as long as wide, apex of each scale truncate; Michoacán to Puebla; Seriania; 1.4-1.7 mm $\qquad$ 4. mexicanus Wood

- Scales on discal interstriae multiple, confused; declivital scales more than twice as long as wide, apex of each scale rounded; Guatemala to Costa Rica; Seriania; 1.7-2.0 mm 5. vulgaris Wood

## 1. Stegomerus pygmaeus Wood

Stegomerus pygmaeus Wood, 1967, Great Basin Nat. 27:130 (Holotype, male; Los Corchos, Nayarit, Mexico; Wood Coll.)
Diagnosis.-As indicated in the key, this species is distinguished from others in the genus by its small size and by the uniseriate strial and interstrial punctures, with the elytral scales and hair in rows.

Male.- Length 0.9-1.2 mm, 2.5 times as long as wide; color dark brown, summit of pronotum and elytra somewhat lighter.

Frons narrow, convex above, flat below, epistomal margin and its obtuse, median lobe
slightly elevated; surface reticulate above, subreticulate below, and finely, sparsely punctured; vestiture on flattened area moderately abundant, consisting of fine, rather long hair. Eye elongate, about three times as long as wide; shallowly, broadly emarginate, rather finely faceted. Antennal scape shorter than the 5 -segmented funicle; club marked by three equally, slightly procurved sutures.

Pronotum 1.0 times as long as wide; widest one-third of length from base, sides weakly arcuate, broadly rounded in front; armature on anterior margin poorly developed; summit at middle, prominent; anterior area rather
coarsely asperate; posterior and lateral areas almost smooth and shining, with small, rounded, isolated granules; vestiture consisting of hairlike setae over entire surface, with erect scales intermixed on posterior half.

Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; sides straight and parallel on more than posterior two-thirds, rather broadly rounded behind; striae 1 feebly, others not impressed, punctures small, shallow; interstriae slightly wider than striae, punctures fine, uniseriate. Declivity moderately steep, convex; similar to disc except strial and interstrial punctures smaller and somewhat obscure. Vestiture consisting of uniseriate rows of short, semirecumbent strial hair and erect interstrial scales, each scale about three times as long as wide.

Female.-Similar to male except lower half of frons more nearly convex.

Distribution.- Nayarit to Costa Rica.
MEXICO: Jalisco: La Huerta, 1-VII-65, 500 m , No. 172, Canatalia. Nayarit: Los Corchos, $10-\mathrm{VII}-65,20 \mathrm{~m}$, No. 210, Canavalia villosa. HONDURAS: Zamorano, Morazán, 18-1V-64, 700 m , No. 560 from Dioclea megacarpa. No. 537 from Canacalia tillosa; La Lima, 5-V-65, No. 581, Cestrum scundens. COSTA RICA: San José, San José, 22-X-63, 1600 m, No. 257. Canaralia tillosa. All were taken by me.

Hosts.- Canavalia villosa, Cestrum scandens, and Dioclea megacarpa.

Biology.- Presumably as described for the genus; the stem structure of the host and the small size of the beetle made observation difficult.

Notes.- The above treatment was based on the type series of 49 specimens and on 61 other specimens.

## 2. Stegomerus chiriquensis Wood

Stegomerus chiriquensis Wood, 1967, Great Basin Nat. 27:131 (Holotype, male; Cerro Punta, Chiriquí, Panama; Wood Coll.)
Diagnosis.- As indicated in the key, this species is allied to montanus, but it is distinguished by the smaller size and by the different arrangement of elytral punctures and scales.

Male.- Length 1.3-1.6 mm, 2.6 times as long as wide; color light brown, a few specimens much darker.

Frons convex above, rather strongly, transversely impressed near middle, flattened below; a median epistomal lobe present; surface
reticulate, with moderately abundant, fine, obscure punctures; vestiture fine, rather sparse. Eye elongate, about three times as long as wide; broadly, rather deeply emarginate; rather coarsely faceted. Antennal scape shorter than 5 -segmented funicle; club large, longer than combined length of scape and funicle, three procurved sutures subangulate at middle, suture 1 partly septate.

Pronotum as in pygmaeus, except anterior margin armed by a series of about six small teeth.

Elytra 1.6 times as long as wide, 1.7 times as long as pronotum; punctures of striae and interstriae very close, moderately large and deep, in obscure rows. Declivity rather steep, convex; strial punctures slightly smaller and interstrial punctures much smaller on disc, shallow, in rows. Vestiture consisting of uniseriate rows of short, fine, recumbent strial hair and longer, erect interstrial scales, each scale four or five times as long as wide; sutural margin on declivity with an additional row of shorter scales; an occasional scale on declivity not in rows.

Female.-Similar to male except transverse frontal impression obscure or absent.

Distribution.- Panama.
PANAMA: Cerro Punta, Chiriquí, 11-I-64, No. 495, Canaralia cillosa, S. L. Wood.

Brology.- Essentially as described for the genus.

Notes. - The above treatment was based on the type series of 51 specimens.

## 3. Stegomerus montanus Wood

Stegomerus montanus Wood, 1967, Great Basin Nat. 27:132 (Holotype, male; Volcán lrazu, Cartago, Costa Rica; Wood Coll.)
Diagnosis.- As indicated in the above key, this species is distinguished from the closely allied chiriquensis Wood by the larger size and by the different arrangement of elytral setae.

Male.- Length $1.8-2.1 \mathrm{~mm}, 2.6$ times as long as wide; color dull black or grayish black, with elytra and summit of pronotum having a reddish cast.

Frons, eyes, and antenna as in chiriquensis.
Pronotum 1.0 times as long as wide; widest on basal fourth, sides very feebly arcuate and converging slightly toward rather narrowly rounded anterior margin; summit at middle,
impressed behind; surface and vestiture about as in chiriquensis.

Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; disc densely, deeply, rather finely punctured, punctures separated by distances less than half width of a puncture, confused. Declivity rather steep, convex; striae and interstriae not distinguishable, punctures obscure. Vestiture consisting of rows of minute strial hair between confused rows of slender scales; setae on interstriae 9 and 10 from base to declivity consisting of fine hair only.

Female.- Similar to male except frons flattened, not transversely impressed.

Distribution.- Costa Rica.
COSTA RICA: Volcán Irazu, Cartago, 28-VI-63, 2800 m, No. 5, Muelenbeckia tamnifolia, S. L. Wood; Villa Mills on Cerro de la Muerte, Cartago, I-V1II-66, 3000 m, M. tamnifolia, S. L. Wood.

Host.- Muelenbeckia tamnifolia.
Biology. - The above description of habits for the genus was based largely on this species. Larvae usually mine the phloem tissues; young adults commonly tunnel into deeper tissues.

Notes.- The above treatment was based on the type series of 31 specimens.

## 4. Stegomerus mexicanus Wood

Stegomerus mexicanus Wood, 1967, Great Basin Nat. 27:133 (Holotype, male: 21 km W' Morelia, Michoacán, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from vulgaris Wood by the shape and arrangement of the elytral scales, as indicated in the above key.

Male.- Length $1.4-1.7 \mathrm{~mm}, 2.5$ times as long as wide; color rather light brown, some specimens dull black, with light vestiture.

Frons, eye, antennal scape, and funicle as in chiriquensis; antennal club larger, 1.3 times as long as wide, with three equally, weakly procurved sutures indicated.

Pronotum as in chiriquensis, but narrowly rounded in front; anterior margin armed by four large teeth.

Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; sides straight and parallel on basal three-fourths, broadly rounded behind; disc with shallow, confused, close, indefinite punctures. Declivity rather steep, convex; surface as on dise except punctures
evidently very feebly granulate. Vestiture consisting of uniseriate rows of fine strial hair and confused rows of erect interstrial scales, at least some of rows between interstriae 4 and 9 uniseriate; each scale about three to four times as long as wide.

Female. - Similar to male except frons not as strongly flattened.

Distribution.- Michoacán to Puebla.
Mexico: Michoacán: 21 km W Morelia, 15-VI-65, 2300 m , No. 59, Seriania, S. L. Wood. Puebla: 11 km S Atlixco, 13-111-53, No. 102, S. L. Wood.

Host.-Serjania sp.
Biology.- Essentially as described for the genus. It breeds in stems less than 1 cm in diameter.

Notes.- The above treatment was based on the type series of 53 specimens and on one other specimen.

## 5. Stegomerus culgaris Wood

Stegomerus tulgaris Wood, 1967, Great Basin Nat. 27:134 (Holotype, male: Volcán Zunil, Quezaltenango, Guatemala; Wood Coll.)
Diagnosis. - In the above key this species is placed near mexicanus Wood; it is distinguished by the shape and arrangement of the elytral scales.

Male.- Length $1.7-2.0 \mathrm{~mm}, 2.6$ times as long as wide; color light brown, some specimens with areas almost dull black.

Frons weakly convex, slightly impressed just above epistoma; premandibular epistomal process evident, projecting very slightly as a median epistomal lobe; surface coarsely reticulate, with moderately large, indefinite, isolated granules in central area, reduced in marginal areas. Eye three times as long as wide; coarsely faceted; about one-fourth divided by a broad emargination. Antennal scape and 5 -segmented funicle short, subequal in length, their combined length distinctly less than length of club; club subcircular, 1.1 times as long as wide, divided into four subequal segments by three broadly procurved sutures, suture 1 partly septate at both ends.

Pronotum 1.0 times as long as wide; widest one-third of length from base; basal angles rounded, sides rather strongly, arcuately converging toward narrowly rounded anterior margin; anterior margin armed by about six teeth; oval area on anterior slope coarsely
asperate; summit elevated, near middle; posterior areas subreticulate-granulate, with moderately large, rather close, rounded granules; vestiture hairlike, except mixed with scales on basal fourth.

Elytra 1.7 times as long as wide, 1.8 times as long as pronotum; scutellum rather large, triangular, flat; sides straight and parallel on basal three-fourths, somewhat narrowly rounded behind; disc closely, obscurely punctured, punctures shallow, confused. Declivity rather steep, convex; striae 1 and 2 obscurely indicated (largely by color), otherwise similar to disc. Vestiture consisting of small, obscure, uniseriate rows of strial hair and abundant, confused, erect interstrial scales, each scale about four times as long as wide.

Female.-Similar to male except frons very slightly, more strongly convex.

Distribution.- Guatemala to Costa Rica.
GUATEMALA: Volcán Zunil, Quezaltenango, 27-V$64,1000 \mathrm{~m}$, No. 630, liana; Palin, Esquintla, 19-V-64, 350 m, No.682, Serjania. HONDURAS: San Lucas, Paraiso, 22-1V-64, 800 m , No. 523A. S. mexicana; Zamorano, Morazán, 18-IV-64, 700 m , No. 507, S. triquetra. COSTA RICA: San José, San José, 22-X-63, 1300 m , No. 168, evidently Seriania. All were taken by me.

Hosts.- Serjania mexicana, S. triquetra, S. sp .

Biology.- As described for the genus.
Notes. - The above treatment was based on the type series of 132 specimens.

## Genus ERNOPORICUS Berger

Ernoporicus Berger, 1917, Rev. Russe Ent. 16:242 (Typespecies: Emoporicus spessictzevi Berger, monobasic)
Empocerus Balachowsky, 1949, Faune de France 50:211 (Type-species: Ernoporus caucasicus Lindemann, designated by Wood, 1954, Univ. Kansas Sci. Bull. 36(2):986). New synonymy
Diagnosis.- This genus is distinguished from Procryphalus Hopkins by the procurved, nonseptate sutures of the antennal club; there is an indistinct basal raised line on the pronotum. A conspicuous biological difference also exists.

Description. - Length 1.65 mm , about 2.6 times as long as wide; color dark brown (only American species considered); sexual differences obscure. Frons broadly convex, conservatively sculptured. Eye elongate-oval, entire but weakly sinuate; finely granulate. Antennal funicle 4 -segmented; club large,
broad, with three procurved sutures indicated by rows of setae, none of them septate. Pronotum with lateral margins rounded, basal raised line obscurely indicated; summit well developed, anterior slope asperate, anterior margin armed. Elytra elongate, weakly striate, conservatively sculptured. Vestiture largely scalelike. Third tarsal segments cylindrical.

Distribution.- E United States (one species); Europe and Asia (about four species).

Biology.- The European species attack cut, broken, or unthrifty branches of Tilia, Fagus and, rarely, other tree genera, where they construct biramose, transverse parental galleries in the cambium region.

Notes.- Schedl (1962:92-94) grouped several genera with Ernoporus. His action appears to have been premature but requires further study (Wood 1972:42).

## Ernoporicus kanawhae Hopkins

Emoporus kanawhae Hopkins, 1915, U.S. Dept. Agric. Rept. 99:35 (Holotype, male; Kanawha Station, West Virginia; U.S. Nat. Mus., 7393); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):987 (description)
Diagnosis.- This species is known only from the type specimen; it is closely allied to, but distinct from, caucasicus Lindemann of Europe.

Male.- Length 1.65 mm , about 2.6 times as long as wide; color dark brown.

Frons convex, finely granulate; pubescence consisting of rather short, moderately abundant hair. Eye sinuate on anterior margin; finely granulate. Antennal club large, subcircular in outline, with three strongly procurved sutures indicated by rows of setae; not septate.

Pronotum rather narrowly rounded in front, armed by four small marginal teeth; summit near middle; anterior slope with numerous rather coarse asperities; posterior area with widely spaced granulate punctures, surface shining, although not entirely smooth; pubescence hairlike in asperate area, short scales behind.

Elytra shining; striae not impressed, punctures very small, distinct, not deep, spaced by about twice their own diameters, spacing irregular; interstriae four times as wide as the striae, punctures rather coarse, shallow,
confused, obscurely subgranulate. Declivity rather steep, convex; striae obsolete. Elytral vestiture consisting of short, rather narrow, abundant, scalelike setae and uniseriate rows of rather widely spaced, scalelike, interstrial bristles, each bristle about one and one-half times as long as wide and about one and onehalf times as long as shorter, more abundant, interstrial scales.
Distribution.- West Virginia.
USA: West Virginia: Kanawha Station, 15-IV-91, in flight, A. D. Hopkins.
Notes.- The above treatment was based on the holotype; it is a male, not a female as stated in the original description.

## Genus Procr yphalus Hopkins

Procryphalus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:33 (Type-species: Procryphalus populi Hopkins = Cryphalus mucronatus LeConte, original designation)
Diagnosis.- This genus is distinguished from other American Cryphalini by the absence of a distinct, raised line on the basal and lateral margins of the pronotum, by the
septate suture 1 of the antenanl club, and by the weakly ascending costal margin of the elytra near the apex.

Description.- Length $1.5-2.2 \mathrm{~mm}$, 2.5-2.8 times as long as wide; color almost black with pale vestiture; sexes similar. Frons broadly convex, conservatively sculptured. Eye elongate-oval, entire; finely granulate. Antennal funicle 4 -segmented; the club elon-gate-oval, weakly constricted at sutures, sutures indicated by rows of setae, 1 septate. Pronotum about equal in length and width; basal and lateral margins rounded, without a raised line; summit in front of middle, anterior slope asperate; anterior margin produced medially and armed by several teeth. Elytra elongate, striate, sculpture conservative; costal margin feebly ascending posteriorly. Vestiture mostly scalelike. Third tarsal segments cylindrical.

Distribution.- N North America and NE Asia; three species, one of which occurs in northeastern Asia.

Biology.- Essentially as described for Trypophloeus.

## Key to the Species of Procryphalus <br> (Adapted from Wood 1954:982)

1. Smaller; frons rather sparsely, shallowly punctured; interstriae more sparsely, finely punctured on posterior three-fourths of disc; Alaska and California to Quebec; Salix; 1.5-1.7 mm .......................................................... 1. utahensis Hopkins

- Larger; frons coarsely, rather deeply punctured; interstriae densely, rather coarsely granulate-punctate over entire disc; Alaska to Colorado and New

1. Procryphalus utahensis Hopkins Figs. 191, 193, 194

Procryphalus utahcnsis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:33 (Holotype, female; Alta, Utah; U.S. Nat. Mus., 7391)
Procryphalus salicis Hopkins, 1915, U'S. Dept. Agric. Rept. 99:33 (Holotype, female; Black Hills, South Dakota; U.S. Nat. Mus., 7390); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):983. Synonymy
Procryphalus accris Hopkins, 1915, U.S. Dept. Agric. Rept. 99:33 (Holotype, female; Albany, Oregon; U.S. Nat. Mus., 7389); Wood, 1975, Great Basin Nat. 35:22. Synonymy
Diagnosis.- In addition to characters summarized in the above key, this species is distinguished from others in the genus by the presence of eight teeth (normally) on the anterior margin of the pronotum, and by the
more coarsely granulate-punctate anterior one-sixth of the elytral interstriae in comparison to the posterior area.
Female.- Length $1.5-1.7 \mathrm{~mm}, 2.7$ times as long as wide, body color dark brown to black.

Frons weakly convex, moderately, shallowly punctured, weakly impressed above epistoma, an indistinct median ridge extending from upper level of eyes to epistomal margin; pubescence consisting of inconspicuous, sparse, fine, long hair. Eye elongate-oval, slightly wider above, about three times as long as wide, entire. Antennal club longer than scape, about 1.60 times as long as wide, with three straight sutures on anterior face, suture 1 septate.

Pronotum about as long as wide, rather strongly produced on anteromedian margin, and armed by eight teeth, two lateral pairs smaller and more widely spaced, often submarginal; summit anterior to middle; asperate in front of and lateral to summit, asperities rather small, abundant; posterior and lateral areas rugose, sparsely, coarsely granu-late-punctate; pubescence consisting of moderately long, hairlike setae on asperate area, and rather short, narrow, scalelike setae on granulate-punctate area.

Elytra shining; striae not impressed, punctures of moderate size and depth, usually separated by distances greater than their own

Fig. 191. Cryphalini tribal and generic characters: 1, 2 , Hypothenemus dissimilis, female (note exposed metepisternum and ascending abdomen), 3, 4, same, male: 5, Pscudopityophthorus pubipennis (note concealed metepisternum and horizontal abdomen); 6, Procryphalus utahensis, anterior face of antennal club, 7, same, posterior face; 8. Trypophloeus ( $=$ Cryphalus of authors) populi, anterior face of antennal club, 9, same, posterior face; 10, Scolytogenes ( = Cryphalomorphus) knabi, anterior face of antennal club, 11, same, posterior face. (Wood 1954:1079.)
diameters (irregular); interstriae as wide or wider than striae, their surface finely, not closely granulate-punctate, rather coarsely granulate near elytral base. Declivity steep, convex; strial and interstrial punctures reduced in size, and not as deep as on disc. Elytral vestiture consisting of abundant, short, confused, semirecumbent, interstrial, scalelike setae and longer, rather sparse, uniseriate rows of scalelike bristles.

Male.-Similar to female.
Distribution.- Alaska and California to Quebec.

ALASKA: Bonanza Creek, 20 miles E Fairbanks, 6-1N77. pheromone trap, T. Egan. CANADA: British Columbia: Copper Mountain. Quebec: Laniel. USA: California: Ft. Bidwell in Modoc Co., Soquel Basin in Madera Co. Colorado: Ft. Collins. Idaho: Minadoka N.F. Oregon: Albany, Dixie Pass. South Dakota: Black Hills. Utah: Alta, Logan Canyon.

Hosts.- Salix scouleriana, S. sp.
Bıology.-Very similar to Trypophloeus striatulus.

Notes.- The above treatment was based on the holotypes of utahensis, salicis, and aceris, and on 38 other specimens.

## 2. Procryphalus mucronatus (LeConte)

Fig. 194
Cryphalus mucronatus LeConte, 1879, U.S. Dept. Int. Geol. Geogr. Survey Bull. 5:518 (Holotype, female; La Veta Pass, Colorado; Mus. Comp. Zool.)
Procryphalus mucronatus: Hopkins, 1915, U.S. Dept. Agric. Rept. 99:33
Procryphalus idahoensis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:34 (Holotype, female; Beaver Canyon, Idaho; U.S. Nat. Mus., 7392); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):985. Synonymy
Procryphalus pouli Hopkins, 1915, U.S. Dept. Agric. Rept. 99:34 (Holotype, female; Tercio, Colorado; U.S. Nat. Mus., 7393); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):985. Synonymy
Diagnosis.- This species is distinguished from utahensis Hopkins by the larger size, by the more coarsely, closely punctured frons, by the more strongly produced anterior margin of the pronotum, which is armed by only six teeth, and by the more coarsely, closely granulate-punctate interstriae.

Female.- Length $1.8-2.2 \mathrm{~mm}, 2.54$ times as long as wide, body color black.

Frons slightly convex to indistinctly impressed, coarsely, closely, deeply punctured, weakly impressed above epistoma, an indistinct median ridge extending from upper
level of eyes to epistomal margin; pubescence consisting of inconspicuous, sparse, fine, long hair. Eye elongate-oval, slightly wider above, entire. Antennal club longer than scape, about 1.62 times as long as wide, with two straight sutures on the anterior face, suture 1 septate.

Pronotum about as long as wide; strongly produced on anteromedian margin and armed by six teeth, lateral pair much smaller and more widely spaced, located at base of produced area; summit anterior to middle, asperate in front of and to sides of summit, asperities rather small, abundant; posterolateral areas rather coarsely, strongly granulate-punctate. Pubescence consisting of moderately long hairlike setae on asperate area and rather short, narrow, scalelike setae on granulate-puncțate area.

Elytra shining; striae not impressed, punctures of moderate size, not always distinct or regularly spaced; interstriae about equal in width to striae, surface coarsely, closely gran-ulate-punctate. Declivity steep, convex; strial and interstrial punctures reduced in size and not as deep as on disc. Elytral vestiture consisting of abundant, short, confused, semirecumbent, interstrial, scalelike setae, and longer, rather sparse, uniseriate rows of scalelike, interstrial bristles.

Male.- Similar to female.
Distribution.- Alaska to E Nevada, Colorado, and New Mexico.

ALASKA: Hope. 1978, pheromone trap, R. A. Werner. CANADA: Bright (1976:112) adds Alberta and British Columbia. USA: Colorado: Camp Creek in Jackson Co., Manitou, Norwood, Ouray, Poudre Canyon in Larimer Co., Ridgeway, Tercio. Idaho: Beaver Canyon. Franklin Basin in Franklin Co. Nevada: Lehman Creek at Mt. Wheeler. New Mexico: Sandia Mts., Sierra Blanca Mt. Utah: Logan Canyon, Logan Dry Canyon, Payson Canyon. Provo Canyon.

## Host.- Populus tremuloides.

Biology. - The smooth bark of the bole of large, dying, standing trees is selected for attack. The habits are reviewed by Petty (1977).

Notes.- The above treatment was based on the holotypes of mucronatus, idahoensis, and populi and on 249 other specimens.

## Genus SCOLYTOGENES Eichhoff

Scolytogenes Eichhoff, 1878, Mem. Soc. Roy. Sci. Liége (2)8:475, 497 (Type-species: Scolytogenes darwinii Eichhoff, monolasic)

Lepicerus Eichhoff, 1878 (nec Motschulsky, 1855), Mem. Soc. Roy. Sci. Liége, (2)8:476, 501 (Type-species: Lepicerus aspericollis Eichhoff, monobasic); Wood, 1980, Great Basin Nat. 40:95. Synonymy
Cryphalomorphus Schaufuss, 1890, Tijdschr. Ent. 34:12 (preprint 1890, Martinus Nijhoff, Haag) (Typespecies: Cryphalomorphus communis Schaufuss, monobasic); Schedl, 1940, Mitt. Münchener Ent. Ges. 30(2):583-591. Synonymy
Letanerella Reitter, 1913, Wiener Ent. Zeit. 32:68 (Type-species: Bostrichus jalapae Letzner, monobasic): Schedl. 1940, Mitt. Münchener Ent. Ges. 30(2):583-591. Synonymy
Hypothenoides Hopkins, 1915, U.S. Dept. Agric. Rept. 99:11 (Type-species: Hypothenoides parvus Hopkins, original designation); Schedl, 1954, Philippine J. Sci. 83:138. Synonymy
Ernoporides Hopkins, 1915, U.S. Dept. ムgric. Rept. 99:34 (Type-species: Ernoporides floridensis Hopkins = Ernoporides knabi Hopkins, original designation); Schedl, 1940, Mitt. Münchener Ent. Ces. 30(2):583-591. Synonymy
Neocryphalus Eggers, 1922, Ent. Blätt. 18:169 (Typespecies: Neocryphalus usagaricus Eggers, monobasic): Schedl. 19.40, Mitt. Münchner Ent. Ces. 30 2):583-591. Synonymy
Negritus Eggers, 1923, Ent. Meded. 7:141 (Type-species: Negritus ater Eggers, present designation): Schedl, 1957, Ann. Mag. Nat. Hist. (12)10:152. Synonymy
Lepicerimus Hinton, 1936, Ann. Mag. Nat. Hist. (10)17:472 (Replacement name for Lepicerus Eichhoff).
Cylindrotomicus Eggers, 1936, Ann. Mag. Nat. Hist. (10)17:633 (Type-species: Cylindrotomicus squamulosus Eggers, monobasic); Schedl, 1957. Ann. Mag. Nat. Hist. (12)10:152. Synonymy
Diagnosis. - In the American fauna this $^{\text {fan }}$ genus is most closely allied to Ernoporicus Berger, but it is distinguished by the absence of sutures on the antennal club except for a septum in the lateral half of suture 1 , by the rounded lateral margins of the pronotum on which there is an obscure, fine raised line on the basal third, and by biological characters.

Description.- Length 0.9-1.9 mm, 2.3-2.7 times as long as wide; color dark brown to black, with pale vestiture. Frons broadly convex, conservatively sculptured. Eye elongate, entire to shallowly, very broadly emarginate; finely granulate. Antennal funicle 4 -segmented; club moderately large, devoid of sutures except for strongly angulate septum in lateral half of suture 1 . Pronotum with a fine raised line on lateral and basal margins; summit at or slightly in front of middle, anterior slope asperate; anterior margin rather broadly rounded, armed.

Elytra elongate, striae distinct or not; sculpture conservative. Vestiture of hair and scales.

Biology.- These monogamous beetles infest various vines. The parental tumnels evidently consist of an irregular, often branched
chamber extending through one or more levels or concentric layers of host tissue. The larval mines are irregular and evidently wander among the fibers of the stem. The heavy infestations of samples examined have made accurate observations impossible.

## Key to the Species of Scolytogenes

1. Fine strial hair and all interstrial scales in uniseriate rows; pronotal disc with fine, isolated granules in lateral areas as well as behind summit, punctures absent; anterior area of pronotum devoid of marginal or submarginal teeth, asperities confined to upper half of anterior slope; Honduras to Costa Rica; small vines; 0.8-0.9 mm
2. parvatis Wood

- Interstrial setae more abundant, many or most not in rows; pronotum with lateral areas of disc punctured, granules usually absent except behind summit; anterior margin or submargin armed by two or more denticles; larger
2(1). Strial punctures rather large, deep, almost as wide as interstriae, spaced within a row by average distances equal to less than half diameter of a puncture; pronotal vestiture entirely of hairlike setae (occasional scales on extreme posterior margin in one species)
- Strial punctures small, shallow, diameters equal to less than half width of an interstriae, spaced within a row by average distances greater than diameter of a puncture 4
3(2). Anterior margin of pronotum armed by four to eight teeth; declivital striae feebly impressed, interstriae indistinctly convex, interstrial granules small; erect interstrial scales more slender, about eight times as long as wide; Guatemala; liana; 1.4-1.7 mm

2. setifer Wood

- Anterior margin of pronotum armed by two large marginal teeth; striae on posterior part of disc and on declivity rather strongly impressed, interstriae conspicuously convex, interstrial granules moderately large; erect interstrial scales wider, averaging about four to six times as long as wide; Puebla to Oaxaca; small tree, $1.7-1.9 \mathrm{~mm}$
4(2). Interstrial ground vestiture of dise scalelike, almost as wide as erect bristles in median rows, on declivity almost as wide as long, not tapered; punctures on disc bearing erect interstrial bristles not at all granulate; anterior margin of pronotum regularly armed by two coarse teeth; Jalisco and Guanajuato to Chiapas; small tree; $1.2-1.5 \mathrm{~mm}$
- Interstrial ground vestiture on disc slender, almost hairlike, on declivity scalelike, each scale more than twice as long as wide and narrowed toward its apex; punctures on disc bearing erect bristles, very finely granulate; anterior margin of pronotum sometimes irregularly armed by up to eight small teeth
5(4). Strial punctures very small and in rows to completely confused with those of interstriae; disc of pronotum shining; erect declivital interstrial scales uniformly shorter, each about three to four times as long as wide; Nayarit and S Florida to Venezuela; vines; $1.1-1.5 \mathrm{~mm}$

5. knabi (Hopkins)

- Strial punctures distinctly larger than those of interstriae, in definite rows; disc of pronotum at least partly reticulate; erect, declivital interstrial scales less uniform in length, each four to six times as long as wide

6(5). Punctures on pronotal disc and discal striae very slightly smaller; strial punctures on declivity only slightly wider than adjacent interstrial granules; interstrial bristles on lateral areas of basal half of disc similar to one another; Puebla to Oaxaca; small tree; $1.3-1.5 \mathrm{~mm}$
6. trucis Wood

- Punctures on pronotal disc and discal striae slightly larger; strial punctures on declivity at least twice as wide as adjacent interstrial granules; interstrial bristles on basal half of interstriae 9 and 10 longer and distinctly more slender than others; Mexico; Exogonium jalapa; 1.7-1.8 mm 7. jalapae (Letzner)

## 1. Scolytogenes parvatis (Wood)

Cryphalomorphus parcatis Wood, 1974, Brigham Young Univ. Sci. Bull. 19(1):17 (Holotype, female; La Lima, Honduras; Wood Coll.)
Diagnosis.- This unique species is characterized by the small size, by the unarmed anterior margin of the pronotum, and by the uniseriate rows of strial hair and interstrial scales. It is much more likely to be confused with species of Hypothenemus than with other Scolytogenes species.

Female.- Length $0.8 \mathrm{~mm}, 2.6$ times as long as wide; color very dark brown with pale scales.

Frons moderately convex, almost smooth, with rather abundant, very small punctures; vestiture inconspicuous. Eye elongate, very shallowly, broadly emarginate. Antennal scape short; club subcircular, septum poorly developed, almost transverse.

Pronotum 1.0 times as long as wide; widest slightly behind middle, sides moderately arcuate but converging only slightly to anterolateral angles, then rather abruptly converging to form subangulate, broadly rounded anterior margin; anterior margin unarmed; summit distinct, in front of middle; anterior slope rather finely asperate; posterior areas obscurely subreticulate, with rather fine, isolated granules of moderate abundance in lateral and dorsal areas. Vestiture of equally abundant short hair and scales in posterior areas, only hair on anterior half.

Elytra 1.6 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two thirds, rather narrowly rounded behind; striae not impressed, punctures uniseriate, small, rather shallow; interstriae as wide as striae, rather smooth, punctures slightly smaller than those of striae, not clearly defined. Declivity narrowly convex, rather steep; punctures slightly smaller than on disc. Vestiture of uniseriate rows of fine,
short, recumbent strial hair, and uniseriate rows of erect interstrial scales; each scale about four times as long as wide, widest at its apex, spaced within a row and between rows by distances slightly shorter than length of a scale.

Distribution.-Honduras to Costa Rica.
honduras: La Lima, 5-V-64, 100 m , No. 581, Cestrum scandens, S. L. W'ood. COSTA RICA: Guápiles, Limón, 22-VIII-66, 100 m , No. 106, leguminous vine, S. L. Wood.

Hosts.- Cestrum scandens and a leguminous vine.

Biology.- Unknown except that it breeds in small vines.

Notes.- The above treatment was based on the type series of three specimens.

## 2. Scolytogenes setifer (Wood)

Cryphalomorphus setifer Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):18 (Holotype, female; Volcán Pacaya, Esquintla, Guatemala; Wood Coll.)
Diagnosis.- This species is distinguished from hirtus Wood by the smaller size, by the presence of four to eight teeth on the anterior margin of the pronotum, by the less strongly impressed striae, and by the more slender interstrial scales.

Female.- Length $1.4-1.7 \mathrm{~mm}, 2.5$ times as long as wide; color very dark brown, with pale vestiture.

Frons broadly convex above, somewhat flattened below, a weak transverse impression just above epistoma; surface strongly reticulate, punctures fine, rather obscure, moderately close; vestiture inconspicuous. Eye entire, not at all sinuate. Antennal scape elongate; club rather large, ovate, suture 1 septate on lateral half, its procurved groove extending to median margin.

Pronotum 1.0 times as long as wide; widest just behind middle, sides weakly arcuate on
posterior two-thirds, broadly rounded in front; anterior margin armed by four to eight small teeth; summit very slightly in front of middle; posterior areas coarsely, very closely punctured. Vestiture of short, stout, abundant hair.

Elytra 1.6 times as long as wide, 1.7 times as long as pronotum; outline as in parvatus; striae very feebly impressed, punctures rather coarse, moderately deep; interstriae very slightly wider than striae, smooth, punctures fine, deep, close, strongly confused. Declivity rather narrowly convex, steep; strial punctures slightly smaller, deeper; interstriae each with a uniseriate row of very fine granules. Vestiture of abundant, short ground cover, setae hairlike at base, becoming scalelike on declivity, and rows of erect interstrial bristles; each erect bristle as long as distance between rows and between scales within a row, those on declivity stouter, almost scalelike, about eight times as long as wide.

Male.-Similar to female except frontal impression slightly deeper.

Distribution.- Guatemala.
GUATEMALA: Guatemala City, $30-\mathrm{V}-64,1300 \mathrm{~m}$, No. 641, liana, S. L. Wood; Volcán Pacaya, 1-VI-64, 1300 m , No. 665, liana, S. L. W'ood.

Biology.- As described for the genus.
Notes.- The above treatment was based on the type series of 63 specimens.

## 3. Scolytogenes hirtus (Wood)

Cryphalomorphus hirtus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):18 (Holotype, female; 16 km S Oaxaca, Oaxaca, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from setifer Wood by the larger size, by the presence of only two teeth on the anterior margin of the pronotum, by the more strongly impressed interstriae, and by the stouter interstrial scales.

Female.- Length $1.7-1.9 \mathrm{~mm}, 2.3$ times as long as wide; color dark brown, almost black.

Frons as in setifer except transverse impression on lower half much stronger, and punctures much coarser but shallow. Antennal club as in setifer but slightly wider. Pronotum as in setifer but anterior margin armed by only two teeth and punctures in posterior area not as deep; a few scales sometimes present on posterior margin in front of scutellum.

Elytra 1.4 times as long as wide; sides almost straight and parallel on basal threefourths, broadly rounded behind; striae moderately impressed on posterior half of disc, punctures rather coarse, deep; interstriae slightly wider than striae, moderately convex toward declivity, punctures on dise small, close, confused, armed near declivity by median rows of small granules. Declivity very broadly convex, steep; sculpture as on posterior part of disc except interstriae slightly narrower, granules much larger. Vestiture of abundant ground cover of short scales and median interstrial rows of erect scales; erect scales little longer than ground cover on basal half of disc, more than twice as long on declivity, each scale almost as long as distance between rows and similarly spaced within a row, each about four to five times as long as wide.

Male.- Similar to female except transverse frontal impression slightly deeper.

Distribution.- Puebla and Oaxaca.
MEXICO: Oaxaca: 16 km S Oaxaca, 6-VII-53, S. L. Wood. Puebla: 6 km S Atlixco, 14-VI-67, 2300 m , No. 31, S. L. Wood. All taken from a small tree with simple leaves and a loosely layered structure of woody tissues in the branches.
Notes.- The above treatment was based on the type series of eight specimens.

## 4. Scolytogenes rusticus (Wood)

Cryphalomorphus rusticus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):18 (Holotype, female; 33 km N Juchitlan, Jalisco, Mexico; Wood Coll.)
Diagnosis.- Distinguished from knabi (Hopkins) by the two teeth arming anterior margin of the pronotum, by the much wider, scalelike ground vestiture on the anterior half of the elytral disc, and by the absence of interstrial granules on the disc.

Female.- Length $1.2-1.5 \mathrm{~mm}, 2.6$ times as long as wide; color dark brown, almost black.

Frons as in knabi except transverse impression much less strongly developed, punctures coarser, deeper. Eye, antenna, and pronotum as in knabi except anterior margin of pronotum armed by two coarse teeth and punctures on pronotal dise distinctly larger.

Elytra as in knabi except discal interstriae larger, deeper; declivital striae greatly reduced; interstrial ground vestiture at base of elytra of slender scales, each scale as wide as
those in erect rows, on declivity each scale as wide as long; erect scales on declivity slightly longer than in knabi.

Male.- Similar to female in all respects.
Distribution.- Jalisco and Guanajuato to Chiapas.

MEXICO: Chiapas: 11 km S Teopisca, 23-V-69, D. E. Bright. Guanajuato: Lagos, 11-VI-65, 2100 m , No. 44, S. L. Wood. Jalisco: 13 km N Juchitlán, 3-VII-65, 1300 m , No. 185, S. L. Wood. Michoacán: 11 km SE Tuxpan, 16-Vll-53, S. L. Wood. All were taken from the same host as hirtus.

Biology.-Specimens were taken at all layers of the host from recently broken branches.

Notes.- The above treatment was based on the type series of 27 specimens and on 8 other specimens.

Part of the series from Michoacán is intermediate between this species and trucis. The two forms breed in the same host in rather widely separated geographical areas. Perhaps future collecting will make it necessary to recognize them as no more than subspecies.

## 5. Scolytogenes knabi (Hopkins) Figs. 191, 193, 194

Emoporides knabi Hopkins, 1915, U.S. Dept. Agric. Rept. 99:34 (Holotype, female; Cordoba, Mexico; U.S. Nat. Mus., 7595 )

Cryphalomorphus knabi: Schedl, 1940, Mitt. Münchner Ent. Ges. 30:588
Ernoporides floridensis 1Iopkins. 1915. U.S. Dept. Agric. Rept. 99:34 (Holotype, female; Biscayne, Florida; U.S. Nat. Mus., 7394); Wood, 1966, Great Basin Nat. 26:23. Synonymy
Hypothenemus ritchici Sampson, 1918, Bull. Ent. Res. 8:295 (Female syntypes; Jamaica; British Mus. Nat. Hist.); Wood, 1966, Great Basin Nat. 26:23. Synonymy
Cryphalomorphus caraibicus SchedI, 1951, Dusenia 2:96 (Syntypes, Cuadeloupe; Schedl Coll.); Wood, 1966, Great Basin Nat. 26:23. Synonymy
Cryphalomorphus minutissimus Schedl, 1951, Dusenia 2:97 (Holotype, male; Env. de Trois Rivières, Guadeloupe; Schedl Coll.); Wood, 1977, Great Basin Nat. 37:385. Synonymy
Cryphalomorphus subtriutus Schedl, 1952, Dusenia 3:360 (Holotype, sex?; Mexico; Schedl Coll.); Wood. 1966, Great Basin Nat. 26:23. Synonymy
Diagnosis.- This abundant species is distinguished from rusticus Wood and trucis Wood by the very small or obsolete discal strial punctures, by the smaller pronotal punctures, and by the somewhat less abundant, much more slender interstrial ground vestiture, particularly on the basal half of the disc.

Female.- Length $1.1-1.5 \mathrm{~mm}, 2.6$ times as long as wide; color dark brown to black, vestiture pale.

Frons convex above, moderately, transversely impressed on lower half; surface rather coarsely reticulate above, becoming almost smooth in median area below; punctures moderately coarse, rather shallow, much smaller in median area below; vestiture inconspicuous. Eye and antenna as in setifer.

Pronotum as long as wide; widest behind middle, sides weakly arcuate and converging very slightly on basal two-thirds, broadly rounded in front; anterior margin varying within a series from unarmed to a med by one to eight teeth (usually irregular in size and position; summit well developed, at or just in front of middle; posterior area smooth except for occasional minutely rugulose areas, a few isolated granules behind summit, remaining area with fine, poorly defined punctures. Vestiture of fine hair, with erect scales intermixed on basal third.

Elytra 1.6 times as long as wide, 1.7 times as long as pronotum; outline as in privatus; strial punctures fine, shallow, often indistinguishable from those of striae; interstriae at least twice as wide as striae, almost smooth, punctures fine, confused, moderately close, those on posterior half of dise bearing erect scales, very minutely granulate. Declivity rather narrowly convex; steep; strial punctures larger and deeper than on disc; interstrial granules larger. Vestiture of fine, short strial hair and a few similar interstrial setae in ground vestiture, and rows of longer, erect, interstrial scales; each scale on disc slightly shorter than distance between rows or between scales within a row, each about three times as long as wide, slightly longer on declivity and about four times as long as wide.

Male.- Similar to female except transverse frontal impression usually much weaker.
Distribution.- Nayarit and S Florida to Venezuela.

USA: Florida: Biscayne, Miami, Plantation Key, Sugar Loaf Key. MEXICO: Chiapas: Chiapa de Corzo. Nayarit: Los Corchos. Oaxaca: 11 km N Matías Romero. Veracruz: Cordoha, 5 km W Jáltipan. GUATEMALA: Esquintla. Guatemala City, Lago Amatitlan, Rodeo, Volcán de Agua. HONDUBAS: La Ceiba, La Lima. OTHER COUNTRIES: Tortola in British West Indies,

Cuba, Dominican Republic, Guadeloupe, Jamaica, Venezuela.

Hosts.- Caloncition tamnifolium, Candiosperma holacobium, Ipomeoa pes-carpae, Seriania sp., and several other vines and small lianas.

Biology.- Recently cut and dying vines usually less than 3 cm in diameter are selected for attack. All tissues in the stem are perforated. The irregular gallery patterns could not clearly be determined.

Notes. - The above treatment was based on the holotypes of knabi, floridensis, minutissimus, and subtriatus, on syntypes of ritchiei and caraibicns, and on 223 other specimens.

There are slight variations in the size and position of strial punctures on the disc, in the arrangement of serrations on the anterior margin of the pronotum, and in the relative abundance of setae in the ground vestiture in long series. It appears from the number of synonyms of this species that some of these variations have been incorrectly interpreted as characterizing species.

## 6. Scolytogenes trucis (Wood)

Cryphalomorphus trucis Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):19 (Holotype, female; 16 km or 10 mi S Oaxaca, Oaxaca, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from rusticus Wood by the coarser, strial punctures on the elytral declivity, by the more slender discal interstrial ground vestiture, and by the different armature on the anterior margin of the pronotum.

Female.- Length $1.3-1.5 \mathrm{~mm}, 2.6$ times as long as wide; color very dark brown, almost black, vestiture pale.

Frons, eye, and antenna as in rusticus except frontal punctures larger, deeper. Pronotum as in rusticus except posterior areas reticulate, and anterior margin armed by about four to eight irregularly placed teeth.

Elytra as in rusticus except strial punctures slightly larger, deeper; interstrial punctures minute but evident; discal ground vestiture near base of elytra proportionately much narrower than adjacent erect scales; strial punctures on declivity average much larger.

Male.-Similar to female.
Distribution.- Puebla and Oaxaca.

MEXICO: Oaxaca: 16 km S Oaxaca, 6-VIl-53, 1700 m . Puebla: 11 km S Atlixco, 13-VIl-53, $1000 \mathrm{~m} ; 6 \mathrm{~km}$ S Atlixco, 14-V1-67, 2300 m , No. 31. All taken from the same host as hirtus by me.

Biology.- As in hirtus.
Notes.- The above treatment was based on the type series of 37 specimens.

The minor variations in this species and in rusticus, their close relationship, their allopatric distributions, and the fact that they utilize the same host species suggests that this species and rusticus represent no more than subspecies of one another. Nevertheless, until more material is available for study from intermediate localities, they should be recognized as being distinct.

## 7. Scolytogenes jalapae (Letzner)

Bostrichus jalapae Letzner, 1848, Uebers. Schlesischen Ges. Vaterland Kuture, p. 99 (Syntypes, not located).
Diagnosis.- This species is distinguished from trucis Wood by the larger size, by the much longer, more slender bristles on the basal half of interstriae 9 and 10 , and by other characters cited below.

Female.- Length $1.7-1.8 \mathrm{~mm}, 2.5$ times as long as wide; color dark brown.

Frons, eye, antenna, and pronotum as in trucis, except punctures on posterior area of pronotum distinctly larger.

Elytra as in trucis except strial punctures distinctly larger and deeper on both dise and declivity; interstrial granules on dise slightly larger, extending almost to base, punctures averaging smaller and slightly less numerous; interstrial granules on declivity smaller but almost as high; erect interstrial scales slightly longer.

Male.- Similar to female.
Distribution.- "Mexico."
This species has been intercepted numerous times in Jalapa root (presumably Exogonium jalapa) imported from Mexico. Specimens are labeled with the port of interception, but the source of the plant material is not recorded.

Host.- Presumably Exogonium jalapa.
Biology.- The roots of the host are presumably infested at the time of harvest.

Notes.- The above treatment was based on several hundred specimens intercepted at New York. Type material has not been located.

# Genus CRyphalus Erichson 

Cryphalus Erichson, 1836, Archiv Naturgesch. 2(1):61 (Type-species: Bostrichus asperatus Gyllenhal, subsequent designation by Thomson, 1859, Skandinaviens Coleoptera Synoptiskt Bearbetade 1:147)
Taenioglyptes Bedel, 1888, Ann. Soc. Ent. France, Hors. ser. 6:398 (Type-species: Bostrichus abietis Ratzeburg = Bostrichus asperatus Gyllenhal, original designation); Wood, 1972, Great Basin Nat. 32:40. Synonymy
Diagnosis.- This genus is distinguished from the closely allied Hypocryphalus Hopkins by the 4 -segmented antennal funicle, by the large, aseptate club with three recurved sutures on the anterior face indicated by impressed lines and rows of setae, and by the broad, emarginate third tarsal segments.

Description.- Length $1.4-2.1 \mathrm{~mm}$, 2.3-2.4 times as long as wide; color brown; sexes similar. Frons broadly convex, conservatively sculptured; eye emarginate, finely granulate. Antennal funicle 4 -segmented; club large, oval, a slight constriction at each of three nonseptate recurved sutures. Pronotum with basal and posterior third of lateral margins marked by a fine, raised line;
summit well developed, anterior slope coarsely asperate; anterior margin armed; vestiture hairlike. Elytra finely striate, conservatively sculptured; costal margins rather strongly ascending near apex; vestiture of hair and abundant scales. Third tarsal segments broad, emarginate.

Distribution.-N North America, Europe, and Asia to Australia; four species occur in the United States and Canada; several hundred nominate species from the Asian-Australian area have been assigned to the genus at various times.

Biology.- These monogamous, phloeophagous species construct a simple, cave-type parental chamber in which eggs are deposited. The larval mines are separate and wander at random in the phloem tissues. The American species breed in shaded-out or broken branches on living trees or in the limbs or boles of small suppressed trees.

Notes. - This group is in serious need of a comprehensive worldwide revisional study. The generic limits are not clearly defined, and synonyms abound in the species from the Asian-Australian area.

## Key to the Species of Cryphalus

1. Elytral declivity with widely spaced, uniseriate rows of hairlike interstrial bristles, each bristle at least one-half as long as distance between rows of bristles

- Interstrial bristles on declivity inconspicuous or absent, much shorter than onehalf distance between rows of bristles
2(1). Declivital bristles distinctly longer than distance between rows of bristles; British Columbia to California; Abies, Pseudotsuga, etc.; $1.6-1.9 \mathrm{~mm}$

1. pubescens Hopkins

- Declivital bristles one-half as long as distance between rows of bristles; Pennsylvania to North Carolina; Picea rubens; $1.6-2.0 \mathrm{~mm}$

2. rubentis Hopkins

3(2). Strial punctures indistinctly impressed, obsolete on declivity; posterolateral areas of pronotum granulate; Minnesota and Maine to North Carolina; Abies; $1.5-2.1 \mathrm{~mm}$ 3. ruficollis fraseri Hopkins

- Strial punctures more strongly impressed, usually extending to declivity; posterolateral areas of pronotum granulate-punctate; Alaska, California, and Nuevo León to Quebec and Maine; Abies, Picea; 1.4-2.0 mm

4. ruficollis ruficollis Hopkins

## 1. Cryphalus pubescens Hopkins <br> Fig. 192, 193

Cryphalus pubescens Hopkins, 1915, U.S. Dept. Agric. Rept. 99:40 (Holotype, female; Port Williams, Washington; U.S. Nat. Mus., 7405)
Cryphalus subconcentralis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:40 (Holotype, female, Astoria, Oregon; U.S. Nat. Mus., 7596); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1003. Synonymy
Diagnosis.- This species is more closely allied to piceae Ratzeburg, of Europe, than to Nearctic species. It is distinguished from other American species by the very long interstrial setae and by the smoother, more finely punctured posterolateral areas of the

$$
\#
$$ rather closely punctured, rather coarsely reticulate over a larger area; pubescence consisting of inconspicuous, sparse, fine hair of medium length, and a more conspicuous ventrally directed epistomal brush.

Pronotum 0.83 times as long as wide; anterior margin rather narrowly rounded, bearing four to eight marginal teeth that decrease in size laterally; summit on basal third; anterior slope asperate, asperities rather abundant, large, usually broad, occasionally arranged in one or more subconcentric rows, particularly near summit; posterior and lateral areas coarsely, closely, deeply punctured, granulate behind summit and near lateral margins; pubescence consisting of rather short, fine, recumbent hair, coarse on asperate area.

Elytra shining; striae not impressed, punctures fine, shallow, distinct, separated by distances greater than their own diameters; interstriae two to three times as wide as striae, punctures fine, abundant, confused. Declivity rather steep, convex; striae more obscure than on disc. Elytral vestiture consisting of uniseriate rows of short, hairlike strial setae; abundant, confused, short, interstrial, scalelike setae; and uniseriate rows of widely spaced, very long, slender, interstrial, hairlike bristles, each bristle distinctly longer than distance between rows of bristles.

Male.-Similar to female.
Distribution.- The Pacific Coast Range from British Columbia to California.

CANADA: British Columbia: Pender Harbor, Saanichton. Sidney, Vancouver. USA: California: Eureka, Mt. Tamalpais in Marin Co., Muir Woods. Oregon: Astoria, Marshfield, Olympic N.F., Santiam N.F. Washing. ton: Ft. Flagler, Port Townsend, Port Williams.

Hosts.-Abies grandis, Pinus lambertiana, Pseudotsuga menziesii, Sequoia sempervirens.

Biology. - As described for the genus.
Notes.- The above treatment was based on the holotypes of pubescens and subconcentralis and on 38 other specimens.

## 2. Cryphalus rubentis Hopkins

Cryphalus mbentis Hopkins. 1915, U.S. Dept. Agric. Rept. 99:40 (Holotype, female; Pocahontas Co., West Virginia; U.S. Nat. Mus., 7404)
Diagnosis.- This species is somewhat intermediate between pubescens Hopkins and ruficollis Hopkins, but it is distinguished by the granulate posterolateral areas of the pronotum, by the obsolete strial punctures, and by the interstrial bristles, which are very long on the elytral disc and only one-half as long as the distance between rows of bristles on the declivity.

Female.- Length $1.60-1.95 \mathrm{~mm}, 2.3$ times as long as wide, color light brown.

Frons convex, with a weak transverse impression between eyes and usually with a short, indistinct, median, longitudinal elevation above epistoma; surface coarsely, shallowly, rather closely punctured at sides; rather coarsely reticulate over a larger area; pubescence consisting of inconspicuous, sparse, fine hair of medium length, and a more conspicuous ventrally directed epistomal brush.

Pronotum 0.86 times as long as wide; anterior margin rather narrowly rounded, bearing from four to eight teeth, four median ones usually subequal in size, lateral ones reduced; summit on basal third; asperate in front of summit, asperities rather abundant, large, usually narrow, confused; posterior and lateral areas coarsely, closely granulate, punctures not evident; pubescence consisting of rather short, fine, recumbent hair, coarse on asperate area.

Elytra shining; striae feebly or not at all impressed, punctures obscure; interstrial punctures abundant, confused, very fine, surface almost smooth except for punctures. Declivity rather steep, convex; striae obsolete. Elytral vestiture consisting of uniseriate rows of short, hairlike, strial setae; abundant, confused, short, interstrial, scalelike setae; and uniseriate rows of widely spaced, long, slender, interstrial, hairlike bristles, each bristle on disc about as long as distance between rows of bristles, those on declivity about half as long.

Male- Similar to female.
Distribution.- Pennsylvania to North Carolina.

U'SA: North Carolina: Clingman's Dome in Great Smoky Mountains N.P., 19-VII-51, Picea rubens, S. L. Wood. Pennsylvania: Pocono Lake. West Virginia: Pocahontas Co., 6-V-93, Hopk. W. Va. 6258, Picea rubens, A. D. Hopkins: Randolph Co., Picea.

Host.- Picea rubens.
Biology.- As described for the genus. Specimens were taken from the bole of a small tree.

Notes.- The above treatment was based on the holotype of rubentis and on 30 other specimens.

## 3. Cryphalus ruficollis fraseri Hopkins

Cryphalus fraseri Hopkins, 1915, U.S. Dept. Agric. Rept. 99:40 (Holotype, female, Pisgah Ridge, North Carolina: UT.S. Nat. Mus., 7402)
Cryphalus halsameus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:4I Holotype, female; Camp Caribou, Maine; U.S. Nat. Mus., 740I); Wood, 1954, Univ. Kansas Sci. Bull. $36(2): 1010$. Synonymy
Diagnosis.- This species is distinguished from ruficollis Hopkins by the obsolete strial punctures and by the more completely granulate posterolateral areas of the pronotum. It resembles rubentis, but the long interstrial bristles on the declivity are absent, the discal bristles are much shorter, and the surface of the elytra is rugose.

Female.- Length $1.5-2.1 \mathrm{~mm}, 2.35$ times as long as wide, body color brown.

Frons convex, with a weak transverse impression between eyes and usually with a short, indistinct, median, longitudinal elevation near the epistoma; surface coarsely, shallowly, rather closely punctured at sides, rather coarsely reticulate over a larger area; pubescence consisting of inconspicuous, sparse, fine hair of medium length, and a more conspicuous, ventrally directed epistomal brush.

Pronotum 0.82 times as long as wide; anterior margin rather narrowly rounded, armed by four to eight teeth, four median ones usually subequal in size, lateral ones reduced; summit on basal third; asperate in front of summit, asperities rather abundant, large, usually narrow, confused; posterior and lateral areas closely, rather coarsely granulate, punctures usually evident only near asperate area; pubescence consisting of rather short, fine, recumbent hair, coarse on asperate area.

Elytra shining; striae weakly or not at all impressed, punctures obsolete; interstriae
finely, closely granulate-punctate. Declivity rather steep, convex; striae obsolete; interstriae finely punctured. Elytral vestiture consisting of uniseriate rows of short, hairlike, strial setae, abundant, confused, short, interstrial scalelike setae, and uniseriate rows of widely spaced, rather long, slender, interstrial, hairlike bristles on disc, each bristle about half as long as distance between rows of bristles, obsolete on declivity.

Male.- Similar to female.
Distribution. - Minnesota and Maine to North Carolina.
CANADA: Quebec: Ile Perrot. Howick, Memphremagog, Monte Bello, St. Anne's. USA: Maine: Bar Harbor, Camp Caribon, Orono. Michigan: Charlevoix Co. Minnesota: Itasca Co. New York: Cranberry Lake, Green Co., lthaca. North Carolina: Clingman's Dome in Great Smoky Mountains N.P., Pisgah Ridge. Pennsylvania: Pocono Lake.

Hosts.- Abies balsamea, A. fraseri.
Biology.-As described for the genus. A series was taken from the bole of a small, suppressed tree.

Notes.- The above treatment was based on the holotypes of both fraseri and balsameus and on 90 other specimens.

As more specimens of this subspecies are taken in the prairie provinces of Canada, it will be most surprising if it does not completely intergrade with ruficollis. The only significant difference appears to be in the depth, number, and spacing of strial punctures; a similar character gradient involving this same feature occurs in the European asperatus (Gyllenhal).

## 4. Cryphalus ruficollis ruficollis Hopkins Fig. 176, 194

Cryphalus ruficollis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:40 (Holotype, female, Alta, Utahi; U.S. Nat. Mus., 7403)
Cryphalus approximatns Hopkins, 1915, U.S. Dept. Agric. Rept. 99:41 (Holotype, female; Sandpoint, Idaho; U.S. Nat. Mus., 7400); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1005. Synonymy
Cryphalus grandis Chamberlin, 1917, Canadian Ent. 49:323 (Lectotype, female; Corvallis, Oregon; Canadian Nat. Coll., designated by Bright, 1967, Canadian Ent. 99:681); Wood. 1954, Univ. Kansas Sci. Bull. 36(2):1005. Synonymy
Cryphalus amabilis Chamberlin, 1917, Canadian Ent. 49:321 (Lectotype, female; Elk Lake, Oregon; Canadian Nat. Coll., designated by Bright, 1967, Canadian Ent. 99:681); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1005 (subsp. of ruficollis)

Cryphalus canadensis Chamberlin, 1918, in Swaine, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(2):88 (Holotype, female; Roger's Pass British Columbia; Canadian Nat. Coll.); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1006. Synonymy
Cryphalus mainensis Blackman, 1922, New York St. Coll. For., Syracuse, Tech. Pub. 16:126 (Holotype, female; Orono, Maine, U.S. Nat. Mus.); Wood, 1954, Univ. Kansas Sci. Bull. 36(2): 1006. Synonymy
Taenioglyptes ruficollis coloradensis Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1008 (Holotype, female; 7 miles N Grand Canyon N.P., Arizona; Snow Ent. Mus., Univ. Kansas). New synonymy
Diagnosis.- This subspecies is distinguished from ruficollis fraseri Hopkias by the distinctly impressed strial punctures and by the less granulate posterolateral areas of the pronotum.

Female.- Length $1.45-1.85 \mathrm{~mm}, 2.3$ times as long as wide, body color dark brown.

Frons weakly convex, with a short, often indistinct, median, longitudinal elevation near epistoma; surface coarsely reticulate over a large area; pubescence consisting of inconspicuous, sparse, fine hair of medium length, and a more conspicuous, ventrally directed epistomal brush.

Pronotum 0.84 times as long as wide; anterior margin rather broadly rounded, bearing from four to eight marginal teeth that decrease in size laterally; summit on basal third; asperate in front of summit, asperities rather abundant, large, usually narrow, rarely arranged in one or more subconcentric rows near summit; posterior and lateral areas closely, rather finely, deeply granulate-punctate; more granulate basally, particularly in posterolateral angles; pubescence consisting of rather short, fine, recumbent hair, coarse on asperate area.

Elytra shining; striae usually not impressed, punctures distinctly impressed, rather fine, separated by a distance greater than their own diameters; interstriae two to three times as wide as striae, punctures fine, abundant, confused. Declivity rather steep, convex, strial and interstrial punctures obsolete. Elytral vestiture consisting of uniseriate rows of short, hairlike, strial setae; abundant, confused, short, interstrial, scalelike setae; and uniseriate rows of widely spaced, rather long, slender, interstrial bristles on disc, each bristle distinctly longer than distance between rows of bristles.

Male.-Similar to female, elytral scales usually slightly larger.

Distribution.-Alaska, California and Nuevo León to Newfoundland and New York.

Alaska: Chatley River (E Central), Kenai Peninsula. CANADA: Alberta: Banff, Lake Louise. British Columbia: Bowser, Hope Mountain, London Hill Mine near Bear Lake, Mt. Apex Hedley, Nicomin Ridge, Pine Pass, Rogers Pass, Stanley. Manitoba: Churchill. New Brunswick: Fredricton. Prince Edward Island: Riley Brook. Newfoundland: Cornerbrook. Pasadena. Nova Scotia: Kejimkujik N.P. Ontario: Algonquin Park, Arnprior, Kaladar. Quebec: Gaspé. USA: Arizona: Jacob's Lake. California: Devil's Post Pile N.M. Colorado: Cameron Pass, Colorado N.F., Norwood, Ridgeway. Idaho: Sandpoint. Maine: Orono. Montana: Glacier N.P. New Mexico: Sandia Mts. New York: Cranberry Lake, Seneca Lake. Oregon: Corvallis, Elk Lake. Utah: Alta, Beaver, Kamas, Logan Canyon, Mirror Lake in Summit Co., Mt. Nebo, Wolf Creek Pass. Washington: Metaline Falls. Mt. Rainier, Naches R.S. MEXICO: Nuevo León: Cerro Potosí.

Hosts.-Abies concolor, A. grandis, A. magnifica, A. lasiocarpa, A. sp., Picea engelmannii, P. glauca, and P. rubens.

Biology.-As described for the genus. This species has been taken in suppressed trees and in shaded out and broken branches. In emerging reared material copulation occurred on the outer surface of the bark of the brood tree before flight. This may or may not be normal behavior for the species.

Notes. - The above treatment was based on the holotypes of ruficollis, approximatus, grandis, amabilis, canadensis, mainensis, and coloradensis, and on 305 other specimens.

This form probably intergrades completely with fraseri. Separate subspecies are maintained only because insufficient material is available for a proper evaluation. Specimens from Utah and North Carolina differ conspicuously, but these characters are not consistent throughout the range of this species.

## Genus HypOCRyphaluS Hopkins

Hypocryphalus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:4 I (Type-species: Hypocryphalus rotundus Hopkins, original designation)
Dacryphalus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:42 (Type-species: Dacryphalus obesus Hopkins, original designation); Schedl, 1938, Trans. Roy. Soc. So. Australia 62:48. Synonymy
Diagnosis.- This genus is distinguished from Cryphalus Erichson by the 5 -segmented antennal funicle, by the procurved sutures on
the antennal club, and by the cylindrical third tarsal segments.

Description.- Length $1.6-1.9 \mathrm{~mm}, 2.2$ times as long as wide; color light brown; sexes similar. Frons broadly convex, conservatively sculptured. Eye emarginate, finely granulate. Antennal funicle 5 -segmented; club large, subcircular, with three procurved sutures marked only by rows of setae. Pronotum and elytra as in Cryphalus. Third tarsal segments cylindrical.

Distribution.- Florida and Mexico to Brazil, SE Asia to Australia and Africa; more than 30 species are known in the Old World, one of which was introduced into North and South America in mango trees.

Brology.- Species in this genus are monogamous and phloeophagous, with habits essentially as in Cryphalus.

## Hypocryphalus mangiferae (Stebbing)

Figs. 192-194
Cryphalus inops Eichhoff, 1872. Berliner Ent. Zeitschr. 15:131 (Holotype. female; Guadeloupe; Brussels Mus.). Appeal to suppress pending
Hypothenemus griseus Blackburn. 1885, Trans. Roy. Soc. Dublin (2)3:194 (Holotype, female; plains of Ilonolulu, Oahu, Hawaiian Islands; British Mus. Nat. Hist.). Appeal to suppress pending
Hypothenemus sp.(?) Stebbing, 1903, Indian Mus. Notes 6(1):68
Cryphalus mangiferae Stebbing, 1914, Indian Forest Insects, p. 542 (Lectotype, female; Eastern Dun, India, British Mus. Nat. Hist., present designation.)
Hypocryphalus mangiferae: Beeson, 1929. Insects of Samoa 4:226; Wood, 1954. Univ. Kansas Sci. Bull. 36(2):999.
Hypocryphalus mangiferae Eggers, 1928 (nec Stebbing, 1914), Inst. Biol. (Sao Paulo) Arquivos 1:85 (Lectotype, male; Brazil; U.S. Nat. Mus., 60177, designated by Anderson and Anderson, 1971, Smithsonian Contrib. Biol. 94:19); Eggers, 1931, Wiener Ent. Zeit. 47:185. Synonymy
Diagnosis.- Because of the host, distribution, and generic characters, this species is not likely to be confused with any American species.

Female.- Length $1.6-1.9 \mathrm{~mm}$, about 2.2 times as long as wide, body color dark yellowish brown.

Frons broad, convex above, more or less flattened below; surface finely aciculate, reticulate above frons; evidently punctured only at sides and above; pubescence consisting of very fine, inconspicuous hair of medium length, a more conspicuous, short, ventrally
directed brush on epistomal margin. Eye narrowly, rather deeply emarginate; finely granulate. Antennal club large, subcircular, slightly longer than scape; not septate, with three procurved sutures indicated by rows of setae.

Pronotum about 0.93 times as long as wide; anterior margin armed by four (rarely three or five) teeth of moderate size, median pair slightly larger, closely placed, lateral ones separated by a distance at least equal to the basal width of one tooth; summit rather indefinite, near middle; asperate in front of summit, asperate area closely, finely punctured; posterior and lateral areas uniformly, closely, finely granulate; pubescence consisting of abundant, rather short, fine, recumbent hair, and a few longer erect bristles.

Elytra dull, not shining; striae impressed, punctures obscure, not impressed; interstriae two to three times as wide as striae, covered with closely placed, minute, confused granules, intermixed with a few minute, shallow punctures; each granule bearing a seta. Declivity convex, not steep. Elytral vestiture consisting of abundant, short, coarse, recumbent interstrial and strial hair; and uniseriate rows of long, slender, hairlike interstrial bristles.

Male.- Similar to female except posterior margin of abdominal sternum 5 more broadly rounded.

Distribution.- Circumtropical; it occurs wherever the host is cultivated.

USA: Florida: Homestead, 22-V-51, mango. S. L. Wood. MEXICO: Veracruz: Dos Amates, 5-V-69, D. E. Bright. HONDURAS: La Ceiba, 20-V-15, 17-VI, 26-VIII49, at light, E. C. Becker. COSTA RICA: Limón, 26-VIII-63, mango, S. L. Wood. PANAMA: Summit Gardens, Canal Zone, 2I-VII-66, mango, S. L. Wood.

OTHER AMERICAN COUNTRIES: Barbados, Brazil, Hawaii, Venezuela.

Host.- Mangifera indica.
Biology.- Apparently as in Cryphalus, except that the parental egg chamber is much more irregular. The monogamous phloeophagous beetles infest unthrifty branches on living trees as well as recently cut, larger material.

Notes. - The above treatment was based on the holotypes of inops and griseus, on the lectotype of mangiferae Eggers, and on 166 other specimens.

## Genus TRISCHIDIAS Hopkins

Trischidias Hopkins, 1915, U.S. Dept. Agric. Rept. 99:I2 (Type-species: Trischidias georgiae Hopkins, original designation)
Diagnosis.- This genus is distinguished from Hypothenemus by the entire eye, by the 3 -segmented antennal funicle, by the aseptate sutures of the antennal club, by the very small size, and by the stout body form.

Description.- Length, female 0.65-1.10 mm , male 60 percent as large as female, 2.0-2.3 times as long as wide; males dwarfed in size, with abnormal sculpture; probably partly parthenogenetic. Frons broadly convex, conservatively sculptured. Eye finely granulate, entire; reduced in male to onethird size of female. Antennal funicle 3 -segmented, sometimes with a partial fourth segment largely or totally fused to club. Pronotum with basal and posterior third of lateral margins with a fine, raised line; asperate in front of summit; anterior margin armed by two to four teeth. Elytra striate, punctures rather coarse; sculpture conservative; vestiture of hairlike and scalelike setae.

## Key to the Species of Trischidias

1. Body 2.3 times as long as wide; anterior margin of pronotum normally with four teeth; elytral striae less coarsely punctured; interstriae wider than striae; body and scale color lighter; Kansas and Maryland to Louisiana and Florida; female $0.65-0.80 \mathrm{~mm}$
l. atoma (Hopkins)

- Body stouter, 2.0 times as long as wide; anterior margin of pronotum normally with two teeth; elytral striae more coarsely punctured; interstriae narrower than striae, body and scale color darker
2(1). Strial punctures not increasing in size posteriorly; declivital interstriae about as wide as on disc, strial punctures about as large as on disc; Florida: Rhizophora; female $0.65-0.80 \mathrm{~mm}$

2. minutisima Wood

- Strial punctures increasing conspicuously in size posteriorly; declivital interstriae less than one-half as wide as striae, strial punctures larger than on disc; Georgia; female 1.1 mm $\qquad$ 3. georgiae Hopkins

## 1. Trischidias atoma (Hopkins)

 Fig. 194Hypothenemus atomus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:15 (Holotype, female, Morgantown, West Virginia; U.S. Nat. Mus., 7565
Trischidias atoma: Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1068
Hypothenemus impressifrons Hopkins, 1915, U.S. Dept. Agric. Rept. 99:15 (Holotype, female; Morgantown. West Virginia: U.S. Nat. Mus., 7355): Wood, 1954, Univ. Kansas Sci. Bull. 36(2):106s. Synonymy
Hypothenemus marylandicae Hopkins, 1915, U.S. Dept. Agric. Rept. 99:15 (Holotype, female; Pregnall, South Carolina; U.S. Nat. Mus., 7522): Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1068. Synonymy
Hypothenemus rohiniae Hopkins, 1915, U.S. Dept. Agric. Rept. 99:15 (Holotype, female: Chevy Chase, Maryland; U.S. Nat. Mus., 7523): Wood, 1954, Univ. Kansas Sci. Bull. 36(2):106s. Synomymy
Hypothenemus toxicodendri Hopkins, 1915, U.S. Dept. Agric. Rept. 99:15 (Holotype, female; Morgantown, West Virginia; U.S. Nat. Mus., 7356); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1068. Synomymy
Diagnosis.- This species is distinguished from minutissima Wood and georgiae Hopkins by the more slender body form, by the presence of four marginal teeth on the pronotum, by the less coarsely punctured striae, and by the lighter body and scale color.

Female.-Length $0.75-1.00 \mathrm{~mm}, 2.32$ times as long as wide, body color dark brown.

Frons convex, a weak transverse impression just above epistoma, a median impression of variable depth and length extending from upper level of eyes toward epistoma; surface coarsely reticulate and with a few minute, inconspicuous punctures; pubescence scarcely evident, consisting of a few fine hairs of medium length. Antennal club large, longer than scape, 1.28 times as long as wide, sutures straight.

Pronotum 0.91 times as long as wide; anterior margin slightly produced, with four subcontiguous teeth (rarely five or six), median pair distinctly larger; summit at middle; posterior and lateral areas coarsely reticulate, with a few scattered granules; hairlike
pubescence shorter and intermixed on posterior half with longer, equally abundant, scalelike setae.

Elytra shining: striae slightly impressed, punctures fine, distinct, rather shallow, separated by distances equal to their own diameters; interstriae wider than striae, punctures small, rather coarsely granulate, evenly spaced in uniseriate rows, each bearing an erect scalelike bristle. Declivity moderately steep, convex. Elytral vestiture consisting of minute, recumbent, hairlike, strial setae; and uniseriate rows of broad, erect, scalelike, interstrial bristles, each bristle on declivity one to one and one-half times as long as wide.

Male.- One male observed similar to female except length 0.53 mm , body stouter (damaged, could not measure); eye reduced in size, about one-half as large as in female; antennal funicle 3 -segmented, club smaller and more slender; pubescence slightly longer.

Distribution.- Kansas and Maryland to Louisiana and Florida.

USA: District of Columbia: Washington. Florida: Florida Keys, Sebring. Kansas: Lawrence. Louisiana: Covington. Maryland: Chevy Chase. Mississippi: Trimcane Swamp, Vicksburg. New Jersey: Westville. North Carolina: Cherokee, Tryon. South Carolina: Pregnall. Tennessee: Gatlinburg. West Virginia: Morgantown.

Hosts.-Acer rubrum, Asimina trilobata, Carya spp., Castanea dentata, Quercus marylandica, Rhizophora mangle, Rhododendron sp., Rhus toxicodendron, Robinia pseudoacacia, Salix nigra, S. sp., Ulmus americana.

Biology. - This species attacks the phloem of recently broken or unthrifty twigs and small branches. Only the females attack the new host where each constructs a small irregular cavity at or near the cambium. The irregular larval mines are rather short if they depart from the parental gallery. Males are rare, dwarfed, and flightless, and mate in the brood chambers before becoming fully sclerotized.

Notes.- The above treatment was based on the holotypes of atomus, impressifrons, marylandicae, robiniae, and toxicodendri, and on 45 other specimens.

## 2. Trischidias minutissima Wood

 Fig. 192, 194Trischidias minutissima Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1069 (Holotype, female; Sugar Loaf Key, Florida; Snow Ent. Mus., Univ. Kansas)
Diagnosis.- The stouter body form, presence of two (rarely four) marginal teeth on the pronotum, the more coarsely punctured elytral striae, narrower interstriae, and darker body and scale color distinguish the female of this species from that of atoma (Hopkins). It is more closely allied to georgiae Hopkins but differs by the smaller body size, by the strial punctures that do not increase conspicuously in size posteriorly, and by the subcontiguous marginal teeth on the pronotum.

Female. - Length $0.65-0.80 \mathrm{~mm}, 2.00$ times as long as wide, body color black, scales dusky.

Frons convex, a weak transverse impression just above epistoma; a narrow median impression of variable depth and length extending from above upper level of eyes toward epistoma; surface coarsely reticulate with a few minute, inconspicuous punctures; pubescence scarcely evident, consisting of a few fine hairs of medium length. Antennal club large, longer than scape, 1.18 times as long as wide, sutures straight.

Pronotum 0.82 times as long as wide; anterior margin slightly produced, with two subcontiguous teeth, rarely with an additional pair of small granules lateral to teeth; summit at middle; posterior and lateral areas coarsely reticulate, with a few scattered granules; hairlike pubescence shorter and intermixed on posterior half with longer, equally abundant scalelike setae.

Elytra shining; striae slightly impressed, punctures rather large, deep, separated by distances equal to their own diameters; interstriae distinctly narrower than striae, punctures small, evenly spaced in uniseriate rows, each coarsely granulate and bearing an erect scalelike bristle. Declivity moderately steep, convex. Elytral vestiture consisting of minute, recumbent hairlike strial setae; and uniseriate rows of dark, broad, erect, scalelike, interstrial bristles, each bristle on declivity one to one and one-half times as long as wide.

Distribution.-S Florida.

USA: Florida: Sugar Loaf Key, 3-VII-51, Rhizophora mangle, S. L. Wood.

Biology.- This minute species infested fungus pustules just under the outer bark of broken aerial roots of red mangrove.

Notes.- The above treatment was based on 10 paratypes and on one other specimen.

## 3. Trischidias georgiae Hopkins

Trischidias georgiae Hopkins, 1915, U.S. Dept. Agric. Rept. 99:12 (Holotype, female; Brunswick, Georgia; U.S. Nat. Mus., 7370)
Diagnosis.- This species differs from minutissima Wood by the larger size, by the strial punctures increasing in size toward declivity, and by the smaller, more widely spaced teeth on the anterior margin of the declivity.

Female.- Length 1.1 mm , about 2.0 times as long as wide, body color black.

Frons convex, a weak transverse impression just above epistoma, a short, shallow, median impression between eyes; surface rather coarsely reticulate, with a few minute, inconspicuous punctures; pubescence scarcely evident, consisting of a few fine hairs of medium length. Antennal club large, longer than scape.

Pronotum with anterior margin slightly produced, with two median teeth separated by basal width of one tooth; summit at middle; posterior and lateral areas coarsely reticulate, with a few scattered granules; hairlike pubescence shorter and intermixed on posterior half with longer, equally abundant, scalelike setae.

Elytra shining; striae slightly impressed, punctures rather large, deep, separated by distances equal to half their own diameters, becoming larger and closer toward declivity; interstriae distinctly narrower than striae, punctures small, rather coarsely granulate and evenly spaced in uniseriate rows, each bearing an erect scalelike bristle. Declivity moderately steep, convex; strial punctures very coarse, deep, separated by less than half their own diameters; interstriae narrow, about half as wide as striae. Elytral vestiture consisting of minute, recumbent, hairlike, strial setae; and uniseriate rows of rather dark colored, broad, erect, scalelike, interstrial bristles, each bristle on declivity one to one and one-half times as long as wide.

Distribution.-Georgia.
USA: Georgia: Brunswick, 3-111, H. G. Hubbard and E. A. Schwarz.

Notes. - The above treatment was based on the holotype.

## Genus HYPOTHENEMUS Westwood

> Hypothenemus Westwood, 1836, Trans. Ent. Soc. London 1:34 (Type-species: Hypothenemus eruditus Westwood, monobasic)
> Stephanoderes Eichhoff, 1872, Berliner Ent. Zeitschr. 15:132 (Type-species: Stephanoderes chapuisi Eichhoff = Crypturgus dissimilis Zimmermann, subsequent designation by Hopkins, 1914. Proc, U.S. Nat. Mus, 48:130); Browne, 1963, Ent. Ber. 23:53. Synonymy
> Homeocryphalus Lindemann, 1876, Bull. Soc. Imp. Nat. Moscou 51:168 (Type-species: Stephanoderes ehlcrsii Eichhoff, =Hypothenemus eruditus Westwood, monobasic); Fauvel, 1884, Rev. d'Ent. 3:315. Synonymy
> Adiaeretus Hagedorn, 1909, Deutsche Ent. Zeitschr. 1909:744 (Type-species: Adiaeretus spinosus Hagedorn =Stephanoderes elaphas Eichhoff, monobasic); Schedl, 1939, Rev. Zool. Bot. Afr. 32:380. Synonymy

Diagnosis.- This genus is distinguished from other American Cryphalini by the emarginate eye, by the 3 - to 5 -segmented antennal funicle, by the antennal club with suture 1 almost straight and partly septate, suture 2 slightly procurved and marked by setae, by the fine, raised line on the basal and posterolateral margins of the pronotum, by the rather abundant vestiture, and by the dwarfed, often deformed, flightless males.

Description.- Length, females 0.9-2.2 mm , males rare $0.6-1.8 \mathrm{~mm}$, females 2.1-2.7 times as long as wide, males slightly stouter; color pale yellowish brown to black.

Frons variously sculptured. Eye elongateoval, emarginate; finely granulate. Antennal scape elongate, simple; funicle usually 5 -segmented in larger females, often 4 -segmented in females of smaller species ( 3 -segmented in most birnanus), males usually with one fewer segments than in female; club moderately large, elongate-oval, usually constricted at partly septate suture 1 , less strongly constricted at suture 2, suture 2 usually marked by setae. Pronotum with basal third of lateral margins and basal margin marked by a fine, raised line; anterior margin armed by a series of teeth; anterior slope coarsely asperate; summit near middle, usually well developed. Scutellum well developed. Elytra weakly
striate; declivity convex, conservatively sculptured. Costal margins slightly elevated toward apex. Fore tibiae armed by a series of four to six small teeth, four on outer distal margin; hind tibiae with about four teeth on distal margin; tarsi cylindrical.

Distribution.- Worldwide in tropical and subtropical areas; 39 American species are recognized from Panama northward; several hundred species have been described from this and other parts of the world, but a majority of them have been placed in synonymy (Wood 1972, etc.).

Biology. - The species of this genus attack small, cut, broken, or unthrifty branches and twigs of trees, shrubs, lianas, vines, weeds, and other plant material. A few species may infest the fruiting bodies or seeds of a wide variety of plants. One species, hampei (Ferrari), is a major pest of coffee. Because most species are prolific and live in a wide variety of hosts in coastal regions, they are ideally suited for transportation through commerce. Evidently erectus (LeConte), biramus (Eichhoff), hampei, areccae (Hornung), africanus Hopkins, setosus (Eichhoff), javanus (Eggers), brumneus Hopkins, columbi Hopkins, and californicus Hopkins all reached America from origins in the eastern hemisphere, and apparently obscurus (Fabricius), crudiae Panzer, pulverulentus Eichhoff, pubescens Hopkins, and eruditus Westwood have been exported from America to other parts of the world.

Mating, if it occurs in these partly parthenogenetic beetles, is among siblings in the brood host, or between mother and son. The males are dwarfed and flightless. Adult females locate a new host and construct tunnels in either the phloem, pith, or woody tissues. The eggs usually are deposited in a branch of the gallery. The period of incubation and larval development is short, perhaps as little as two weeks for the combined total in some tropical species. The larvae may extend the parental tunnel or they may feed individually or in groups. Evidently, when circumstances are favorable, more than one generation can be completed in the same piece of host material. Few offspring are produced by each female, usually fewer than a dozen, rarely more than 30 , but their short life cycle and adaptability often contribute to high populations.

The species of Hypothenemus are usually associated with ecological disturbances in or
adjacent to agricultural areas. They are uncommon in a virgin forest.

## Key to the Species of Hypothenemus

1. Frons convex, with or without a narrow median groove; usually devoid of a median frontal tubercle but, if present, elytral vestiture limited to rows of erect, uniseriate, interstrial scales and (usually) uniseriate rows of strial hair; interstrial ground vestiture absent (except in sundaensis)2

- Frons with a conspicuous tubercle or transverse carina at middle, lower half of frons weakly to strongly, concavely impressed; interstrial ground vestiture hairlike, rather abundant

2(1). Anterior margin of pronotum armed by two to four teeth; anterior slope of pronotum armed by $8-25$ coarse asperities; short ground vestiture on declivital interstriae scalelike (except hairlike in sundaensis), either hair- or scalelike on disc; mostly larger species, females $1.5-2.2 \mathrm{~mm}$3

- Anterior margin of pronotum armed by four to eight teeth; anterior slope of pronotum armed by 25 or more asperities; short interstrial ground vestiture either absent or hairlike; mostly smaller species, females $1.0-1.6 \mathrm{~mm}$, rarely 1.7 mm 10

3(2). Erect interstrial setae slender, each pointed at its apex; pronotal dise devoid of scalelike setae; anterior margin of pronotum armed by two subcontiguous teeth; ground vestiture on declivity slender, often as very coarse hair4

- Erect interstrial setae scalelike, uniseriate, each broadly rounded or truncate at its apex; pronotal dise with hair- and scalelike setae intermixed; anterior margin of pronotum armed by either two or four teeth6

4(3). Elytral ground cover on disc confused, rather abundant; longest interstrial setae on disc as long as distance between rows; Belize (British Honduras) to Jamaica and Venezuela, Java; 1.5-1.6 mm 1. sundaensis (Eggers)

- Short hair on dise in sparse strial rows; interstrial setae shorter than distance between rows; larger species5

5(4). Elytral declivity broadly convex, interstriae 3 weakly elevated; strial punctures on declivity as large as those on disc; declivital bristles much coarser and longer than on disc; pronotal disc longitudinally substrigose; Florida Keys; 1.7-1.9 mm
2. hirsutus (Wood)

- Elytral declivity more narrowly convex, interstriae 3 not elevated; strial punctures on declivity slightly smaller than on disc; interstrial bristles on declivity as slender as on dise and little if any longer; pronotal disc punctured, not at all strigose; Minnesota and Connecticut to Texas and N Florida; 1.6-2.4 mm

3. dissimilis (Zimmermann)

6(3). Anterior margin of pronotum armed by two (four in apicalis) teeth; anterior slope of pronotum armed by $8-12$ asperities; discal striae usually more distinctly impressed, punctures larger

- Anterior margin of pronotum armed by four teeth, lateral pair smaller; anterior slope of pronotum armed by at least 15 asperities; discal striae usually more feebly impressed, punctures averaging smaller

7(6). Interstriae 9 on apical half of declivity rather strongly elevated, elevation almost as high as wide; setae on apical elevation much more numerous; erect interstrial scales almost as long as distance between rows, spaced by similar distances within a row; Colima to Oaxaca; $1.7-2.0 \mathrm{~mm}$
4. apicalis Wood

- Declivital interstriae 9 equal in convexity to other interstriae, apical setae not more abundant; erect interstrial scales on declivity shorter and/or more slender; smaller species

8(7). Erect interstrial scales on declivity slender, each six to eight times as long as wide, spaced within a row by distances slightly greater than length of a scale; elytral surface very finely rugose; Nayarit to Oaxaca; females $1.4-1.7 \mathrm{~mm}$
5. indigens Wood

- Erect interstrial scales on declivity each about two to four times as long as wide, spaced within a row by distances slightly less than length of a scale; elytral surface almost smooth; Kansas and New York to Florida, Texas and Oаxaca; females $1.5-1.7 \mathrm{~mm}$

6. rotundicollis (Eichhoff)

9(6). Mature color black; erect interstrial scales on declivity more slender, each four to six times as long as wide; interstrial punctures on disc averaging larger, more strongly confused; antennal funicle always 5 -segmented; Texas to Honduras and Venezuela, Africa; female 1.7-2.2 mm 7. erectus Leconte

- Mature color reddish brown; erect interstrial scales on declivity stouter, about two to four times as long as wide; interstrial punctures on disc smaller, less strongly confused; antennal funicle commonly 3 -segmented; Florida to Panama; Hawaii to S Asia; female $1.5-2.1 \mathrm{~mm}$

8. birmanus (Eichhoff)
$10(2)$. Interstrial ground vestiture absent, elytral vestiture consisting only of uniseriate rows of erect interstrial scales and rows of fine strial hair, one hair arising from each puncture; antemal funicle usually 5 -segmented; mostly larger species, females $1.2-1.9 \mathrm{~mm}$

- Interstrial ground vestiture consisting of fine, confused hair, at least in posterolateral areas, in addition to uniseriate rows of erect scales and strial hair; antennal funicle usually 4 -segmented; smaller species, females $1.0-1.4 \mathrm{~mm}$ 22
11(10). Interstrial bristles on declivity very slender, flattened little if any, each bristle more than eight times as long as wide; anterior margin of pronotum armed by four teeth, rarely six12
- Interstrial bristles rather strongly flattened, each scale not more than six times as long as wide; anterior margin of pronotum usually armed by six or more teeth (four in squamosus and solocis)
12(11). Interstrial punctures on discal interstriae 2 and 3 rather strongly confused, each puncture bearing an erect, flattened bristle; Veracruz to Colombia and Venezuela; female $1.5-1.8 \mathrm{~mm}$

9. trivialis Wood

- Interstrial punctures on disc uniseriate; smaller species 13

13(12). Discal interstrial bristles rather strongly flattened, much wider than those on declivity; elytral declivity steep, confined to posterior fourth; interstrial punctures finely granulate on basal half of disc; Connecticut and Kansas to Panama and Cuba; female $1.5-1.7 \mathrm{~mm}$
10. interstitialis (Hopkins)

- Discal and declivital interstrial bristles equal in width; elytral declivity gradual, extending almost to middle of elytra; interstrial punctures on basal half of dise not at all granulate; Guatemala, Honduras, Brazil, Africa, SE Asia, etc.; coffee beans; female $1.4-1.6 \mathrm{~mm}$

14(11). Summit of pronotum indefinite, very broadly convex; pronotal asperities small, very numerous particularly around summit, exceeding 50 in number; tropical species

- Summit of pronotum narrowly, strongly convex, usually with a definite transverse impression on its posterior limits; pronotal asperities rather coarse, rarely exceeding 30 in number

15(14). Setae on pronotal dise all hairlike; asperities on pronotal summit higher, not associated with pitlike depressions; posterolateral areas of pronotum rather coarsely, deeply punctured, surface subreticulate, shining; Veracruz to Costa Rica; $1.6-1.7 \mathrm{~mm}$
12. dolosus Wood

- Vestiture on pronotal disc of scales and hair intermixed; asperities on pronotal summit smaller, each with a small circular pit on its posterior margin, white frass packed in these pits usually appearing as recumbent, subcircular scales; posterolateral areas of pronotum strongly reticulate, dull, punctures very small, shallow, obscure; Costa Rica to Colombia and Venezuela; 1.4-1.9 mm 13. opacus (Eichhoff)

16(14). Declivital striae rather strongly impressed, interstriae narrower than striae, rather narrowly convex and uniseriately armed by small, pointed denticles

- Declivital interstriae weakly if at all impressed, interstriae as wide or wider than striae; interstrial granules on declivity small, rounded if present18

17(16). Elytral declivity broadly convex; costal margin at apex of elytral declivity normal; declivital interstrial granules small, equally developed to apices of all interstriae; Florida and Cuba to Veracruz and Colima; female 1.3-1.5 mm

## 14. squamosus (Hopkins)

- Elytral declivity more narrowly convex, with costal margin near apex rather strongly elevated; interstrial tubercles on declivity larger except suppressed near apices of even-numbered interstriae; Sinaloa to Colima; female 1.3-1.5 mm

15. solocis Wood

18(16). Frons with a small, rounded median tubercle at upper level of eyes; lower half of frons shallowly impressed, longitudinally concave, with a variable, shallow, median groove ending dorsad in median tubercle; New Jersey and Texas to Argentina, etc.; female $1.4-1.6 \mathrm{~mm}$
16. crudiae (Panzer)

- Frons almost uniformly convex, devoid of a median tubercle

19(18). Entire elytral surface minutely rugose, including inner surface of strial punctures; frons with a rather deep, narrow median groove extending from upper level of eyes to epistoma; Florida and Costa Rica to Brazil, etc.; in twigs, seeds, and nuts; female $1.2-1.4 \mathrm{~mm}$
17. obscurus (Fabricius)

- Elytral surface largely smooth, shining; frontal groove, when present, much shorter, rarely occupying more than half distance from upper level of eyes to epistoma

20(19). Larger species; strial punctures very small, shallow, about half as wide as interstriae; Tamaulipas to Colombia; $1.6-1.8 \mathrm{~mm}$ 18. multidentatus (Hopkins)

- $\quad$ Smaller species; strial punctures larger, deeper, about as wide as interstriae ........... 21
$21(20)$. Punctures in lateral areas of pronotal dise not at all granulate; interstrial scales on declivity three to six times as long as wide; anterior margin of pronotum usually armed by six teeth; West Virginia and Texas to Brazil, etc.; 1.4-1.6 mm

|  | unctures in lateral areas of pronotal disc finely granulate; interstrial scales on eclivity about twice as long as wide; anterior margin of pronotum armed by our teeth; Texas to Tamaulipas; 1.1-1.3 mm $\qquad$ 20. sparsus Hop |
| :---: | :---: |
| 22 | Anterior margin of pronotum rather broadly rounded, usually bearing six teeth; mostly larger than 1.1 mm $\qquad$ 23 |
|  | Anterior margin of pronotum narrowly produced, armed by four or fewer teeth, with lateral pair reduced in size; smaller than 1.1 mm . $\qquad$ 29 |
| 23 | Posterolateral areas of pronotum rather deeply, coarsely, closely punctured to lateral margin $\qquad$ |
|  | Posterolateral areas of pronotum indistinctly, shallowly, finely punctured, punctures usually obsolete near lateral margin |
| 24 | Body slender, 2.5 times as long as wide; pronotum as long or longer than wide; pronotum rather broadly rounded in front: Maryland and S California to Florida and Michoacán; $1.0-1.4 \mathrm{~mm}$ $\qquad$ 21. californicus Hopk |
|  | Body stout, 2.2 times as long as wide; pronotum distinctly wider than long; pronotum narrowly rounded in front; tropical species |
| 4). | Posterolateral areas of pronotum smooth, shining, punctures not granulate; striae not impressed, punctures small, shallow; interstriae flat, smooth, devoid of granules; Chiapas; female 1.0 mm ............................................... 22. vesculus Wo |
|  | Posterolateral areas of pronotum finely, densely granulate; striae distinctly impressed, punctures rather coarse, deep; interstriae convex, uniseriately, rather coarsely granulate; Costa Rica to Panama; 1.2-1.3 mm ................... 23. ascitus Wo |
| 26(23) | Body small, stout, less than 2.4 times as long as wide; interstrial scales on declivity short, broad, each scale half as long as distance between rows, less than twice as long as wide; mature color yellowish brown |
| - | Body slender, more than 2.4 times as long as wide; interstrial scales on declivity equal in length to distance between rows, each more than three times as long as wide (occasional exceptions in eruditus); mature color dark brown to black $\qquad$ |
| 27(26). | Body stouter, 2.1 times as long as wide; antennal club larger, its width greater than width of eye; anterior margin of pronotum and posterior margin of elytra more narrowly rounded; strial punctures deeper, interstrial granules larger; Costa Rica; female 1.0 mm $\qquad$ 24. nanellus Wood |
| - | ody moderately stout, 2.3 times as long as wide; antennal club smaller, its idth less than width of eye; anterior margin of pronotum and posterior marin of elytra more broadly rounded; Florida, Texas, Durango, Yucatan, Hawaii; fruiting stalks of grass; female $1.0-1.1 \mathrm{~mm}$ $\qquad$ 25. pubescens Hop |

28(26). Anterior margin of pronotum rather narrowly rounded, median pair of teeth subcontiguous or very narrowly separated; declivital interstrial scales two to eight times as long as wide; S California, Texas, and New Jersey to Argentina, etc.; $1.0-1.3 \mathrm{~mm}$
26. eruditus Westwood

- Anterior margin of pronotum very broadly rounded, median pair of teeth very widely separated, other teeth widely spaced; declivital interstrial scales six to ten times as long as wide; Florida, Cuba, Hidalgo; female 1.2-1.4 mm

27. gossypii Hopkins

29(22). Anterior margin of pronotum bearing four teeth, median pair larger; strial punctures larger, more deeply impressed; declivital interstrial scales about three times as long as wide; Missouri; female 0.9 mm
28. distinctus Wood

- Anterior margin of pronotum narrowly produced into a slender, hornlike, median process; strial punctures small, obscure; declivital interstrial scales about twice as long as wide; Georgia to Florida; female $1.05-1.15 \mathrm{~mm}$

29. miles (LeConte)

30(1). Frontal tubercle or carina very short, impression below tubercle rather poorly
developed, tubercle and impression occupying less than median third of frons ....... 31

- Frontal carina weakly to strongly elevated, impression stronger, much wider, occupying at least median two-thirds 34

31(30). Rows of erect interstrial scales on basal half of elytra only, all vestiture near and on declivity of very short hair; Costa Rica to Venezuela; female 1.0-1.2 mm
30. teretis Wood

- Rows of erect interstrial scales on both disc and declivity ......................................... 32

32(31). Frons bearing a small but conspicuous flattened tubercle at upper level of eyes, impression below tubercle feebly if at all indicated; erect interstrial scales on declivity two to three times as long as wide; Tamaulipas, Colima, Hawaii; female $1.0-1.1 \mathrm{~mm}$
31. parallelus (Hopkins)

- Frontal tubercle less well developed, with a distinct, rather shallow impression on median third between upper level of eyes and epistoma (rather variable in both species)

33(32). Interstrial scales on declivity stouter, each three to four times as long as wide; Veracruz to Colombia and Venezuela; 1.1-1.3 mm 32. cylindricus (Hopkins)

- Interstrial scales on declivity slender, each about eight times as long as wide; Nayarit to Panama and Venezuela; 1.1-1.3 mm

33. suspectus Wood

34(30). Smaller, females $1.0-1.4 \mathrm{~mm}$, more slender, 2.4-2.5 times as long as wide; interstriae usually only slightly wider than striae; interstrial hairlike ground vestiture more abundant, proportionately longer

- Larger, females $1.3-1.8 \mathrm{~mm}$; stouter, 2.3 times as long as wide; interstriae usually more than twice as wide as striae; interstrial hairlike ground vestiture less abundant, proportionately shorter 36

35(34). Interstrial scales on declivity longer, more slender, each scale six or more times as long as wide; frontal carina poorly developed, lowr frons flattened, more strongly impressed; posterior half of pronotum more nearly shining, smoother;

- Interstrial scales on declivity shorter, broad, two to four times as long as wide; frontal carina more strongly, acutely elevated medially, lower frons more nearly concave; posterior half of pronotum mostly reticulate, less brightly shining; Florida, Texas, and Nayarit to Colombia and Venezuela; female 1.0-1.2 mm

35. columbi Hopkins

36(34). Interstrial scales on declivity almost as long as distance between rows, each scale broad, about two to three times as long as wide; pronotal surface in posterolateral areas smooth, shining, punctures rather abundant, moderately small, rather deep; Alabama, Louisiana, circumtropical; 1.7-1.9 mm
36. africanus (Hopkins)

- Interstrial scales on declivity more slender, at least four times as long as wide; posterolateral areas of pronotum reticulate to rugose-reticulate, punctures fine, shallow, less numerous, usually much less clearly defined

37(36). Body slender, 2.4 times as long as wide; anterior slope of pronotum with more than 25 small asperities; anterior margin of pronotum with six to eight serrations; Florida and Chiapas to Brazil, etc.; female 1.6-1.7 mm
37. setosus (Eichhoff)

Body stout, 2.2 times as long as wide; anterior slope of pronotum with 12-18
coarse asperities; anterior margin of pronotum armed by two to four serrations .... 38
38(37). Posterolateral areas of pronotum shallowly, finely punctured, punctures not at all granulate; interstrial scales on declivity slightly longer, each scale about equal in length to distance between rows, and more slender, about six to eight times as long as wide; transverse frontal carina less acutely elevated; Florida, Cuba, and Jalisco to Panama, Venezuela, etc.; female, $1.4-1.7 \mathrm{~mm}$
38. javanus (Eggers)

- Posterolateral areas of pronotum less closely punctured, most punctures finely granulate or feebly vulcanate; interstrial scales on declivity slightly shorter, each scale about two-thirds as long as distance between rows, stouter, ab out four times as long as wide; transverse frontal carina more acutely elevated; Florida, Texas, and Nayarit to Panama; 1.30-1.45 mm ......... 39. brunneus (Hopkins)

1. Hypothenemus sundaensis (Eggers)

Stephanoderes sundaensis Eggers, 1927, Treubia 9:396 (Holotype, female; Haboko, Sumatra: Eggers Coll., apparently on loan to Schedl)
Hypothenemus aequaliclatatus Schedt. 1939, Tijdschr. Ent. 82:33 (Syntypes; Buitenzorg, Java: Buitenzorg Museum and Schedl Coll.). Neu synonymy
Diagnosis.- This introduced species is distinguished from other American representatives of the genus having two teeth on the anterior margin of the pronotum by the rather abundant, confused, hairlike elytral ground vestiture, with the long hairlike setae closely set in rows.

Female.- Length 1.5-1.6 mm, 2.4 times as long as wide; color dark brown.

Frons convex, except shallowly impressed on median fourth just below upper level of eyes; surface below upper level of eyes coarsely, closely punctured; vestiture moderately abundant, of fine, long hair.

Pronotum essentially as in biramanus (Eichhoff) except anterior margin usually armed by only two contiguous teeth and posterior areas without reticulation.

Elytra 1.6 times as long as wide; sides straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, punctures minute, shallow; interstriae six or more times as wide as striae, almost smooth, punctures minute, much smaller than those of striae, some of those near base minutely granulate. Declivity convex,
steep; sculpture as on disc. Vestiture of short, confused, moderately abundant, hairlike, strial and interstrial setae, and interstrial rows of long hair, each three to four times as long as ground cover, their length about equal to distance between rows, spaced by less than half that distance within a row.

Distribution.- British Honduras, Jamaica, Venezuela, Indonesia.

BRITISH HONDURAS: " M -tee" District, 15-VI-(6G, Peck. JAMAICA: Bog Walk, 5-YIII-67, L. and C. W. O’Brien. VENEZUELA: Ocumare in Aragua.

Notes.- The above treatment was based on the holotype of sumdaensis, on 2 topotypic specimens of aequaliclavatus that were compared by Kalshoven to his syntypes, and on 13 other specimens.

## 2. Hypothenemus hirsutus (Wood)

Fig. 194
Stephanoderes hirsutus Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1020 (Holotype, female; Plantation Key. Florida: Snow Ent. Mus., Univ, Kansas)
Diagnosis.- This species is distinguished from dissimilis (Zimmermann) by the more broadly convex elytral declivity, with interstriae 3 more strongly convex, by the much longer, coarser, more abundant bristles on the elytral declivity, by the larger strial punctures, and by the larger, less abundant interstrial punctures.

Female.- Length $1.7-1.9 \mathrm{~mm}, 2.3$ times as long as wide; color almost black.

Frons evenly convex, finely aciculate; punctures of moderate size, depth, and density; vestiture inconspicuous.

Pronotum 0.88 times as long as wide; widest behind middle, sides strongly arcuate, converging on anterior half to rather broadly rounded anterior margin; anterior margin armed by two large, subcontiguous teeth; summit slightly behind middle, well developed; about 8-14 coarse asperities on anterior slope; posterior areas shining, obscurely, longitudinally strigose behind summit, punctures rather coarse, close, deep. Vestiture hairlike, moderately long.

Elytra 1.4 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae very feebly impressed, punctures moderately coarse, close, rather deep; interstriae slightly wider than striae, smooth, shining, punctures uniseriate, rather small. Declivity broadly convex, steep; interstriae 2 weakly impressed, 3 weakly convex. Vestiture on disc of uniseriate rows of fine, short, strial hair and rows of longer, erect, interstrial bristles; on declivity considerably longer, more abundant, coarser, each acutely tapered from base; scalelike setae entirely absent.

Male.- Similar to female except smaller, $1.3-1.5 \mathrm{~mm}, 2.0$ times as long as wide; eyes reduced in size, half as large as in female; antennal club more slender; anterior margin of pronotum usually devoid of teeth; elytral sculpture less distinct and more variable.

Distribution.- Florida Keys.
USA: Florida: Key Largo, 25-V1-51, Ardesia paniculata and Lysiloma bahamensis, S. L. Wood; Matecumbe Key, 28-VI-51, Acras sapota, Eugenia buxifolia, and Pithecellobium unguis-cati, S. L. Wood; Plantation Key, 26-VI-5I, Ipomoea cathartica, S. L. Wood; Grassy Key, 27-VI-51, Reynosia septentrionis, S. L. Wood; Key Vaca, 29-VI-51, Pithecellobium guadelupense, S. L. Wood; Sugar Loaf Key, 3-V11-51, Metopium toxiferum, S. L. Wood; Big Pine Key, 7,8-III, E. A. Schwarz; Key West, 6-IV-03, E. A. Schwarz.

Hosts.-Acras sapota, Ardesia paniculata, Eugenia buxifolia, Ipomoea cathartica, Lysiloma bahamensis, Metopium toxiferum, Pithecellobium guadelupense, P. unguis-cati, Reynosia septentrionalis.

Bıology.- Essentially as in dissimilis.
Notes. - The above treatment was based on 50 paratypes.

## 3. Hypothenemus dissimilis (Zimmermann)

 Figs. 191-194Crypturgus dissimilis Zimmermann, 1868, Trans. Amer. Ent. Soc. 2:144 (Holotype, female; North Carolina: Mus. Comp. Zool.)
Hypothenemus dissimilis: LeConte, 1876, Proc. Amer. Philos. Soc. 15:356
Stephanoderes chapuisii Eichhoff, 1872, Berliner Ent. Zeitschr. 15:132 (Lectotype, female; America bor.: Brussels Mus., present designation); Eichhoff, 1896, Proc. U.S. Nat. Mus. I8:608, 610. Synonymy
Diagnosis.- This species is distinguished from hirsutus Wod as indicated in the above key and in the diagnosis of hirsutus.

Female.- Length $1.6-2.4 \mathrm{~mm}, 2.3$ times as long as wide; color dark brown to black.

Head essentially as in hirsutus. Pronotum as in hirsutus except anterior slope armed by

Fig. 193. Cryphalini spp., posterior face of protibia: 25. Procryphalus utahensis; 26, Trypophloeus ( $=$ Cryphalus of authors) populi; 27, Scolytogenes ( $=$ Cryphalomorphus) knabi; 28, Cryphalus (=Taenioglyptes) pubescens; 29, Hypocryphalus mangiferae; 30, Cryptocarenus heveae; 31, Hypothenemus dissimilis; 32, Hypothenemus eruditus. (After Wood 1954:1083.)

10-16 coarse asperities, posterior area less distinctly strigose.

Elytra as in hirsutus except strial punctures smaller, about half as wide as interstriae; interstrial punctures smaller, confused; declivity more narrowly convex, interstriae 2 not impressed, 3 not elevated; declivital vestiture of short, scalelike ground cover and longer, erect, coarse, pointed hair.

Male.-As in female except differing as in male and female hirsutus.

Distribution.- Minnesota and Connecticut to Texas and N Florida.

USA: Alabama: Mobile. Connecticut: Bradford, Hartford, New Haven. District of Columbia: Washington. Florida: Biscayne Bay, Dade City, Dunedin, Gainesville, Greenville, Jacksonville, La Belle, Monticello, Oleno St. Pk., Sanford, Sebring, Seminole, Snead, Suwanee Springs. Georgia: Bruswick, Waycross. Illinois: Lawrenceville. Indiana: Lawrence Co.. Posey Co.. Vermillion Co., Warren Co. Louisiana: Covington. Kentucky: Williamshurg. Maryland: College Park. Minnesota: Olmstead Co. Mississippi: Lucedale, Nicholson. Missouri: Warrensburg. New Jersey: "N.J." New York: Me!tille on Long Island, Pinelawn on Long Island, Yaphank. North Carolina: Aberdeen, Cherokee, Marston, Monroe, Southern Pines, Tryon. Ohio: Columbus, Franklin Co.. Hocking Co. Pennsylvania: Allegheny, Chambersburg, Easton, Jeanette, Mit. Alto, Philadelphia, Pittsburgh, Wind Gap. South Carolina: Awendaw, Edisto Island, Myrtle Beach. Tennessee: Gatlinburg. Texas: Columbus, Hidalgo Co., Lexington, College Station. West Virginia: Doddridge Co., Kanawha Co.. Morgantown.

Hosts.- Acer rubrum, Carya spp., Cercis canadensis, Fagus grandifolia, Kalmia latifolia, Quercus spp., Ocotea catesbyana, Rhamnus lanceolata, Vitis spp.

Biology.- The females attack recently injured or broken twigs and small branches, where they construct cavities in the pith and/or wood. From the central chamber one or more short, longitudinal egg galleries may extend with the grain of the wood. Eggs are deposited in the tumnels or in the central chamber. The larvae and young adults extend the parental tunnels, often consuming the entire pith.

Notes. - The above treatment was based on the holotype of dissimilis, on three syntypes of chapuisii, and on 98 other specimens. Three female syntypes of chapuisii in the Chapuis collection at the Institute Royal des Sciences Naturelles, Brussels, were examined; the first of these is here designated as the lectotype of Stephanoderes chapuisii Eichhoff.

## 4. Hypothenemus apicalis Wood

Hypothenemus apicalis Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):19 (Holotype, female; 3 km or 2 miles E Armeria, Colima, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from rotundicollis (Eichhoff) and erectus LeConte by the much more slender erect, interstrial bristles and by the strongly elevated interstriae 9 at the elytral apex.

Female.- Length $1.6-2.0 \mathrm{~mm}, 2.3$ times as long as wide; color dark brown, vestiture pale.

Frons essentially as in rotundicollis. Pronotum as in rotundicollis, with 10 to 14 asperities on anterior slope, posterior area more strongly reticulate, anterior margin armed by four teeth, lateral pair usually smaller.

Elytra as in rotundicollis except declivity not as steep, its outline with a distinct lateral constriction near middle; declivital striae more strongly impressed, punctures shallow, larger, interstriae 1-3 distinctly convex, 9 distinctly convex to junction with 3 then strongly elevated from there to apex. Vestiture of short, confused ground setae, almost hairlike on disc, becoming scalelike on declivity, and rows of erect interstrial bristles; each bristle longer on declivity, on declivity each as long as distance between rows or between bristles within a row, each about eight times as long as wide.

Distribution.- Colima to Oaxaca.
MEXICO: Colima: 3 km E Armeria, 28 -Vl- $65,70 \mathrm{~m}$, No. 1.30, liana. S. L. Wood. Oaxaca: 10 km SE Totolapan, 21-V1-67, 1000 m . No. 73, shrub, S. L. Wood.

Brology.- As in dissimilis.
Notes.- The above treatment was based on the type series of eight specimens.

## 5. Hypothenemus indigens Wood

Hypothenemus indigens Wood, 1974. Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):20 (Holotype, female; 9 km or 6 miles $S$ Huajuapan, Oaxaca, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from rotundicollis (Eichhoff) by the minutely granulose elytral surface and by the much more slender, more widely spaced, erect interstrial scales.

Female.-Length 1.4-1.7 mm, 2.4 times as long as wide; color dark brown.

Head and pronotum as in rotundicollis except pronotal asperities slightly smaller,
narrower, posterior areas more strongly reticulate.

Elytra 1.6 times as long as wide; as in rotundicollis except surface minutely granulate, bristle-bearing interstrial punctures on dise granulate, declivital ground vestiture more nearly scalelike, and erect interstrial bristles much more slender and more widely spaced within a row; each bristle about eight times as long as wide, spaced within a row by distances slightly greater than length of a bristle.

Male.- Similar to female except 1.2 mm long; eye reduced in size; antennal club more slender; most characters less sharply formed; vestiture longer.

Distribution.- Nayarit to Oaxaca.
MEXICO: Jalisco: Volcán Colima, 23-V1-65, 2500 m , No. 103, shrub. Nayarit: Volcán Ceboruco, 5-V-65, 1100 m, No. 189, Scrjania. Oaxaca: 13 km SE Cameron, 21 -VI-67, No. 76, shrub; 9 km S Huajuapan, 16-V1-67. No. 45, Seriania; 17 km N Huajuapan, 15-V1-67, No. 43, Psittacanthus. Puebla: 5 km S Matamoros, 14-V1-67, 2000 m , No. 33, Toxicodendron. All were taken by me.

Hosts.-Psittacanthus sp., Seriania sp., and Toxicodendron sp.

Brology. - Similar to dissimilis.
Notes.- The above treatment was based on the type series of 19 specimens.

## 6. Hypothenemus rotundicollis (Eichhoff) Fig. 194

Stephanoderes rotundicollis Eichhoff, 1878, Mém. Soc. Roy. Sci. Liége (2)8:45, 145 (Syntypes?, female; America septentrionalis; presumably lost with Hamburg Mlus.)
Stephanoderes sculpturatus Eichhoff, 1878, Mém. Soc. Roy. Sci. Liége (2)8:45, 146 (Syntypes?, female; Temnessee; presumably lost with Hamburg Mus.); Eichhoff, 1896, Proc. U.S. Nat Mus. 18:608, 610. Synonymy
Stephanoderes quercus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:32 (Holotype, female; Berkeley, West Virginia; U.S. Nat. Mus., 7550); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1024. Synonymy
Diagnosis.- This species is distinguished from related forms by the small number of pronotal asperities, by having only two teeth on the anterior margin of the pronotum, by the short, comparatively broad, erect, interstrial scalelike bristles, and by other characters summarized in the above key and in the diagnosis of related species.

Female.- Length $1.5-1.7 \mathrm{~mm}, 2.2$ times as long as wide; color dark brown.

Head and pronotum essentially as in dissimilis (Zimmermann) except anterior slope of pronotum armed by only 8-12 asperities, anterior margin armed by two teeth, posterior areas more finely, more shallowly punctured, with no indication of being strigose behind summit. Vestiture of fine hair, slender scales intermixed on posterior half.

Elytra 1.4 times as long as wide; essentially as in dissimilis except strial punctures on declivity slightly larger, interstrial punctures on dise finer. Vestiture with short ground cover hairlike on disc, stouter, almost scalelike on declivity, and with interstrial rows of erect scales, each erect scale on declivity two to four times as long as wide, scales two-thirds as long as distance between rows, spaced within a row by distances less than length of a scale.

Male.-Similar to female except length $1.3-1.4 \mathrm{~mm}, 2.0$ times as long as wide; differing from female as in hirsutus.

Distribution.- Kansas and New York to N Florida, Texas, and Oaxaca.

USA: Arkansas: Hot Springs. Florida: Snead. Georgia: Barnsville, Clarke Co. Kansas: Kiowa. Maryland: "Md." Missouri: Iron Mt., Warrensburg. New Jersey: Mt. Misery. New York: Peekskill. North Carolina: Monroe, Southern Pines, Tryon. Ohio: Hocking Co. Pemnsylvania: Angora, Franklin. Temnessee: Gatlinburg. Texas: Brownsville, Columbus, Dallas, Davis Mts., Devils River, Hidalgo Co., Lexington, Lopeno, Macdona, San Diego, Southmost, Victoria. West Virginia: Berkeley, Dellslow, Doddridge. MEXICO: Michoacán: Lombardia. Nayarit: 27 km E San Blas. Tamaulipas: Jimémez. Oaxaca: 83 km N Oaxaca. OTIIER AREAS: Puerto Rico.

Hosts.- Carya alba, Cercis canadensis, Fagus grandifolia, Mimosa sp., Quercus sp., Prosopis sp., Rhamnus lanceolata.

Biology.- As in dissimilis.
Notes.- The above treatment was based on the Hopkins series of rotundicollis, on the holotype of quercus, and on 36 other specimens. The unique holotype of rotundicollis is lost and the exact type locality is unknown; however, Eichhoff established the synonymy with sculpturatus, which came from Tennessee (types also lost), and he described the type as having two marginal teeth on the pronotum and rows of erect scales on the elytra. Only one species matching this description occurs in Tennessee. Schwarz received at least 99 numbered species of Scolytidae from Eichhoff, mostly syntypes. Of these, No. 60 was "Stephanoderes setosus";

Nos. 52-59 have not been found, but one of them could have included a specimen of sculpturatus. Hopkins also sent some of his material to Eichhoff for identification; unfortunately, the Eichhoff labels were removed from most of them and at present there is no indication of the authority who made the identification of his specimens.

## 7. Hypothenemus erectus LeConte Fis. 194

Hypothenemis erectus LeConte, 1876, Proc. Amer. Philos. Soc. 15:356 (Lectotype, female; Texas, by Belfrage presmably lower Rio Grande Valley; Mus. Comp. Zool., designated by Wood, 1972. Great Basin Nat. 32:45)
Hypothenemus calidus Blandford, 1904. Biol. Centr. Amer., Coleopt. 4(6):228 (Ilolotype, female. Motzorongo, Veracruz, Mexico; British Mus. Nat. Hist.): Wood, 1972, Great Basin Nat. 32:46. Symonymy
Stephanoderes puncticollis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:32 (Holotype, female: Tampico, Tamaulipas, Mexico; U.S. Nat. Mus., 7547); Wood. 1972. Great Basin Nat. 32:46. Synonymy
Stephanoderes cubensis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:32 (Holotype, female; Cayamas, Cuba; U.S. Nat. Mus., 755.3); Wood, 1972, Great Basin Nat. 32:46. Synonymy
Stephanoderes brunneicollis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:3.3 (Holotype, female; Round Mountain, Texas; U.S. Nat. Mus., 7356); Wood, 1954. Univ. Kansas Sci. Bull. 36(2):1026. Synonymy
Stephanoderes discedens Schedl, 1950, Bull. Inst. Roy: Sci. Nat. Belgique 26(50):23 (Holotype, female: St. Thomas: Schedl Coll.): Wood, I976, Great Basin Nat. 36:345. Synonymy
Diagnosis.- This species is distinguished from birmanus (Eichhoff) by the larger average size, by the darker body color, by the more slender erect, interstrial scales, by the smaller interstrial punctures, and by the consistently 5 -segmented antennal funicle.

Female. - Length $1.7-2.2 \mathrm{~mm}, 2.4$ times as long as wide; mature color black.

Head and pronotum as in dissimilis (Zimmermann) except anterior slope of pronotum armed by 15-20 coarse asperities, anterior margin armed by four teeth, lateral pair usually smaller, posterior areas irregularly reticulate, more finely punctured. Vestiture hairlike, with slender scales intermixed in posterior areas.

Elytra 1.4 times as long as wide; outline as in hirsutus; striae feebly if at all impressed,
punctures small, close, moderately deep; interstriae about three times as wide as striae, feebly convex, almost smooth, punctures fine, rather close, confused. Declivity convex, steep; essentially as on disc. Vestiture of short ground cover, hairlike on disc, stouter, almost scalelike on declivity, and rows of erect interstrial scales; each scale on declivity four to six times as long as wide, slightly shorter than distance between rows, spaced within a row by distance less than length of a scale.

Male.-Similar to female except 1.5-1.7 $\mathrm{mm}, 2.0$ times as long as wide; differing from female as in hirsutus.

Distribution.-S Texas and Cuba to Honduras, Venezuela, and Africa.
USA: Texas: Brownsville. Corpus Cristi, Davis Mts. Fuller, Hidalgo Co., Laguna, Montell, Round Mountain, San Diego, Southmost, Victoria. MEXICO: Chiapas: Ocosingo, Ocozocoautla. Colima: 3 km E Armeria, 24 km W Armeria, 6 km S Cihuatlán. Hidalgo: 25 km Nix miquilpan. Jalisco: 5 km S Atenquique. Volcán Colima. Nayarit: Los Corchos, 48 km N Tepic. 8 km S Rosamoradia, 45 km N Rosamorada. San Blas. Nuevo León: Chapinque. Monterrey. Puebla: 5 km S Matamoros. Queretaro: Landa de Matamoros. San Luis Potosi: El Salto. Sinaloa: Mazattán, Villa Union. Tamaulipas: Encinal, Tampico. Veracruz: Cerro Gordo, 12 km E Huatusco, 35 km SE Jalapa. Matías Romero. Motzorongo, Orizaba, Sontecampan. HONDURAS: Zamorano. VENEZUELA: Barrancas, Merida.

Hosts. - Condalia sp., Ficus sp., Inga sp., Miconia sp., Mimosa spp., Prosopis sp., Rubus sp., Seriania sp., Toxicondendron sp., Verbisina agricolorum, Vismia sp.

Brology.- As in idissimilis.
Notes.- The above treatment was based on the lectotype of erectus, on the holotypes of validus, puncticollis, cubensis, discedens, and brunneicollis, and on 223 other specimens. Because LeConte's species was based on two female syntypes bearing identical data, I here designate the one remaining syntype in the LeConte collection and bearing the type label as the lectotype of Hypothenemus erectus LeConte.

A cotype of Stephanoderes sambesianus Eggers, in the Eggers collection at the U.S. National Museum, appears to be conspecific with erectus; S. mozambiquensis Eggers (three cotypes) and S. dispar Eggers (one cotype) are doubtfully distinct. These specimens, the absence of closely related native species in America, and the distribution patterns in America, with little or no geographical variation, strongly suggest an African
origin of this species. Nevertheless, additional African material should be studied before Eggers's names are placed in synonymy.

## 8. Hypothenemus birmanus (Eichhoff)

Figs. 192, 194
Triarmocerus birmanus Eichhoff, 1878, Mém. Soc. Roy. Sci. Liége (2)8:486 (Syntypes?, female; Birma; presumably lost with Hamburg Mus.); Schedl 1942. Bishop Mus. Bull. 172:148 (Compared type to available specimen)
Stephanoderes birmanus: Wood, 1960, Insects of Mieronesia 18(1):35
Hypothenemus maculicollis Sharp. 1879. Trans. Roy Ent. Sox. London 77:101 (Syntypes; Oahu, Hawaiian Islands; British Mus. Nat. Hist.): Wood, 1972, Great Basin Nat. 32:43. Synonymy
Stephanoderes perkinsi Hopkins, 1915, U.S. Dept. Agric. Rept. 99:31 (Holotype, female; Honoluh. Hawaii; U.S. Nat. Mus., 7594): Wood, 1972, Great Basin Nat. 32:43. Stunonymy
Stephanoderes sterculiae Hopkins, 1915, U.S. Dept. Agric. Rept. 99:32 (Holotype, female; Calapan, Philippine Islands: U.S. Nat. Mus., 7551); Wood. 1972, Great Basin Nat. 32:43. Synonymy
Stephanoderes psidii Hopkins, 1915, U.S. Dept. Agric. Rept. 99:32 (Holotype, female: Calapan, Philippine 1slands; U.S. Nat. Mus., 7552); Wood. 1972. Great Basin Nat. 32:43. Synonymy
Stephanoderes alter Eggers, 1923, Zool. Meded. Roy. Mus. Nat. Hist. Leyden 7:219 (Syntypes, females New Guinea and Australia; Museo Civico Genova and U.S. Nat. Mus.); Wood, 1960, Insects of Micronesia 18(1):35. Synonymy
Stephanoderes pacificus Beeson. 1940. Bishop Mas Occas. Papers 15(18):197 (Holotype, female; Henderson Island; Bishop Mus.); Wood, 1960, Insects of Micronesia 18(1):35. Synonymy
Stephanoderes castancus Wood, 1954. Univ. Kansas Sci. Bull. 36:1027 (Holotype, female; Homestead. Florida; Snow Ent. Mus., Univ, Kansas): Wood, 1960, Insects of Micronesia 18(1):35. Synonymy
Diagnosis.- This species is distinguished from erectus (LeConte) by the smaller average size, by the reddish brown body color, by the stouter, erect interstrial scales, by the coarser interstrial punctures, and by the variable segmentation of the antennal funicle.

Female.- Length $1.5-2.1 \mathrm{~mm}$ (maximum American size 1.8 mm ), 2.3 times as long as wide; mature color reddish brown.

Head and pronotum as in crectus except antennal funicle variable, 3 - to 5 -segmented; pronotal asperities number 16-22, averaging smaller.

Elytra as in erectus except strial punctures larger, interstrial punctures larger and less numerous, tending to be uniseriate, and interstrial scales stouter and usually slightly
shorter and closer, each scale about two to four times as long as wide.

Male.-Similar to female except length $1.3-1.5 \mathrm{~mm}, 2.1$ times as long as wide, differing from female as indicated for hirsutus.

Distribution.-Florida to Panama, Hawaii to S Asia.

Fig. 194. Cryphalini spp., characters: 41. Cryphalus pubescens, male terga 7 and 8, 42, same, female tergum 7 (tergum 8 not visible); 43-84, anterior margin of pronotums: 4:3. Trypophloeus striatulus; 44, Trypophloeus salicis; 45. Trypophlocus populi; 46-47. Procryphalus utahensis: 48, Procryphalus mucronatus; 49, Scolytogenes knahi; 50-52, Cryphalus ruficollis ruficollis; 53. Hypocryphalus mangiferae; 54, Cryptocarenus heceac; 55. Cryptocaremus seriatus; 56, Hypothenemus hirsutus; 57. Hypothenemus dissimilis; 58, Hypothenemus rotundicollis: 59, Hypothenemus erectus; 60), Hypothenemus birmanas; 61, Hypothenemus jacanus; 62-63, Hypothcnemus brunncus variations; 64-65. Hypothenemus interstitialis variations: 67, Hypothenemus squamosus 66, 6S-72, Hypothenemus seriatus; 73-74, Hypoth enemus sparsus; 75-76, Hypothenemus califormicus: 77, Hypothenemus eruditus: 78, Hypothenemus puhescens: 79, Hypothenemus gossypii; 80, Hypothenemus columbi; 81, Hypothenemus distinctus; 82, Hypothenemus miles; 83. Trischidias atoma; 84, Trischidias minutissima. (After Wood 1954:1087.)

USA: Florida: Everglades N.P., Homestead, hey Largo, Miami, Perrine, Royal Palm Hammock St. Pk., Matheson Hammock in Dade Co. MEXICO: Colima: Isla Clarion. COSTA RICA: Playón. PANAMA: Canal Zone: Summit Gardens. OTHER AREAS: Burma, Celebes, Sri Lanka (Ceylon), Hawaii, India, Jamaica, Java, Malaya, Micronesia, New Guinea. Philippine Islands, Sarawak, Sumatra, Thailand.
Hosts.-Achras sapota, Adenanthera pavonia, Annona sp., Ardesia paniculata, Cassia florida, Dalbergia gastrophyllum, Eugenia buxifolia, Ficus aurea, Mangifcra indica, Ocotea catesbyona, Persea borbonia, Phelocarpus septrionalis, Quercus sp., Rhizophora mangle, Trema floridana, Vitis sp.
Bıology.- As in dissimilis.
Notes.- The above treatment was based on syntypes of alter and maculicollis, on the holotypes of perkinsi, sterculiae, psidii, pacificus, and castaneus, and on 191 other American specimens. The type of birmanus evidently is lost, but it was compared by Schedl (1942:148) to two specimens now in the Bishop Museum and found to differ only in size. Specimens from Java, Borneo, and Malaya vary considerably more in size than do those from America; specimens there commonly attain a length of 2.1 mm (the type was 2.0 $\mathrm{mm})$. The largest American specimens are 1.8 mm .
In some areas the antennal funicle is almost invariably 3 -segmented; in an adjacent area it may be consistently 5 -segmented. Occasional populations contain a mixture of 3 -, 4 -, and 5 -segmented structure, with some individuals exhibiting at least one incompletely divided segment.

## 9. Hypothenemus trivialis Wood

Hypothenemus tricialis Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):20) (Holotype, female; Santa Ana, San José, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from bolivianus Eggers by the smooth, shining elytral disc and smoother pronotal disc, by the more slender, slightly longer interstrial bristles, and by the much more strongly confused punctures and bristles on interstriae 2 and 3 on the basal half of the disc.

Female.- Length $1.5-1.8 \mathrm{~mm}, 2.2$ times as long as wide; color black.

Frons convex; a small, median impression at upper level of eyes; surface rather finely
rugose-reticulate, except smooth and shining in median area from epistoma to impression.

Pronotum 0.90 times as long as wide; widest on basal third, sides rather strongly, arcuately converging to rather narrowly rounded anterior margin; anterior margin armed by four teeth, lateral pair smaller; anterior slope armed by more than 35 moderately large asperities; posterior areas subreticulate, shining, granulate behind summit, granules sparse and intermixed with fine, shallow punctures laterally. Vestiture of hair, intermixed in posterior areas with slender scales.

Elytra 1.4 times as long as wide; outline as in related species; striae not impressed, punctures moderately large, shallow, their inner surfaces reticulate-granulate; interstriae smooth, shining, twice as wide as striae, punctures fine, uniseriate on 1 and 4-10, confused on 2 and 3 except near declivity. Declivity commencing near middle of elytra, rather gradual, convex; striae weakly impressed, punctures smaller, deeper; interstriae weakly convex, punctures uniseriate, finely granulate. Vestiture of rows of minute, fine, strial hair, and rows of erect interstrial bristles; each bristle slightly longer than distance between rows or between bristles within a row; each bristle on dise slightly flattened, usually not flattened on declivity.

Distribution. - Veracruz to Colombia and Venezuela.

MEXICO: Veracruz: Matías Romero. COSTA RICA: Beverley and Pandora in Limón, Cañas in Guanacaste, Finca Gromaco on Río Coto Brus and Rincon de Osa in Puntarenas, Río Damitas in the Dota Mts., and Santa Ana in San José. PANAMA: Canal Zone: Barro Colorado Island, Ft. Clayton. Paraíso, Summit. OTHER AREAS: Colombia, Venezuela.

Hosts.- Cuparia guatemalensis, Ochroma sp., Seriania sp., and Vismia guianensis.

Biology. - As in dissimilis.
Notes. - The above treatment was based on the type series of 53 specimens and on 17 other specimens. The elytral bristles in specimens from Mexico are distinctly shorter and broader than those from the southern areas.

## 10. Hypothenemus interstitialis (Hopkins) Fig. 194

[^16]Stephanoderes interpunctus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:28 (Holotype, female; Brownsville, Texas; U.S. Nat. Mus., 7378); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1033. Synonymy
Stephanoderes approximatus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:29 (Holotype, female; Columbus, Texas; U.S. Nat. Mus., 7381); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1033. Synonymy
Stephanoderes flavescens Hopkins, 1915, U.S. Dept. Agric. Rept. 99:29 (Holotype, female; Tallahassee, Florida; U.S. Nat. Mus., 7536); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1033. Synonymy
Stephanoderes obliquus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:30 (Holotype, female; Cayamas, Cuba; U.S. Nat. Mus., 7538); Wood, 1972, Great Basin Nat. 32:48. Synonymy
Stephanoderes opacipennis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:30 (Holotype, female; District of Columbia: U.S. Nat. Mus., 7540); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1033. Synonymy
Stephanoderes quadridentatus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:30 (Holotype, female; District of Columbia; U.S. Nat. Mus., 7383); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):103.3. Synonymy
Diagnosis. - This species is more likely to be confused with seriatus (Eichhoff) than with other American species, but it is distinguished by the stouter body, by the much more slender elytral scales and, usually, by the smaller number of teeth arming the anterior margin of the pronotum.

Female.- Length $1.5-1.7 \mathrm{~mm}, 2.3$ times as long as wide; body color dark brown to almost black, vestiture pale.

Head and pronotum essentially as in trivialis Wood except posterior area less granular, scales broader.

Elytra 1.4 times as long as wide; outline about as in hirsutus; striae not impressed, punctures moderately large, rather deep; interstriae almost smooth, as wide as striae, punctures uniseriate, fine, not granulate. Declivity limited to posterior third, steep, convex; striae feebly impressed; interstrial punctures indistinctly, finely granulate. Vestiture of rows of minute, obscure, fine strial hair, and rows of erect interstrial bristles; bristles slender, spaced within a row and between rows by distances slightly less than length of a declivital bristle, those on dise slightly shorter and more strongly flattened, less than six times as long as wide, those on declivity more than eight times as long as wide.

Male-Similar to female except 1.1-1.2 $\mathrm{mm}, 2.1$ times as long as wide; differing from female as in hirsutus.

## Distribution.- Connecticut and Kansas

 to Florida and Costa Rica.USA: Alabama: Mobile, Theodore. Connecticut: Brandford, Hamden. District of Columbia: "DC." Florida: Dade City, Dunedin, Gainesville, Jacksonville, La Belle, Monticello, Oleno St. Pk., Sanford, Sebring, Snead, Suwannee Springs. Georgia: Atlanta, Brunswick, Millner. Illinois: East St. Louis, Lawrenceville. Kansas: Laurence. Kentucky: Williamsburg. Louisiana: Baton Rouge, Boothville, Covington, Krotz Springs, New Orleans, St. Bernard. Maryland: Bladenburg, Plummer's Island. Mississippi: Corinth, Meridian, Nicholson, Trimcane Swamp, Vicksburg. New Jersey: Camden, Westville. North Carolina: Aberdeen, Black Mts., Cherokee, Monroe. Pennsylvania: Allegheny, Essington, Frankford, Philadelphia. South Carolina: Awendaw, Jacksonboro. Tennessee: Gatlinburg. Texas: Brownsville, Columbus, Dallas, Victoria. Virginia: Blacksburg, Cape Henry, Loudoun Co., Mt. Vernon. West Virginia: Morgantown. MEXICO: Chiapas: 21 km N Ocozoantla, 15 km SE Teopisca. Nayarit: Los Corchos, 48 km N Rosamorada. Veracruz: Cerro Gordo, 28 km E Coatzocoatcos, Cotaxtla, 14 km E Huatusco, 5 km W Jáltipan. guatemala: Volcán de Agua. honduras: Zamorano. COSTA RICA: San Isidro del General. Panama: Porto Bello. OTHER AREAS: Jamaica.

Hosts.- Acer rubrum, Aesculus sp., Carya spp., Cercis canadensis, Fagus grandifolia, Ficus sp., Liquidambar styracifla, Magnolia sp., Miconia sp., Mimosa sp., Morus rubra, Ocotea catesbyana, Persea borbonia, Picea sp., Prosopis sp., Quercus spp., Rhododendron sp., Rhus spp., Seriania sp., Vismia sp., Vitis spp.

Biology. - Essentially as in dissimilis.
Notes. - The above treatment was based on the holotypes of interstitialis, interpunctus, approximatus, flavescens, obliquus, opacipennis, and quadridentatus, and on 96 other specimens.

Variation throughout the range is slight except for the one specimen seen from Costa Rica. It is rather small and has the interstrial bristles slightly wider than those from elsewhere. An analysis of the significance of this variation must await the examination of additional specimens from the area south of Honduras.

## 11. Hypothenemus hampei (Ferrari)

Cryphalus hampei Ferrari, 1867, Die Forst.- und Baumzuchtschädlichen Borkenkäfer, p. 11, 12 (Syntypes, female; "Gallia," in coffee beans; apparently in Vienna Mus.)
Stephanoderes coffeae Hagedorn, 1910, Ent. Blätt. 6:1 (Syntypes, female: Entebbe, Uganda, Zentralafrika, Angola; British Mus.); Hagedorn, 1912, Ent. Blätt. 8:40. Synonymy

Xyleborus coffeivorus van der Weele, 1910, Teysmannia Batavia 21:308-316, also in Buitenzorg Bull. Dept. Agric. Indes Neerl. 35:1-6 (Syntypes?, Java): Strohmever, 1910, Ent. Blätt. 6:186. Synonymy
Stephanoderes cooki Hopkins, 1915, U.S. Dept. Agric. Rept. 99:27 (Holotype, female; Mount Coffee, Liberia; U.S. Nat. Mus., 7592); Schedl, 1959, Trans. Ent. Soc. London 11:485. Synonymy
Xyleborus cofeicola Campos Novaes, 1922, Bol. Agric. Sao Paulo 23:67 (Not seen); Costa Lima. 1924, Chacaras e Quintaes 30:316. Synonymy
Stephanoderes punctatus Eggers, 1924, Ent. Blätt. 20:101 (Lectotype: Eala, Congo; U.S. Nat. Mus., (60, 160), by Anderson and Anderson, 1971, Smithsonian Contrib. Zool. 94:27); Wood. 1972, Great Basin Nat. 32:48. Synonymy
Diagnosis.- This species is distinguished from obscurus (Fabricius) by the brightly shining elytral surface, by the slightly longer, more widely spaced, much more slender elytral bristles, by the slightly larger average size, and by other characters indicated below.

Female.- Length $1.4-1.7 \mathrm{~mm}, 2.3$ times as long as wide; mature color black.

Frons and pronotum as in obscurus except pronotal disc not reticulate, more nearly shining. Elytra as in obscurus except interstriae smooth, brightly shining (centers of strial punctures usually reticulate as in obscurus); interstrial bristles slender, each at least eight times as long as wide, spaced between rows by length of a bristle, spaced within a row by a slightly smaller distance.

Male.- Dwarfed as in male obscurus but otherwise similar to female.

Distribution.-Guatemala, Jamaica, Colombia, Brazil, Micronesia, Philippines, Indonesia, Africa.

GUATEMALA: Parts of Escuintla, Retalhulen, Sololá, and Suchitepequez provinces. HONDURAS: Several localities.

Hosts. - Coffee beans.
Biology.- Only the fruits (berries) of coffee are attacked. Previously mated females bore into green fruits near the stem. A small cavity is excavated where up to 120 eggs may be deposited in one fruit. The larvae extend the parental tunnel as they consume the bean. Pupation and emergence are followed by mating with the flightless sibling males inside the brood chamber. It is not entirely clear whether the mated females spend the remainder of the year in the brood chamber in fruit on the ground, emerge to infest unpicked fruit hanging on the plant, or estivate
in litter in and near the plantation area. Apparently only one generation occurs each year. In severe infestations losses can be as high as 100 percent.

## 12. Hypothenemus dolosus Wood

Hypothenemus dolosus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):21 (Holotype, female; Pandora, Limón, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from opacus (Eichhoff) by the absence of pits behind the asperities on the pronotal summit, by the more coarsely, deeply punctured pronotal disc, by the smooth, shining el $y$ tral surface, and by the absence of scalelike setae on the pronotum.

Female.- Length $1.6-1.7 \mathrm{~mm}, 2.3$ times as long as wide; color dark brown to black.

Head and pronotum as in opacus except asperities at pronotal summit not associated with deep pits; some punctures between summit and base form deep pits but without associated asperities; posterolateral areas subshining, deeply, closely, coarsely punctured. Vestiture all hairlike.

Elytra as in opacus except surface of interstriae smooth, shining; punctures on discal interstriae 2 usually uniseriate; declivital surface minutely granulate.

Distribution.- Veracruz to Costa Rica.
MEXICO: Chiapas: 21 km N Ocozocoautla, 2-vil-69. D. E. Bright. Veracruz: Dos Amates, 5-V-69, Lago Catemaco, 13-V-69, 16 km N Sontecompana, 20-V1-69, all by D. E. Bright. HONDURAS: La Lima, Cortéz, 5-V-64, 200 m . No. 575, Swietenia, S. L. Wood. COSTA RICA: Pandora, Limón, 23-VIII-63, 50 m, No. 140, Mimosa, S. L. Wood.

Hosts.- Mimosa sp., and Swietenia sp.
Biology. - Essentially as in dissimilis.
Notes.- The above treatment was based on the type series of 13 specimens and on 12 other specimens.

## 13. Hypothenemus opacus (Eichhoff)

Stephanoderes opacus Eichhoff, 1872, Berliner Ent. Zeitschr. 15:132 Lectotype, female; Nov. Grenada; Institute Roval de Sciences Naturelles. Brussels, present designation)
Diagnosis.- This species is distinguished from bolivianus Eggers by the much more broadly rounded pronotal summit, with smaller, more numerous asperities, by the small circular pit behind each asperity at the
summit (these normally fill with boring dust and resemble recumbent, white scales), and by the slightly stouter interstrial scales.

Female.- Length $1.6-1.9 \mathrm{~mm}, 2.3$ times as long as wide; color dark brown to almost black.

Head as in bolivianus and related species.
Pronotum 0.90 times as long as wide; widest one-third length from base, sides moderately arcuate, rather broadly rounded in front; anterior margin armed by six teeth, median pair largest, lateral pair minute; summit very broadly rounded, with numerous very fine asperities in summit area, a moderately large, subcircular pit behind each, pits normally filled with white boring dust; posterior areas minutely granulate, with several granules behind summit, fine, shallow punctures in remaining areas. Vestiture hairlike, with slender scales intermixed only in posterior areas.

Elytra 1.4 times as long as wide; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae distinctly impressed, punctures small, shallow, usually obscure; interstriae convex, minutely rugose, twice as wide as striae, punctures small, rather obscure, uniseriate except moderately confused on 2 and 3. Declivity convex, rather steep; essentially as on disc, all interstrial punctures uniseriate. Vestiture of rows of minute strial hair and rows of erect scales; each scale as long as distance between rows, more closely spaced within a row, each about four to six times as long as wide.

Male.- Similar to female except 1.5 mm , 2.1 times as long as wide; eye reduced in size; pits on pronotal summit partly or entirely absent; interstrial scales slightly longer, more slender.

Distribution.- Costa Rica to Colombia and Venezuela.

COSTA RICA: Beverley, Dominical, Finca Gromaco on Río Coto Brus, Guápiles, Playón, Rincón de Osa, Río Damitas in Dota Mts., San Isidro del General, Tapantí. PANAMA: Concepción, Paraiso, Porto Bello. OTHER AREAS: Colombia, Venezuela.
Hosts.- Calliandra confusa, Cassia sp., coffea aribica, Inga sp., Mimosa spp., Nectandra sp., Ochroma sp., Protium sp., and Tovomita guianensis.

Biology. - Essentially as in dissimilis.
Notes.- The above treatment was based on the two syntypes in the Chapuis collection
at Brussels and on 109 other specimens. The first syntype in the Chapuis collection is here designated as the lectotype of Stephanoderes opacus Eichhoff.

Because at least one cotype of Stephanoderes bolivianus Eggers in the Schedl collection is a misidentified specimen of opacus, one might expect to find other material of this species incorrectly placed as a result of that error. The holotype of bolivianus is quite different.

## 14. Hypothenemus squamosus (Hopkins)

 Fig. 19.4Stephanoderes squamosus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:26 (Holotype, female; Cayamas, Cuba; U.S. Nat. Mus., 7566)
Diagnosis.- This species is distinguished from solocis Wood by the more broadly convex elytral declivity, with the apical costal margin not strongly elevated, and by the smaller interstrial granules on the declivity that are equally developed on all interstriae.

Female.- Length $1.3-1.5 \mathrm{~mm}, 2.3$ times as long as wide; color dark brown to almost black.
Head and pronotum essentially as in interstitialis, except asperities slightly smaller; anterior margin armed by six teeth; posterior areas reticulate-granulate, punctures fine, obscure. Vestiture in posterior areas of fine, short hair intermixed with rather broad scales, each scale slightly more than twice as long as wide.

Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal three-fourths, rather broadly rounded behind; striae slightly impressed toward declivity, punctures small, moderately deep; interstriae almost twice as wide as striae, somewhat rugose, punctures moderately large, uniseriate, feebly vulcanate at base, more strongly vulcanate toward declivity. Declivity very broadly convex, rather steep; striae rather strongly, narrowly impressed, punctures obscure; interstriae distinctly convex, with close, subvulcanate, squamiferous granules; interstriae 9 rather weakly elevated from 3 to suture. Vestiture of rows of minute strial hair and rows of longer, erect, interstrial scales; scales on declivity twice as long as on disc, each declivital scale as long as distance between rows,
spaced within a row by half that distance, each two to four times as long as wide; scales in ventrolateral area of declivity much longer.

Male.-Similar to female except $0.90-1.15 \mathrm{~mm}, 2.3$ times as long as wide; eye reduced in size, one or more teeth missing from anterior margin of pronotum; elytral declivity not as steep; sculpture not as sharply defined.

Distribution.-S Florida, Tamaulipas, Veracruz, Colima, and Cuba.

USA: Florida: Everglades N.P., Key Largo, Matecumbe Key. MEXICO: Colima: 3 km W Armeria. Tamaulipas: Encinal. Veracruz: Cerro Gordo, Huatusco, 3 km S Rinconada, 24 km W Veracruz. CUBA: Cayamas.

Hosts.-Ardisia paniculata, Dipholis salicifolia, Galactia spiciformis, Ichthyomethia communis, Lysiloma bahamensis, Parthenocissus quinquefolia, Phoradendron sp., Pithecellobium unguis-cati, Serjania sp., Torrubia longifolia, Vismia sp.

Biology.- Essentially as in dissimilis.
Notes. - The above treatment was based on the holotype of squamosus and on 51 other specimens. Specimens from Colima have the scales on the elytral declivity slightly shorter than those from Florida, but the transition is gradual and apparently indicates nothing more than a cline within a continuous distribution.

## 15. Hypothenemus solocis Wood

Hypothenemus solocis Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):21 (Holotype, female; 3 km or 2 miles W Armeria, Colima, Mexico: Wood Coll.)
Diagnosis.- This species is distinguished from squamosus Hopkins by the more strongly impressed discal striae, by the slightly larger interstrial tubercles on both disc and declivity, by the more narrowly convex declivity with the costal margin near the apex much more strongly elevated, and by the reduction in size of tubercles toward the apices of interstriae $2,4,5,6$, and 8 .

Female.- Length $1.3-1.5 \mathrm{~mm}, 2.3$ times as long as wide; color dark reddish brown.

Head and pronotum as in squamosus except surface of posterior areas more coarsely granulate.

Elytra 1.5 times as long as wide; sides almost straight and parallel on basal two-thirds,
distinctly constricted near middle of declivity, rather narrowly rounded behind; striae distinctly impressed, punctures moderately large, shallow, indistinct; interstriae as wide as striae, distinctly convex, entire surface granulate, punctures uniseriate, granulate. Declivity rather narrowly convex, steep; interstriae more narrowly convex, particularly 1 and 3, granules larger except obsolete toward apices of $2,4,5,6$, and 8 , posterior part of 9 with costal margin rather strongly elevated. Vestiture of rows of minute, fine, strial hair, and rows of erect, interstrial scales; each scale on declivity slightly shorter than distance between rows, slightly longer than distance between scales within a row, each about two to three times as long as wide.

Distribution.- Sinaloa to Colima.
MEXICO: Colima: 3 km W Armeria, 28-V1-65, 70 m , No. 135, Phoradendron, S. L. Wood. Nayarit: 27 km E San Blas, 25-VI1-53, S. L. Wood; Los Corchos, 10-VI1-65, 7 m , No. 206, tree branch, S. L. Wood; 48 km N Tepic, 11-VIl-65, 500 m , No. 226 in Inga, No. 228 in iSerjania, S. L. Wood: 8 km S Río Santiago Ferry, 27-XI-48. Sinaloa: Concha, 20-VII-53, 15 m, S. L. Wood.
Hosts. - Inga sp., Phoradendron sp., Serjania sp.

Biology.- Presumably as described for dissimilis.

Notes. - The above treatment was based on the type series of 10 female specimens.

## 16. Hypothenemus crudiae (Panzer)

Bostrichus crudiae Panzer, 1791, Naturforscher 25:35-38 (Syntypes: India occidentali; presumably lost)
Bostrichus plumeriae Nördlinger, 1856, Nachtr. Ratzeburgi Forstinsekten, p. 74 (Syntypes; Venezuela) (Probable synonymy based on specimens determined by Eggers); Wood, 1972, Great Basin Nat. 32:44. Synonymy
Cryphalus hispiduhus LeConte, 1868, Trans. Amer. Ent. Soc. 2:156 (Syntypes; District of Columbia, Georgia, Louisiana; Mus. Comp. Zool.); Eichhoff, 1896, Proc. U.S. Nat. Mus. 18:608. Synonymy
Hypothenemus namus Hagedorn, 1909, Deutsche Ent. Zeitschr. 1909:744 (Syntypes, female; Argentina; La Plata); Schedl, 1952, Ent. Blätt. 47-48:162. Synonymy
Stephanoderes differens Hopkins, 1915, U.S. Dept. Agric. Rept. 99:25 (Holotype, female: San Bernardino, Paraguay; U.S. Nat. Mus., 7541); Wood, 1972, Great Basin Nat. 32:44. Synonymy
Stephanoderes guatemalensis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:26 (Holotype, female; Treces Aguas, Alta Verapaz, Guatemala; U.S. Nat. Mus., 7380 ); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1041. Synonymy

Stephanoderes brasiliensis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:26 (Holotype, female: Perambuco, Brazil; U.S. Nat. Mus., 7372); Wood. 1954, Uniw. Kansas Sci. Bull. 36(2):1041. Synonymy
Stephanoderes paraguayensis llopkins. 1915, U.S. Dept. Agric. Rept. 99:26 (Holotype, female; San Bernardino, Paraguay: U.S. Nat. Mus.. 7377); Wood. 1972, Great Basin Nat. 32:44. Synonymy
Stephunoderes lecontei Hopkins, 1915, U.S. Dept. Agric. Rept. 99:27 (Holotype. female; Jefferson County, West Virginia: U.S. Dept. Agric., 7357); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1041. Synonymy
Stephanoderes polyphagus Costa Lima, 1924 (nec Eggers. 1924), Chac. Quint. 30:316 (not seen); Wood. 1972, Creat Basin Nat. 32:44. Synonymy
Stephonoderes fallax Costa Lima, 1924, Chac. Quint. 30:414 (Replacement name for polyphagus Costa Lima)
Stephanoderes largipemis Piza Junior, 1924, Rev. Sox. Rur. Brasileira 5:354 (Syntypes?, Brazil); Costa Lima, I925, Bol. Minist. Agric. Rio de Janeiro 14:197. Synonymy
Stephanoderes uniseriatus Eggers, 1924, Ent. Blätt. 20:103 (Lectotype, female: Luebo, Congo, U.S. Nat. Mus., 60169, designated by Anderson and Anderson, 1971, Smithsonian Contrib. Zool. 94:35); Wood. 1972, Great Basin Nat. 32:44. Synonymy
Stephanoderes hicatea Beeson, 1935, Bull. Bishop Mus. 142:105 (llolotype, female; Tahauku, Hivaoa, Marquesas lslands: Bishop Mus); Wood, 1972, Great Basin Nat. 32:44. Synonymy
Stephanoderes lebronncei Beeson, 1935, Bull. Bishop Mus. 142:104 (Syntypes; Tahuata and Uapou, Marquesas Islands; Bishop Mus.); Wood, 1972. Great Basin Nat. 32:44. Synonymy
Stephanoderes hacuiiensis Schedl, 1941, Proc. Hawaiian Ent. Soc. 11:112 (Syntypes?. female: Oahu, Honolulu; Bishop Mus.?): Wood, 1960, Insects of Micronesia 18(1):38. Synonymy
Diagnosis.- This abundant, widespread, economically important species is distinguished from seriatus (Eichhoff) by the shallowly concave lower frons (concave on longitudinal axis only), by the presence of a small, often poorly developed median tubercle at upper level of eyes, this tubercle partly incised on lower side by a median groove of variable length, and by the somewhat more slender interstrial scales.

Female.- Length $1.4-1.6 \mathrm{~mm}, 2.3$ times as long as wide; color dark brown to almost black, vestiture pale.

Frons convex except shallowly impressed in median area, weakly concave on longitudinal axis from upper level of eyes to epistoma, a weak to moderately strong median tubercle at upper level of eyes, a median groove commencing at summit of tubercle and extending
about half distance to epistomal margin (variable); surface strongly rugose-reticulate above, becoming more nearly punctate toward epistoma; vestiture inconspicuous.

Pronotum 0.93 times as long as wide; widest one-third of length from base, sides moderately arcuate, gradually converging to rather broadly rounded anterior margin; anterior margin armed by four to eight coarse teeth of about equal size; summit at middle, rather high; asperities on anterior slope abundant, rather small for this genus; posterior area subreticulate, small, isolated, rather numerous granules behind summit, granules smaller and intermixed with a few shallow punctures in lateral areas. Vestiture hairlike, in posterior areas with a few scales intermixed.

Elytra 1.5 times as long as wide; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae feebly if at all impressed, punctures rather coarse, moderately deep; interstriae as wide as striae, almost smooth, punctures fine, uniseriate, usually feebly granulate, particularly toward declivity. Declivity convex, steep; essentially as on disc. Vestiture of rows of minute recumbent strial hair and rows of erect interstrial scales; each scale almost as long as distance between rows, slightly closer within a row, each two to three times as long as wide, not noticeably longer laterally.

Male.-Similar to female except 1.0-1.1 $\mathrm{mm}, 2.2$ times as long as wide; eye reduced in size; pronotal teeth often reduced in number; elytral declivity not as steep; striae and other features less precisely formed; pubescence longer, more slender.

Distribution.-SE United States to Argentina, Hawaiian Islands, Micronesia, and Africa.

USA: Alabama, Arkansas, District of Columbia, Florida, Georgia, Indiana, Kansas, Kentucky, Louisiana, Maryland, Mississippi, New Jersey, New York, North Carolina, Pennsylvania, South Carolina, Tennessee, Texas, Virginia, West Virginia. MExıCO: Chiapas, Colima, Jalisco, Michoacán, Oaxaca, San Luis Potosí, Tamaulipas, Veracruz. CENTRAL AMERICA: Guatemala, Honduras, Nicaragua, Costa Rica, Panama. OTHER AREAS: Argentina, Brazil, British Guiana, Colombia, Congo, Cuba, Ecuador, Ghana, Hawaiian Islands, Marquesas lslands, Micronesia, Paraguay, Puerto Rico, Trinidad, Venezuela, West Indies (Grenada).

Hosts.- Abutilon mollissimum, Aeacia farnesiana, A. sp., Achras sapota, Adenanthera pavonina, Aloe vera, Astragalus sp.,

Bauhinia grandiceps, B. krugi, Betula sp., Bidens pilosa, Bignonia sp., Boehmeria scabra, Bucida buceras, Bursera sp., Carya spp., Cassia nodosa, Cinnamomum camphora. Citrus sp., Clerodendron squamatum, Crataegus sp., Dalbergia ecastophyllum, Derris sp., Dioclea megacarpa, Diphysia robinioides, Ficus spp., Glycine max, Grewia asiatica, Inga spp., Juglans nigra, Magnolia sp., Malus spp., Mangifera indica, Morus rubra, Passiflora latifolia, Phalocarpus septentrionis, Pinus taeda, Prumus persica, Quercus spp., Quisqualis indica, Rhizophora mangle, Richinus communus, Schleichere trijuga, Serjania racemosa, Sida rhombifolia, Smilax sp., Theobroma cacao, Wisteria sp., Yucca sp.

Biology.- Specimens of this abundant and important species may attack small branches, twigs, vines, weeds, or other plants, where gallery systems similar to those of dissimilis are formed, or they may attack a wide variety of seeds, pods, or other fruiting bodies, where slightly modified galleries are formed. The broad host range, high fecundity, and ability to spread through commerce have made this species economically important in tropical and subtropical agriculture. Its importance in forestry apparently is limited to its effect on seed production.

Notes.- The above treatment was based on the holotypes of differens, guatemalensis, brasiliensis, paraguayensis, lecontei, and hivaoea, on syntypes of hispidulus, hawaiiensis, polyphagus, and libroneci, on the lectotype uniseriatus, and on Eggers's specimens of crudiae and plumeriae (Eggers had the opportunity to see these type series, but whether he did or did not is not known). In all, 478 pinned specimens were examined, as well as several hundred in alcohol.

In general, specimens from southern South America have the frontal tubercle very poorly developed or almost absent and the transverse impression on the lower half of the frons may be poorly developed. Material from the Pacific islands usually has the frontal groove rather short and broad. These characters in series from both areas tend to be more variable than in material from other regions.

## 17. Hypothenemus obscurus (Fabricius)

Hylesinus obscurus Fabricius, 1801, Systema Eleuth. 2:395 (Lectotype, female; Essequibo, British Guiana, published as Americae meridionalis; Copenhagen Mus., designated by Wood, 1972, Great Basin Nat. 32:49)
Stephanoderes asperulus Eichhoff, 1872, (nec LeConte, 1868), Berliner Ent. Zeitschr. 15:133 (Lectotype, female; in Cassia, from northern South American; Institut Royal des Sciences Naturelles, Brussels, present designation); Wood, 1977, Great Basin Nat. 37:513. Synonymy
Stephanoderes cassiae Eichhoff, 1878, Mém. Soc. Roy. Sci. Liége (2)8:152 (Replacement name for asperulus Eichhoff): Wood, 1977, Great Basin Nat. 37:513. Synonymy
Hypothenemus kïnnemanni Reitter, 1902, Wiener Ent. Zeit. 21:140 (Lectotype, female; Bremen, Germany, in Brazil nuts; Budapest Mus., designated by Wood, 1972. Great Basin Nat. 32:49); Wood, 1972, Great Basin Nat. 32:49. Synonymy
Stephanoderes moschatae Schaufuss, 1905, Ins. Börse, 1905:8 (reprint p. 2) (Holotype, female; Guadeloupe: presumably lost with Hamburg Mus.); Wood, 1972. Great Basin Nat. 32:49. Synonymy
Stephanoderes rufescens Hopkins, 1915, U.S. Dept. Agric. Rept. 99:29 (Holotype, female; Allegheny, Pennsylvania; U.S. Nat. Mus., 7527); Wood, 1972, Great Basin Nat. 32:49. Symonymy
Stephanoderes buscki Hopkins, 1915, U.S. Dept. Agric. Rept. 99:30 (Holotype, female: Trinidad. West Indies; U.S. Nat. Mus., 7537); Wood. 1972, Great Basin Nat. 32:49. Synonymy
Stcphanoderes amazonicus Eggers, 1934, Ent. Blätt. 30:78 (Lectotype, female; Manaos, Brazil; U.S. Nat. Mus., 60142; designated by Anderson and Anderson, 1971. Smithsonian Contrib. Zool. 94:4); Wood, 1972. Great Basin Nat. 32:49. Synonymy
Hypothenemus emarginatus Schedl. 1942, Tijdschr. Ent. 85:11 (Holotype, female; Buitenzorg, Java; Schedl Coll.); Wood, 1966, Great Basin Nat. 26:29. Synonymy
Diagnosis.- This species is distinguished from seriatus (Eichhoff) by the minutely rugose or rugose-reticulate elytral surface, and by the deeper, more elongate frontal groove.

Female. - Length $1.2-1.4 \mathrm{~mm}, 2.3$ times as long as wide; color very dark brown.

Frons broadly convex, a deep, narrow, median groove from upper level of eyes almost to epistoma; surface finely rugose-reticulate, becoming more nearly punctate toward epistoma; vestiture inconspicuous. Pronotum as in crudiae and seriatus except entire surface conspicuously rugose-reticulate. Elytra as in crudiae and seriatus except entire surface densely, very minutely rugose to granulatepunctate; erect interstrial scales each four to six times as long as wide.

Male.- Similar to female except differing as indicated for crudiae.

Distribution.- Florida and Costa Rica and Puerto Rico to Brazil.

USA: Florida: Miami. COSTA RICA: Río Damitas in Dota Mits., San José, 18-11-64, 250 m, No. 433, Hymenen pods, S. L. Wood. PANAMA: Canal Zone: Balboa Heights, 5-X-17, H. Morrison: Paraíso, 2-IV-11, E. A. Schwarz. OTHER COUNTRIES: Dominican Republic, Jamaica, Puerto Rico, Colombia, Venezuela, Brazil, and intercepted in Brazil nuts throughout the world.

Hosts.-Bertholletia excelsa, Hymenea courbaril, Myristica fragrans, Tamarindus indica, Theobroma cacao.

Biology.- This economically important species breeds in the fruiting pods and seeds of a wide variety of hosts. Apparently it is also capable of breeding in the twigs of certain hosts, although such records have not adequately been confirmed. It is best known from interceptions in Brazil nuts.

Notes.- The above treatment was based on the holotypes of rufescens and buschi, on the lectotypes of obscurus, asperulus, kïnnemanni, and amazonicus, and on several specimens of moschatae determined by Schedl (who had examined the type and/or homotypes). A total of 271 specimens was examined.

The Fabricius type series of obscurus now includes three specimens belonging to two closely related species. The first two are identical. The third specimen is of a different species, possibly crudiae (Panzer), but the frontal tubercle is almost obsolete and the frons is largely concealed by the pronotum. Because the author presumably had the first two specimens in mind when the species was named and because the identity of the third specimen is not clear, the second specimen was designated as the lectotype of Hylesinus obscurus Fabricius. The first specimen has the right elytron missing and a large hole in the left one; consequently, it was not selected.

Three female syntypes of asperulus Eichhoff in the Chapuis collection at Brussels were examined. The first and third specimens are of obscurus and the second is of seriatus (Eichhoff); the third syntype is in the best condition and is here designated as the lectotype of Stephanoderes asperulus Eichhoff. Eichhoff originally labeled these specimens as Cryphalus asperulus, a preoccupied name,
but published the name as Stephanoderes asperulus. He incorrectly assumed his name was a junior homonym and replaced it with cassiae.

Several series of this species have been intercepted in imported seeds at Miami, Florida, and one series of living specimens was taken from native plants at Miami. Whether or not it can maintain its identity without being swamped by seriatus remains to be seen. Several series of this species, seriatus, and intermediate forms were taken from cof fee beans in western Guatemala. Apparently this area is in a zone of overlap between the two forms, and some hybridization may be occurring. Additional time and specimens are required to determine whether or not a taxonomic change is required.

## 18. Hypothenemus multidentatus (Hopkins)

Stephanoderes multidentatus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:28 (Holotype, female; Tampico, Tamaulipas, Mexico; U.S. Nat. Mus., 7532)
Stephanoderes ferrugineus Hopkins, 1915 (nec Hopkins, 1915:20). U.S. Dept. Agric. Rept. 99:29 (Holotype, female; Livingston, Cuatemala; U.S. Nat. Mus., 7535); Wood, 1972, Great Basin Nat. 32:49. Synonymy
Stephanoderes nitidifrons Hopkins, 1915, U.S. Dept. Agric. Rept. 99:31 (Holotype, female; Tampico, Tamaulipas, Mexico; U.S. Nat. Mus., 7546); Wood, 1972, Great Basin Nat. 32:49. Synonymy Hypothenemus hopkinsi Browne, 1963, Ent. Bericht. 23:53. Replacement name for ferrugineus Hopkins.
Diagnosis.- This species is distinguished from seriatus (Eichhoff) by the larger size and smaller strial punctures. There is a strong possibility it represents nothing more than a size variation in a normal population.

Female.- Length $1.6-1.8 \mathrm{~mm}, 2.3$ times as long as wide; color very dark brown.

Head and pronotum as in seriatus except anterior margin of pronotum usually with four teeth (in six of eight specimens), and posterolateral areas more brightly shining. Elytra as in seriatus except strial punctures averaging smaller; declivital interstrial scales four to six times as long as wide.

Distribution.- Tamaulipas to Colombia.
MEXICO: Puebla: 11 km W Villa Juarez, 25-VI-53, 400 m, S. L. Wood. Tamaulipas: Tampico, 24, 26-XII, E. A. Schwarz. COLOMBIA: Palermo, V-59, café, F. Vasquez.

Hosts.- Coffea aribica, etc.

Brology. - Specimens were collected from dissimilis-like tunnels in twigs.

Notes.- The above treatment was based on the holotypes of multidentatus, ferrugineus, and nitidifrons and on five other specimens.

## 19. Hypothenemus seriatus (Eichhoff)

Fig. 194

Stephanoderes seriatus Eichhoff, 1872, Berliner Ent. Zeitschr. 15:133 (Lectotype, female: New Orleans, Louisiana: lnstitut Royal des Sciences Naturelles, Brussels, designated by Wood, 1973. Great Basin Nat. 33:177)
Stephanoderes pulterulentus Eichhoff, 1872. Berliner Ent. Zeitschr. 15:1.33 (Syntypes, female: Mexico; presumably lost with Hamburg Mus.); Wood, 1973, Great Basin Nat. 33:177. Synonymy
Stephanoderes culgaris Schaufuss, 1897, Tijdschr. Ent. 40:209 (Syntypes, female: La Digue. Sechelle 1slands; presumably lost with Hamburg Mus.); Wood, 1972. Great Basin Nat. 32:50. Synonymy
Stephanoderes georgiae Hopkins. 1915, U.S. Dept. Agric. Rept. 99:26 (Holotype, female; Georgia; U.S. Nat. Mins., 7385); Wood, 1972, Great Basin Nat. 32:50. Synonymy
Stephamoderes texamus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:26 (Holotype, female; Columbus, Texas; U.S. Nat. Mus., 7373); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1048. Synonymy
Stephanoderes mimutus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:26 (Holotype, female; Cayamas, Cuba, U.S. Nat. Mus., 7366); Wood, 1972. Great Basin Nat. 32:50. Synomymy
Stephanoderes tamarindi Hopkins, 1915, U.S. Dept. Agric. Rept. 99:27 (Holotype, female: Manila, Philippine lslands; U.S. Nat. Mus., 7530); W'ood, 1972. Great Basin Nat. 32:50. Synonymy

Stephanoderes pini Hopkins, 1915, U.S. Dept. Agric. Rept. 99:27 (llolotype, female; Kanawha Station, West Virginia; U.S. Nat. Mus., 7376); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1048. Synonymy
Stephanoderes salicis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:27 (Holotype, female; Morgantown. West Virginia; U.S. Nat. Mus., 7359); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1048. Synonymy
Stephanoderes floridensis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:27 (Holotype, female: Haw Creek, Florida; U.S. Nat. Mlus.. 7375); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1048. Synonymy
Stephanoderes fiebrigi Hopkins, 1915, U.S. Dept. Agric. Rept. 99:27 (Holotypes, female: San Bernardino, Paraguay; U.S. Nat. Mus., 7387); Wood, 1972, Great Basin Nat. 32:50. Synonymy
Stephanoderes ficus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:28 (Holotype, female; Alabama; U.S. Nat. Mus., 7374 ): Wood. 1954. Univ. Kansa, Sci. Bull. 36(2):1048. Synonymy

Stephanoderes soltaui Hopkins, 1915, U.S. Dept. Agric. Rept. 99:28 (Holotype, female; New Orleans, Louisiana; U.S. Nat. Mus., 7529); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1048. Synonymy
Stephanoderes hucasi Hopkins, 1915, U.S. Dept. Agric. Rept. 99:28 (Holotype, female: southern United States; U.S. Nat. Mus., 7531); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1048. Synonymy
Stephanoderes cirentis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:28 (Holotype, female: Lakeland, Florida: U.S. Nat. Mus., 7558): Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1048. Synonymy
Stephanoderes pecanis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:29 (Holotype, female; Orlando, Florida; U.S. Nat. Mus., 7360); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1048. Synonymy
Stephanoderes nitidipennis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:29 (Holotype, female; Cayamas, Cuba; U.S. Nat. Mus., 7533); Wood, 1972, Great Basin Nat. 32:50. Synonymy
Stephanoderes nitidulus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:29 (Holotype, female; Cayamas, Cuba; U.S. Nat. Mus.); Wood, 1977, Great Basin Nat. 37:51.3. Synonymy
Stephanoderes subopacicollis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:30 (Holotype, female, Cavamas, Cuba: U.S. Nat. Mus.): Wood, 1977, Great Basin Nat. 37:513. Synonymy
Stephanoderes niger Hopkins, 1915, U.S. Dept. Agric. Rept. 99:31 (Holotype, female; Brownsville, Texas; U.S. Nat. Mus., 7382); Wood, 1972, Great Basin Nat. 32:50. Synonymy
Hypothenemus robustus Blackman, 1922, Mississippi Agric. Expt. Sta. Tech. Bull. 11:88 (Syntypes, female; Newton, Mississippi; U.S. Nat. Mus.); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1048. Synonymy
Stephanoderes darwinensis Schedl. 1942, Mitt. München Ent. Ges. 32:178 (Syntypes; Australia); Wood, 1972, Great Basin Nat. 32:50. Synonymy
Stephonoderes andersoni Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1045 (Holotype, female; Coconut Grove, Florida; U.S. Nat. Mus.); Wood, 1972, Great Basin Nat. 32:50. Synonymy
Stephanoderes liquidambarac Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1046 (Holotype, female; Jacksonboro, South Carolina; Snow Ent. Mus., Univ. Kansas); Wood, 1972, Great Basin Nat. 32:51. Synonymy
Diagnosis.- This common, widely distributed species is distinguished from multidentatus Hopkins by the smaller size and by the larger strial punctures. From obscurus (Fabricius) this species is distinguished by the smoother elytral surface and by the shorter, less well-developed (often obsolete) frontal groove.

Female.- Length $1.3-1.6 \mathrm{~mm}, 2.4$ times as long as wide; color very dark brown.

Head as in obscurus except median groove shallow, varying from half as long to entirely
obsolete, punctures from obscure to rather coarse. Pronotum as in crudiac (Panzer).

Elytra as in crudiae; strial punctures coarse, rather deep; interstriae as wide as striae, almost smooth, shining, punctures fine, uniseriate. Interstrial scales varying from two to six times as long as wide, local clones usually exhibiting little or no variation, scales longer and more slender in posterolateral areas.

Male.- Similar to female but differing as indicated for crudiae.

Distribution.- Texas and West Virginia to Brazil, Hawaii to Australia, Indonesia, and Madagascar.

USA: Alabama, Arkansas, Delaware, Florida, Georgia, Kentucky, Louisiana. Mississippi, North Carolina, South Carolina. Texas, Virginia, West Virginia. MEXICO: Chiapas, Jalisco, Nayarit, Oaxaca, Puebla, San Luis Potosí, Tamat:lipas, Veracruz, Yucatan. CENTRAL AMERICA: Guatemala, Honduras, El Salvador, Costa Rica, Panama. OTHER AREAS: Australia, Barbados, Brazil, Colombia, Cuba, Fiji 1slands, Haiti, Hawaiian 1slands, lvory Coast, Java, Madagascar, Micronesia, Paraguay, Philippine Islands, Puerto Rico, Virgin 1slands.

Hosts.- Acacia farnesiana, Acras sapota. Acrocomia sclerocarpa, Alcurites fordii, Bauhinia tomentosa, Bursera sp., Cajanus cajon, Calliandra confusa, Callicarpa sp., Canavalia sp., Carya spp., Cecropia sp., Citrus aurantifolia, Coccothrinax alta, Cordia sp., Dipholis salicifolia, Eleagnus pungens, Erythrina sp., Eugenia buxifolia, Ficus spp., Galactia spiciformis, Guacea quara, Hyracreptans sp., Ipomoea cathartica, Juglans nigra, Liquidambar styraciflua, Maclura pomifera, Mangifera indica, Muouna sp., Ochroma sp., Ocotea catesbiana, Persea americana, P. borbonea, Philabertella clausa, Pinus spp., Pithecellobium guadeloupense, Prunus persica, Quercus spp., Rhammus sp., Saba parviflora, Salix sp., Seriania sp., Sida rhombigolia, Tectona grandis, Theobroma cacao, Thespersia pulpulnea, Trachylobium narrucosum, Trema floridana, Trichilia arborea, Wisteria sp., Urena sp., Yucca sp.

Biology. - This species is most commonly taken in twigs and branches, but it may also breed in pods, seeds, herbaceous weeds, and other plant material. The habits are essentially as in crudiae.

Notes. - The above treatment was based on the holotypes of georgiae, texanus, tamarindi, pini, salicis, floridensis, soltani, lucasi, virentis, pecanis, niger, robustus, andersoni,
and liquidambarae, on the lectotype of seriatus, on syntypes of emarginatus and darwinensis, and on specimens of pulverulentus and vulgaris identified by Eggers, and on 302 other specimens.

All previous authors, including myself, have recognized several species in what is here grouped into a single species. The frontal area varies in punctation and in the presence or absence of a median groove and/or shining area, and the elytral scales vary from two to six times as long as wide. Most series from a given locality may tend to be constant in these characters, and may contrast with other series from the same or neighboring areas. Other one-gallery series or series from neighboring localities may exhibit virtually every known variation. This species evidently is at least partly parthenogenetic and, when mating does occur, it normally involves siblings or a mother-son combination. This intense inbreeding apparently results in the observed uniformity of many series. It is presumed that the variable series result from the occasional hybrid matings.

## 20. Hypothenemus sparsus Hopkins

 Fig. 194Hypothenemus sparsus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:20 (Holotype, female; Columbus, Texas; U.S. Nat. Mus., 7368 )

Hypothenemus simitis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:20 (Holotype, female; Victoria, Texas; U.S. Nat. Mus., 7554); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1040. Synonymy
Stephanoderes tridentatus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:31 (Holotype, female: San Diego, Texas; U.S. Nat. Mus., 7.369); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1040. Synonymy
Diagnosis.- This species is almost identical to pubescens Hopkins, but it is distinguished by the slightly larger, deeper strial punctures, by the subvulcanate, discal interstrial punctures, and by the slightly narrower interstrial scales.

Female.- Length $1.1-1.3 \mathrm{~mm}, 2.1$ times as long as wide; color very dark brown.

Frons broadly convex; surface rugose-reticulate, punctures rather obscure, a small, smooth, shining median area often present on lower half; vestiture inconspicuous. Pronotum essentially as in crudiac; four teeth arm anterior margin; scales in posterior area slightly longer than wide.

Elytra 1.3 times as long as wide; sides straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, punctures moderately large, rather deep; interstriae as wide as striae, punctures uniseriate, subvulcanately granulate from base to declivity. Declivity steep, convex; striae weakly impressed; interstriae slightly narrower, granules higher. Vestiture of rows of uniseriate, fine, recumbent strial hair and rows of erect interstrial scales; each scale on declivity about half as long as distance between rows, slightly shorter than distance between scales within a row, each about twice as long as wide.

Distribution. - S Texas to Tamaulipas.
USA: Texas: Columbus, 6-VI. Hubbard and Schwarz: Karnes City, 25-111-51, Ccltis pallida. S. L. Wood; Lexington, 24-111-51, Rhammus, S. L. Wood; San Diego, 19-V, Hubbard and Schwarz: Victoria, 21-111, E. A. Schwarz. MEXICO: Tamaulipas: Encinal, 15-Y1-53. Condalia. S. L. Wood.

Hosts.- Celtis pallida, Condalia sp., Rhammus sp.

Biology. - This species breeds in twigs of trees and shrubs.

Notes. - The above treatment was based on the holotypes of sparsus, similis, and tridentatus, and on eight other specimens.

## 21. Hypothenemus califormicus Hopkins Fig. 194

Hypothenemus califormicus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:19 (Holotype, female; Pomona, California: U.S. Nat. Mus., 7364)
Hypothenemus tritici Hopkins, 1915, U.S. Dept. Agric. Rept. 99:19 (Ilolotype, female; Dallas, Texas; U.S. Nat. Mus., 7526); Wood, 195t, Univ. Kansas Sci. Bull. 36(2):1055 (Sulspecies); Wood. 1972, Great Basin Nat. 32:44. Synonymy
Hypothenemus thoracicus Hopkins, 1916, in Blatchley and Leng, Rhynchophora of North Eastern America, p. 598 (Holotype, female; Clark Co.. Indiana; U.S. Nat. Mus., 7457); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1055. Synonymy
Diagnosis.- This species is distinguished from all other American species in the genus by the combination of the coarsely, deeply punctured posterolateral areas of the pronotum, the slender body form, and the long, slender interstrial scales.

Female.- Length $1.0-1.4 \mathrm{~mm}, 2.5$ times as long as wide; color dark brown to black.

Frons convex above, shallowly, transversely impressed on lower half; median line
shining and indistinctly elevated in impressed area; remaining surface reticulate-granulate, particularly in marginal areas, becoming more nearly punctate toward ventromedian area; vestiture inconspicuous.

Pronotum 1.0 times as long as wide; widest one-third length from base, sides moderately, evenly arcuate, rather broadly rounded in front; anterior margin armed by six coarse teeth of equal size; summit in front of middle, not high; posterior and lateral areas closely, rather coarsely, deeply punctured, with fine, indistinct granules intermixed. Vestiture of hair and, on posterior heif, with slender, erect scales intermixed.

Elytra 1.6 times as long as wide; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, punctures small, shallow; interstriae about one and one-half times as wide as striae, smooth, punctures fine, uniseriate. Declivity convex, steep; essentially as on disc. Vestiture of rows of fine, short, strial hair on disc, with a few similar supplemental interstrial setae on lateral areas of declivity, and rows of erect interstrial scales; each scale slightly longer than distance between rows and between scales within a row, each about six times as long as wide.

Male.- Similar to female except $0.75-0.85 \mathrm{~mm}, 2.2$ times as long as wide; eye reduced; funicle often 3 -segmented, club smaller, more slender; one or more marginal teeth on pronotum absent; pubescence longer, more slender.

Distribution.-S California, Texas, and New Jersey to Florida, Veracruz, and Michoacán; Africa.

USA: California: Laguna, Pasadena, Pomona, Redondo, Westwood Hills. Distriet of Columbia: Washington. Florida: Gainesville, Homestead, Key Largo. Key Vaca, Key West, Long Kev, Matecumbe Key, Perrine, Plantation Key. Indiana: Clark Co. Kansas: Lawrence, Wellington. Kentueky: Fulton. Maryland: College Park. Missouri: Charleston. New Jersey: Haddon Heights. South Carolina: Charleston, Frogmore, Isle of Palms, Pawley's Beach. Tennessee: Chapin Sanctuary at East Ridge. Texas: Alamo. Big Bend N.P., Boca Chica, Brownsville, Dallas, Kerrville, Pharr, Port Arthur. Virginia: Spotsylvania, Lynchburg. MEXICO: Miehoaeán: Quiroga. Mexico: Morelos. Tamaulipas: Victoria. Veracruz: 5 km E Orizaba. OTHER AREAS: Israel, Liberia.
Hosts.- Aloe vera, Bauhinia alba, Bidens pilosa, Boehmeria seabra, Cajanus cajon, Cappria bifolia, Galactia spiciformis,

Ipomoea cathartica, I. litoralis, Iva imbricata, Malvastrum sp., Mangifera indica, Paspalum vaginatum, Quisqualis indica, Salix babylonica, Uniola paniculata, Verbena sp., Zea mays.

Brology.- This species breeds in weed stocks, twigs of trees, and shrubs, vines, etc. The tunnels vary with the type of host material, but the habits are basically as in eruditus.

Notes. - The above treatment was based on the holotypes of californicus, tritici, and thoracicus, and on 96 other specimens.

One specimen of this species was seen from Israel and one from Liberia in western Africa. Two syntypes of albipilis Reitter, in the Budapest Museum, described from Syria, differ only by minor characters (although they clearly are specifically distinct). Because californicus is not closely related to any American species, but does appear to have a definite relationship to one or more species from Africa, there is a distinct possibility that it was introduced to North America from Africa. A more thorough knowledge of the African fauna is necessary to answer this question. Separate introductions, from different African sources, to the east and west coasts of the United States could explain the apparent geographical races in America.

## 22. Hypothenemus vesculus Wood

Hypothenemus vesculus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):21 (Holotype, female: Ocosingo Valley, Chiapas, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from nanellus Wood by the smooth, shining posterolateral areas of the pronotum, with the punctures entirely devoid of granulation, by the unimpressed striae, with small, shallow, strial punctures, by flat, smooth interstriae, and by the much more slender interstrial scales.

Female. - Length $1.0 \mathrm{~mm}, 2.2$ times as long as wide; color dark brown.

Frons as in nanellus but surface below upper level of eyes smooth, shining, punctures more distinct. Pronotum as in nanellus except surface smooth, shining, no trace of reticulation, punctures larger, deeper, devoid of granules; scales in posterior area more slender.

Elytra about 1.5 times as long as wide; outline as in nanellus; striae not at all impressed, punctures small, shallow, distinct; interstriae flat, smooth, shining, two to three times as wide as striae, punctures very fine, uniseriate. Declivity rather steep, convex; essentially as on disc. Vestiture of rows of fine, short, strial hair on disc with similar supplemental interstrial hair on lower declivity, and rows of erect interstrial scales; each scale as long as distance between rows, more closely spaced within a row, each about four to six times as long as wide.

Distribution.- Chiapas.
MEXICO: Chiapas: Ocosingo Valley, 7 -VII-50, L. J. Stannard; 16 km S Malpaso, 24-V-69, J. M. Campbell; 5 km N Simojovel, I0-VI-69, J. M. Campbell.

Notes. - The above treatment was based on the holotype and on seven other specimens.

## 23. Hypothenemus ascitus Wood

Hypothenemus ascitus Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. $15(3): 35$ (Holotype, female; Puerto Viejo, Heredia, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from nanellus Wood by the larger size, by the narrower elytral scales and the more abundant hairlike elytral vestiture, and by the smaller, oval, antennal club.

Female.- Length $1.2-1.3 \mathrm{~mm}, 2.2$ times as long as wide; color dark reddish brown, elytra almost black.

Frons convex above, slightly, transversely impressed above epistoma; surface coarsely reticulate above level of eyes, punctate and slightly granulate below; a weak median carina on lower third; vestiture sparse, rather short, hairlike, inconspicuous. Antennal club rather small, oval, 1.5 times as long as wide; eye 1.5 times as long as club.

Pronotum 0.9 times as long as wide; as in nanellus except teeth on anterior margin spaced by distances at least twice basal width of a tooth, and posterior area densely, not clearly punctured, with scattered granules; vestiture of slender scales and bristles.

Elytra 1.2 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae moderately impressed, punctures rather coarse, deep; interstriae
almost as wide as striae, somewhat convex, almost smooth, punctures uniseriate, rather close, minutely subvulcanate. Declivity confined to posterior third, convex, rather steep. Vestiture consisting of uniseriate rows of interstrial scales; each scale about three times as long as wide; and shorter, rather abundant, fine strial and interstrial hair.

Male.-Similar to female except smaller. eye partly reduced.
Distribution.- Costa Rica to Panama.
COSTA RICA: Puerto Viejo, Heredia, $12-\mathrm{-II}-64,70 \mathrm{~m}$. No. 482 , S. L. Wood. PANAMA: Barro Colorado Island. Canal Zone, XII-46, J. Zetek.

Brology.-Specimens were removed from the outermost living bark of a very large living tree. The attack apparently had continued for years without injury to the tree.

Notes.- The above treatment was based on the type series of 12 specimens.

## 24. Hypothenemus nanellus Wood

Hypothenemus nanellus Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):34 (Holotype, female; Turrialla, Cartago, Costa Rica: Wood Coll.)
Diagnosis.- This species is very similar to sparsus Hopkins, but it is distinguished by the smaller size, by the more distinctly punctured posterolateral areas of the pronotum, by the more gradual declivity, and by other characters.

Female.- Length $1.0 \mathrm{~mm}, 2.2$ times as long as wide; color rather dark yellowish brown.

Frons rather weakly convex, a small median pit or impression at upper level of eyes; surface finely rugose-reticulate; sparsely clothed with fine, hairlike setae of moderate length. Antennal club large, 1.1 times as long as wide; eye 1.3 times as long as club.

Pronotum 0.9 times as long as wide; widest on basal third, sides moderately arcuate, rather narrowly rounded in front; anterior margin armed by six teeth, teeth spaced by distances not greater than their basal width; summit at middle, slightly impressed behind; posterior surface rather coarsely reticulate, with small setiferous granules of moderate abundance on disc and lateral areas. Vestiture consisting of small erect scales in posterior areas, small bristles in asperate area.

Elytra 1.3 times as long as wide, 1.5 times as long as pronotum; sides straight and parallel on basal half, then gradually, arcuately converging toward narrowly rounded apex; striae weakly impressed, punctures small, shallow; interstriae about one and one-half times as wide as striae, feebly convex, subreticulate, punctures granulate, granules in uniseriate rows, rather coarse, moderately close. Declivity beginning at middle, convex; essentially as on disc. Vestiture consisting of uniseriate rows of erect interstrial scales and shorter, inconspicuous strial hair; each scale about twice as long as wide, spaced between rows by slightly more than length of a scale, and within rows by slightly less than length of a scale.

Male.- Similar to female except smaller and eye slightly reduced.

Distribution.- Costa Rica.
COSTA RICA: Turrialba, Cartago, 5-l'II-63, 500 m . No. 24, S. L. Wood.

Biology. - Specimens were removed from phloem tissues of dead twigs of a large shade tree.

Notes.- The above treatment was based on the type series of six specimens.

## 25. Hypothenemus pubescens Hopkins Fig. 194

Hypothenemus puhescens Hopkins, 1915, U.S. Dept. Agric. Rept. 99:19 (Holotype. female; Key West, Florida; U.S. Nat. Mus., 7524)
Hypothenemus suhelongatus Hopkins. 1915, U.S. Dept. Agric. Rept. 99:19 (Holotype, female: Victoria. Texas; U.S. Nat. Mus., 758I); Wood, 1972, Great Basin Nat. 32:50. Synonymy
Stephanoderes opacifrons Hopkins, 1915, U.S. Dept. Agric. Rept. 99:25 (Holotype, female; Aguadilla, Puerto Rico; U.S. Nat. Mus., 7565); Wood, I972. Great Basin Nat. 32:50. Synonymy
Diagnosis.- This species is almost identical to sparsus Hopkins, but it is distinguished by the smaller strial punctures, by the absence of discal, interstrial granules, and by the broader interstrial scales. The hairlike elytral ground cover may be restricted to uniseriate rows of strial setae or it may include a few similar interstrial setae.

Female.- Length $1.0-1.1 \mathrm{~mm}, 2.3$ times as long as wide; color yellowish brown.

Frons broadly convex, surface finely ru-gose-reticulate, punctures coarse, not sharply formed.

Pronotum 1.0 times as long as wide; widest near base, sides moderately arcuate, converging slightly, rather broadly rounded in front; anterior margin armed by six equal, very coarse, rather widely spaced teeth; summit at middle; posterior areas reticulate, punctures weakly granulate, those behind summit slightly larger. Vestiture of hair, intermixed on posterior areas with rather broad, erect scales.

Elytra 1.3 times as long as wide; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, punctures small, rather shallow; interstriae very minutely irregular, two to three times as wide as striae, punctures fine, uniseriate. Declivity steep, convex; essentially as on disc, with interstriae narrower. Vestiture of rows of fine, short, strial hair, with or without similar, supplemental, interstrial hair on declivity, and rows of erect, interstrial scales; each scale slightly shorter than distance between rows, much longer than distance between scales within a row, each scale one and one-half times as long as wide.

Male-Similar to female except 0.8 mm , 2.2 times as long as wide; eye reduced in size; funicle usually 3 -segmented, club smaller, more slender; some pronotal teeth absent; vestiture longer, more slender.

Distribution.-S Florida, Texas, Durango, Yucatan, Puerto Rico, and Hawaiian Istands.

USA: Florida: Key Vaca, 29-V1-51, Andropogon, Paspalum raginatum, S. L. Wood; Missouri Kev, 28-V1-51, Paspalum cuginatum, S. L. Wood; Key West, 5-1V-0.3, E. A. Schwarz. Texas: Victoria, 26-111, E. A. Schwarz. MEXICO: Durango: 16 km W El Salto, Vll-64, J. B. Thomas. Yucatán: Chichen-Itza, 30-VI-51, L. J. Stannard. PUERTO RICO: Aguadilla, 1-99, A. Busck; Villalba, 30-IV-40, Brysonima spicata, D. DeLeon. HAWAIIAN ISLANDS: Keawekapa, Mani, 17-1X-64, Bermuda grass.

Hosts.- Andropogon sp., Cynodon dactylon, and Paspalum vaginatum.

Biology.-All specimens for which a host is known were taken from fruiting stems of the above grasses.

Notes. - The above treatment was based on the holotypes of pubescens, subelongatus, and opacifrons, and on 26 other specimens.

## 26. Hypothenemus eruditus Westwood

Diagnosis. - This is the most common and widely distributed species in the genus. It is somewhat variable in certain characters (frons and elytral vestiture) and not always as easily recognized as other species. The frons is convex, usually with a short, narrow, median groove near the upper level of the eyes (groove occasionally replaced by a granule), with punctures obscure to conspicuous. The principal diagnostic characters are summarized in the above key.

Female.- Length $1.0-1.3 \mathrm{~mm}, 2.4-2.6$ times as long as wide; mature color black.

Frons convex, a slight, transverse impression immediately above epistoma; surface ru-gose-reticulate, punctures fine to moderately coarse, median line shining or not, usually with a small median groove (rarely replaced by a tubercle) at upper level of eyes; vestiture inconspicuous.

Pronotum 0.85-0.95 times as long as wide; widest on basal third, sides moderately arcuate, converging slightly anteriorly on basal two-thirds, rather broadly rounded in front; anterior margin armed by six teeth (may vary from four to eight), lateral ones smaller; summit slightly in front of middle, rather well developed; posterior areas obscurely rugosereticulate, punctures small, shallow, a few of them subgranulate particularly behind summit. Vestiture of coarse hair in asperate anterior area, fine hair and erect scales intermixed on posterior half.

Elytra 1.6 times as long as wide; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, punctures moderately large; interstriae almost smooth, as wide as striae, punctures fine, uniseriate, very finely, often obscurely subvulcanate. Declivity steep, convex; about as on disc except interstrial granules very slightly larger. Vestiture of rows of fine, short, strial hair, often supplemented by similar interstrial hair on disc, supplemental hair almost always present on declivity, and rows of erect interstrial scales; each scale as long as distance between rows and between scales within a row, each scale from three to five times as long as wide.

Male- Similar to female except length $0.7-0.8 \mathrm{~mm}, 2.2$ times as long as wide; eye reduced in size; funicle usually 3 -segmented, club smaller, more slender; one or more marginal teeth on pronotum absent; vestiture slightly longer, more slender.

Distribution.-S California, Texas, Michigan, and New Jersey south to Argentina; S Europe and Asia to Africa and Australia.

USA: Alabama, California, District of Columbia, Florida, Georgia, Illinois, Louisiana, Maryland, Michigan, Mississippi, New Hampshire, New Jersey, New York, North Carolina, Pennsylvania, South Carolina, Tennessee, Texas, Virginia, West Virginia. MEXICO: Chiapas, Colima, Jalisco, Michoacán, Nayarit, Oaxaca, Puebla, San Luis Potosí, Veracruz, Yucatán. CENTRAL AMERICA: Guatemala, Honduras, Costa Rica, Panama. OTHER AREAS: South America, Antilles Islands, Africa, Australia, Europe, Asia, Pacific islands.

Hosts.- Several hundred host species are known.

Biology.- The habits are adjusted to meet the requirements of the host material. This species is reported as breeding in the cover of a book, in the fruiting bodies of fungi, in the fruiting stalks of grass, in weeds, and in numerous other plants. The tunnels may be restricted to the central axis of pith, or they may be in the phloem and engrave the cambium as in other phloeophagous bark beetles.

Notes.- The above treatment was based on a syntype of eruditus, on the holotypes of bradfordi, flavosquamosus, nigricollis, pruni, rumseyi, asiminae, hamamelidis, tenuis, myrmidon, myristicae, lineatifrons, obscurus, sacchari, webbi, koebelei, mali, parvus, flavipes, punctifrons, nigripennis, ferrugineus, heathi, punctipennis, elongatus, evonymi, flavicollis,
pygmaeus, subconcentralis, unicolor, erythrinae, and subcylindricus, on lectotypes (where designated) or syntypes of aspericollis, insularis, basjoo, bicolor, juglandis, intersetosus, dubiosus, glabratus, and ealensis, and on paratypes of citri. I have not seen authentic specimens of germari, ehlersii, boieldieui, tuberculosus, rotroui, lezjavai, and glabratellus; they are listed here only because they have previously been placed in synonymy by the authors cited. In addition to the above type material, 894 other specimens were examined.

The large number of synonyms has resulted partly from diversity, partly from the inability of taxonomists to see the minute characters due to limitations of their optical equipment, partly from the inaccessibility of previously described material, and largely from a faulty host selection principle conceived by Hopkins. Almost no two series of this species taken from different localities are exactly alike in the sculpture of the frons; the variability of other characters is insignificant by comparison. The beetles evidently reproduce either by arrhenotokic parthenogenesis and/or from sibling matings, thus reducing the genetic variability in a series or in a local population derived from one female. The resulting uniformity of characters seen in material from one locality contrasted with similar uniformity of a slightly different type at another has been difficult to interpret without knowledge of the genetics of this species. Until more is known these minor variants should be grouped.

Cosmoderes schwarzi Hopkins is known only from the balsam mount of one antenna. The funicle is 4 -segmented, not 3 -segmented as described, as can be seen in Hopkins' illustration and on the slide. In view of Hopkins' other taxonomic work and the form of the antenna of the type, it is almost certain that schwarzi is another synonym of eruditus.

## 27. Hypothenemus gossypii (Hopkins)

Fig. 194
Stephanoderes gossypii Hopkins. 1915, U.S. Dept. Agric. Rept. 99:25 (Holotype, female; Cayamas, Cuba; U.S. Nat. Mus., 7557)

Hypothcnemus beameri Wood, 1954, Univ. Kansas Sci. Bull. 36(2): 1056 (Holotype, female; Homestead, Florida; Snow Ent. Mhs.. Univ. Kansas); Wood. 1972. Great Basin Nat. 32:48. Synonymy

Diagnosis.- This species is distinguished from eruditus Westwood by the differently sculptured frons, by the widely separated median pair of teeth on the anterior pronotal margin, and by the very slender interstrial scales.

Female.- Length 1.2-1.4 mm, 2.6 times as long as wide; color black.

Frons below upper level of eyes shallowly, transversely impressed; median area above upper level of eyes with an indefinite elevation; surface finely rugose-reticulate, with coarse, deep, close punctures, median line smooth and shining on lower half; vestiture inconspicuous.

Pronotum 1.03 times as long as wide; about as in eruditus except anterior margin more broadly rounded; median pair of teeth on anterior margin widely separated; reticulation in lateral areas less distinct.

Elytra as in eruditus except interstrial scales more slender, each six to eight times as long as wide.

Male.-Similar to female except $0.75-0.95 \mathrm{~mm}, 2.4$ times as long as wide; eye reduced in size; funicle usually 3 -segmented, club smaller, more slender; one or more marginal teeth on pronotum absent; pubescence slightly longer.

Distribution.-S Florida, Cuba, and Hidalgo.
U'SA: Florida: Everglades N.P., 6-VII-51, Iehthyomethia communis, S. L. Wood: Homestead, 22-V1-51, Cappris bifolia, Annona, Bidens pilosa, Mangifera indica, Parmentiera edulis, Tectona grandis, S. L. Wood; Key Largo, 25-V1-51, Cajanus cajon, Waltheria americana, S. L. Wood; Key West, 3-V1I-51, Sida rhombifolia, S. L. Wood; Long Key, 27-VI-5l, Ica imbricata, S. L. Wood: Matecumbe Key, 28-VI-51, Poinsettia heterophylla, S. L. Wood; Plantation Key, 28-VI-51, Persea americana, S. L. Wood. CUBA: Cayamas, 7-I, Cossypium, E. A. Schwarz. MEXICO: Hidalgo: 25 km N Ixmiquilpan, 10-VII-67, 1900 m . No. 191, Nolena leaf bases. S. L. Wood. OTHER AREAS: Cuba.

Biology. - Apparently as in eruditus.
Notes. - The above treatment was based on the holotypes of gossypii and beameri and on 45 other specimens.

## 28. Hypothenemus distinctus Wood Fig. 194

Hypothenemus distinctus Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1065 (Holotype, female; Union, Missouri; Snow Ent. Mus., Univ. Kansas).

Diagnosis.- This species is distinguished from all other American Hypothenemus by the narrowly produced anterior margin of the pronotum that is armed by four basally contiguous teeth, by the small, slender, shining body form, and by the widely spaced interstrial scales.

Female.-Length $0.9 \mathrm{~mm}, 2.5$ times as long as wide; color dark brown.

Frons convex, a slight transverse impression above epistoma; median line impressed from upper level of eyes one-fourth distance to epistoma; surface coarsely reticulate, punctures fine, inconspicuous, sparse; vestiture inconspicuous.

Pronotum 0.97 times as long as wide; sides on basal half subparallel, weakly arcuate; anterior margin narrowly produced on median fourth and armed by four closely set teeth, median pair slightly larger; posterior area obscurely rugose-reticulate behind summit, smooth elsewhere, with sparse, fine, shallow punctures, a few of them subgranulate. Vestiture of coarse hair in asperate area, of fine hair and slender scales on posterior half.

Elytra as in eruditus, with strial punctures slightly larger, interstrial granules distinctly larger; supplemental interstrial hairlike setae absent; interstrial scales shorter, much more widely spaced within a row (about twice length of a scale), each scale about three times as long as wide.

Distribution.- Missouri.
USA: Missouri: Union, 26-VI-5I, Rhus aromatica, S. L. Wood.

Host.- Rhus aromatica.
Biology.- The type series was removed from the cambium region in a small, broken twig.

Notes. - The above treatment was based on the holotype and one paratype. One other specimen of unknown origin was examined.

## 29. Hypothencmus miles (LeConte) Fig. 194

Cryphalus miles LeConte, 1878. Proc. Amer. Philos. Soc. 17:433 (2 syutypes; Tampa, Florida; one syntype missing from pin at Mus. Comp. Zool., second syntype possibly at U.S. Nat. Mus.)
Diagnosis.- This species is allied to distinctus Wood, but it is distinguished by the strongly, narrowly produced, hornlike, median, anterior margin of the pronotum, with
no other marginal teeth, by the very small, obscure, strial punctures, by the smaller interstrial granules, and by the broader interstrial scales.

Female.- Length $1.05-1.15 \mathrm{~mm}, 2.7$ times as long as wide; color almost black.

Frons as in distinctus except median impression usually replaced by a feeble elevation. Pronotum as in distinctus except anterior margin narrowly, strongly produced into a fingerlike process, anterior margin not armed by other teeth; posterior and lateral areas reticulate.

Elytra as in distinctus except strial punctures minute, interstriae much wider than striae; interstrial granules small to obscure; interstrial scales broader, each about twice as long as wide.

Distribution.-Georgia to Florida.
USA: Florida: Tampa, I5-VII. Georgia: St. Catherine Island, 19-IV, Hubbard and Schwarz.

Notes.- The syntype and also the second specimen in the LeConte Collection, from Columbus, Texas, were missing from their pins in 1952. A specimen recovered from the bottom of the unit tray was of distinctus; presumably it was the Columbus specimen. The other syntype evidently was returned to the U.S. National Museum, where several other Tampa specimens are deposited. The above treatment was based on the U.S. National Museum series of eight specimens.

## 30. Hypothenemus teretis Wood

Hypothenemus teretis Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. I5(3):35 (Holotype, female; Finca La Lola, Limón, Costa Rica; Wood Coll.)
Diagnosis.- This is the only American Hypothenemus with erect, scalelike interstrial bristles on the disc, but with these setae reduced to minute, slender hair on the declivity. In this respect it resembles the unrelated dipterocarpi Hopkins from the western Pacific Islands.

Female.- Length $1.0-1.2 \mathrm{~mm}, 2.2$ times as long as wide; color almost black.

Frons moderately, transversely impressed on lower two-thirds, convex above, with low, distinct elevation at upper level of eyes occupying median sixth; surface rugose-reticulate, punctures moderately coarse, shallow; vestiture inconspicuous.

Pronotum 0.94 times as long as wide; as in eruditus.

Elytra 1.5 times as long as wide; outline as in eruditus; striae not impressed, punctures fine, very shallow, seen with difficulty; interstriae subrugose, at least twice as wide as striae, punctures fine, obscure, uniseriate. Declivity rather steep, convex; striae weakly impressed, otherwise as on disc. Vestiture of rows of very minute strial hair, and rows of interstrial setae; interstrial setae on disc scalelike, each about four to six times as long as wide, these setae on posterior half of elytra represented by shorter, fine, slender, hairlike setae resembling strial setae.

Distribution.-Costa Rica and Venezuela.

COSTA RICA: Playón, San José, 22-II-64, 50 m , No. 449. Canacalia cillosa, S. L. Wood; Beverley, Limón, 26-VIII-63, 7 m , No. 154, vine, S. L. Wood; Finca La Lola, 10-I-63, Theobroma cacao, J. L. Saunders. VENEZUELA: 5 km W' El Pino, Zulia, 20-X-69, 10 m , No. 139 , Inga, S. L. Wood. 20 km SW El Vigia, 22-X-69. 100 m . No. 81, Cecropia petiole, S. L. Wood; 9 km S Barrancas, Barinas, 5-NI-69, 150 m , No. 101, Seriania: S. L. Wood: 30 km E Palmar, Bolivar, 12-VI-70, 200 m . No. 575. Sterculia pruriens, S. L. Wood.

Hosts.-Canacalis villosa, Cecropia sp., Inga sp., Serjania sp., and Sterculia pruriens.

Biology.- Specimens were taken from recently cut or broken vines, small lianas, and twigs. Only small numbers of specimens were taken on each occasion the species was collected, and these were always mixed with other species of Hypothenemus. It is presumed the habits are much as in eruditus.

Notes.- The above treatment was based on the type series of 18 specimens.

## 31. Hypothenemus parallelus (Hopkins)

Stephanoderes parallelus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:25 (Holotype, female; Tampico, Mexico; U.S. Nat. Mus., 7556).
Diagnosis.- This probably is not a valid species. It is distinguishable from eruditus Westwood only by the presence of a small, low, transverse, median, frontal tubercle at the upper level of the eyes.

Female.- Length $1.0-1.1 \mathrm{~mm}, 2.6$ times as long as wide; color almost black.

As indicated in the above diagnosis, the frontal tubercle provides the only means of distinguishing this form from eruditus.

Distribution.-Tamaulipas, Colima, and the Hawaiian lslands.

MEXICO: Colima: 24 km W Armeria, $30-\mathrm{VI}-65,30 \mathrm{~m}$. No. 153. tree branch, S. L. Wood. Tamaulipas: Tampico, 26-XII, E. A. Schwarz. HAWAIIAN ISLANDS: Honolulu, Oahu, 24-ViI-64, L. glauca, C. Hammond: Moanalua, Oahu, 7-IN-50. E. J. Ford.

Notes.- The above treatment was based on the holotype of parallelus, on 2 specimens from Colima, and on 11 specimens from Hawaii.

Some specimens of eruditus have a very small median granule or tubercle at the upper level of the eyes strongly resembling the distinctly larger, transverse tubercle of parallelus. In the Hawaiian specimens there is a feeble transverse impression below this tubercle. Until future collecting demonstrates complete intergradation between these forms, it appears best to maintain parallelus as a distinct species.

## 32. Hypothenemus cylindricus (Hopkins)

Stcplumoderes cylindricus Hophins, 1915. U.S. Dept. Agric. Rept. 99:25 (Holotype, female; Trece Aguas, Alta Verapaz, Guatemala; U.S. Nat. Mus., 7564)

Hypothenemus pallidus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:18 Holotype, female: Mt. Coffee. Liberia; U.S. Nat. Mus., 7590); Wood, 1972, Great Basin Nat. 32:45. Synonymy
Stephanoderes transatlanticus Eggers, 1941, Arb. Morph. Tax. Ent. Berlin-Dahlem 8:99 (Holotype, female: Trois Rivières, Guadeloupe; Paris Mus.); Wood, 1972, Great Basin Nat. 32:45. Synonymy
Hypothenemus guadeloupensis Schedl. 1951, Dusenia 2:98 (Syntypes, female; Guadeloupe; Schedl Coll.); Wood, 1976. Great Basin Nat. 36:348. Synonymy
Diagnosis.- This species is distinguished from eruditus Westwood only by characters of the frons. The frons is rather abruptly impressed on the median sixth or less at the upper level of the eyes; the shallow impression continues on the median third to the epistoma. The impression is stronger than in parallelus, with its upper limits usually not resembling a tubercle.

Female.- Length $1.1-1.3 \mathrm{~mm}, 2.7$ times as long as wide; color almost black.

As indicated in the above diagnosis, the frontal impression is the only means of distinguishing this form from parallelus.

Distribution.- Veracruz to Colombia and Venezuela; Africa.

MEXICO: Veracruz: 5 km w Jaltipan, 25-V1-67, 50 m , Bamboo, S. L. Wood. GUATEMALA: Rodeo, Esquintla, 4-VI-64, 150 m , No. 676, tree branch, S. L. Wood; Trece Aguas, Alta Verapaz. 15-IV, Cacao, Barber and Schwarz. HONDURAS: Zamorano, Morazán, 18-IV-64, 700 m , No. 560, Dioclea megacarpa, S. L. Wood; La Lina, Cortez, 5-V-64, 200 m , Cayaponia microdonta, S. L. Wood. COSTA RICA: Río Tempisque, Guanacaste, 25-III-64, 15 m, No. 501, Ficus, S. L. Wood; Río Damitas in Dota Mits., San José, 18-II-64, 250 m , No. 436, tree seedling, S. L. Wood; San Isidro del General, San José, 13-XII-63, 1000 m , No. 309, Daphnopsis seibertii, S. L. Wood: Playón, Puntarenas, 22-II-64, 50 m . No. 449, Canatalia cillosa, S. L. Wood; Dominical, Puntarenas, 9-XII-6.3, 3 m, No. 297, tree branch, S. L. Wood; Volcán, Puntarenas, 11-XII-63, 500 m , No. 304, tree branch, S. L. Wood. PANAMA: Barro Colorado Island, Canal Zone, 27-X11-63. 70 m , No. 347, tree branch, S. L. Wood; Ft. Clayton, 22-XII-6.3, 30 m , No. 318, Serjania, S. L. Wood; Madden Forest, Canal Zone, 2-I-64, 70 m , No. 306, tree branch. S. L. Wood. OTHER COUNTRIES: Colombia, Venezuela, Guadeloupe, Liberia.

Notes. - The above treatment was based on the holotypes of cylindricus, pallidus, and transatlanticus, on a syntype of guadeloupensis, and on 59 other specimens.

The specimens from Mexico and northern Central America are distinguished with difficulty from parallelus only by the slightly stronger and more extensive impression on the lower frons. Those from Costa Rica southward usually have the impression stronger, almost concave on a narrow area. The frontal structure of parallelus is intermediate between this species and eruditus, but the transition, based on available material is neither gradual nor orderly.

## 33. Hypothenemus suspectus Wood

Hypothenemus suspectus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):22 (Holotype, female; Pandora, Limón, Costa Rica; Wood Coll.)
Dagnosis.- This species is distinguished from the closely allied cylindricus Hopkins by the less extensive frontal impression, and by the much more slender interstrial scales. It could easily be confused with areccae (Hornung), but it is smaller, and the frontal impression is much less extensive and more shallow.

Female.- Length 1.1-1.3 mm, 2.4 times as long as wide; color almost black.

Frons as in cylindricus except lower frons shallowly, transversely impressed, not con-
cave. Pronotum and elytra as in cylindricus except interstrial supplemental hairlike setae in ground vestiture more abundant on and near declivity, and erect interstrial scales much more slender, each scale about eight times as long as wide.

Distribution.- Costa Rica to Panama, and Venezuela.

MEXICO: Nayarit: 8 km E San Blas, 12-VII-65, tree branch, S. L. Wood. COSTA RICA: Rincón de Osa, Puntarenas, I1-VIII-66, 30 m , No. 58 . Ceeropia petiole, S. L. Wood; Cañas, Guanacaste, 3-I1-67, Cecropia petiole; Pandora, Limón. 23 -VIII-63, 50 m, No. 148, cucurbit vine, No. 149, tree branch, S. L. Wood; Finca La Lola, Limón, 10-I-63, Theobroma cacao, J. L. Saunders. PANAMA: 13 km S El Hato del Volcán, Chiriqu, 7-1-64, 1000 m , No. 371, tree seedlings, S. L. Wood: Barro Colorado 1 sland, I-V111-41. VENEZUELA: 32 km SW El Vigía, Merida, $10-\mathrm{X} 11-69,50 \mathrm{~m}$, No. 188 , vine, S. L. Wood: 17 km SE Mirí, Barinas. 17-XIl-69, 150 m , No. 196, Albizzia caribaea, S. L. Wood; 3 km NE Creole, Barinas, I8-X11-69. $150 \mathrm{~m}, \mathrm{No} .203$, Inga, S. L. Wood.

Hosts.- Albiz~ia caribaca, Cecropia sp., Inga sp., Theobroma cacao, etc.

Bıology. - The habits are as in eruditus.
Notes.- The above treatment was based on the type series of 17 specimens.

## 34. Hypothenemus areccae (Hornung)

Bostrichus areccae Hornung, 1842, Stett. Ent. Zeit. 3:117 (Lectotype, female; in Betel palm nuts presumably of East Indian origin: Berlin Zool. Mus., designated by Wood. 1974, Great Basin Nat. 34:282)
Hypothenemus cafer Blandford, 1896, Ann. Soc. Ent. Belgique 40:241 (Syntypes; Noumea, New Caledonia); Wood, 1974. Great Basin Nat. 34:282. Synonymy
Stephanoderes fungicola Eggers, 1908, Ent. Blätt. 4:216 (Holotype, female; Java; Fiori Coll.); Eggers, 1929, W'iener Ent. Zeit. 46:52. Synonymy
Stephanoderes polyphagus Eggers. 1924, Ent. Blätt. 20:104 (Syntypes; Congo: Tervuren Mus.); Wood, 1972, Great Basin Nat. 32:52. Synonymy
Stephanoderes hispidus Eggers, 1925, Ent. Odd. Narod. Mus. Prage 3:156 (2 syntypes, Birma and India orient., both probably from Tenasserim, both lost with Hamburg Mus.); Wood, 1960. Insects of Micronesia 18(1):41. Synonymy
Hypothenemus heterolepsis Costa Lima, 1928. Suppl. Mem. Inst. Oswaldo Cruz 4:117 (Syntypes) (Article not seen); Wood, 1972, Great Basin Nat. 32:52. Synonymy
Hypothenemus capitalis Beeson, 1935, Bull. B.P. Bishop Mus. 142:102 (Lectotype, female; Hakehetau Valley, Uapou, Marquesas 1sl.: Bishop Mus., 1109, present designation); Wood, 1960, Insects of Micronesia 18(1):41. Synonymy

Hypothenemus eupolyphagus Beeson, 1940, Occas. Pap. Bishop Mus. 15(18): 193 (Holotype, female; Dehra Dun. India: Beeson Coll. at Dehra Dun); Wood, 1960, lasects of Micronesia 18(1):41. Synonymy
Stephanoderes subrestitus Eggers, 1940, Rev. Zool. Bot. Afr. 33:232 (Holotype, female; Mosolo Kwenge, Kwango, Congo; Tervuren Mus.); Wood, 1972, Great Basin Nat. 32:52. Synonymy
Stephamoderes martiniquensis Eggers, 1941, Arb. Morph. Tax. Ent. Berlin-Dahlem 8:99 (Holotype, female; St. Pierre, Martinique: U.S. Nat. Mus., 60156); Wood, 1972, Great Basin Nat. 32:52. Synonymy Hypothenemus oahuensis SchedI, 1941, Proc. Hawaiian Ent. Soc. 11:110 (Syntypes, female; Punaluu, Oahn, Hawaiian lslands; Bishop Mus.); Wood, 1960, Insects of Micronesia 18(1):41. Synonymy
Diagnosis.- This species is distinguished from columbi Hopkins by the larger average size, by the more slender interstrial scales, and by the more broadly concave frons, with upper limits of concavity rather abrupt but not carinate. From suspectus Wood it is distinguished by the much more broadly, more deeply impressed frons, with the abrupt upper margin occupying at least the median two-thirds of the area between the eyes.

Female. - Length 1.2-1.4 mm, 2.4 times as long as wide; color light to very dark yellowish brown.

Frons rather strongly, broadly, transversely impressed to upper level of eyes, upper margin of impression abrupt, obtuse, not actually carinate, on more than median two-thirds of area between eyes; surface of impressed area smooth, shining, finely, deeply, closely punctured, upper area reticulate to very slightly subrugulose; vestiture inconspicuous.

Pronotum as in cruditus Westwood, but surface of posterior areas tending to be smoother, shining.

Elytra as in eruditus, with strial and interstrial punctures finer, granules entirely absent; hairlike ground vestiture slightly more abundant; interstrial scales slightly longer, more slender, each scale six or more times as long as wide.

Distribution.-S Florida, Brazil, Pacific Islands to India, and Africa.

USA: Florida: West Palm Beach, 19-V-60, Delonix regia recently imported from the Bahama Islands. OTHER COUNTRIES: Brazil, Puerto Rico, Virgin lslands, Martinique, Hawaiian Islands, Micronesia, Philippine Islands, New Caledonia, Indonesia, Ceylon, India, Ghana, Congo, Liberia.

Hosts. - Many dozens of hosts have been recorded from the Indo-Malayan area and Africa.

Biology.- Apparently as variable as in eruditus, but more commonly found in seeds and fruits.

Notes.- The above treatment was based on the lectotype of areccae, on the holotype of martiniquensis, on syntypes of cafer, polyphagus, heterolepsis, capitalis, and oahuensis, on Eggers homotype of fungicola, and on paratypes or cotypes of hispidus, eupolyphagus, and subvestitus, and on 266 other specimens.

From the 2 female syntypes of areccae in the Berlin Zoologisches Museum, the second specimen was designated as the lectotype of Bostrichus areccae Hornung. Presumably, because Eggers was not familiar with the frontal characters in this species group, he designated specimens of both areccae and eruditus Westwood as having been compared to the "type." This error led to a great deal of confusion involving this species. Four cotypes of Cryphalus basjoo Niisima and 10 specimens of Stephanodercs fungicola Eggers in the Eggers Collection are of this species. The first specimen in the type series of capitalis Beeson, a female from Hakehetau Valley Uapou, is labeled as the type of Beeson's species, although it has never been so designated. I here designate that specimen as the lectotype of capitalis. A cotype of Stephanoderes bambesanus Eggers is of this species; the type was not located to check the suspected synonymy.

## 35. Hypothenemus columbi Hopkins

Fig. 194
Hypothenemus columbi Hopkins, 1915, U.S. Dept. Agric. Rept. 99:18 (Holotype, female; Columbus, Texas; U.S. Nat. Mus., 7361)
Hypothenemus abdominalis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:18 (Holotype, female; Cayamas, Cuba; U.S. Nat. Mus., 7576); Wood, 1954, Uniw. Kansas Sci. Bull. 36(2):1062. Synonymy
Hypothenemus rufopalliatus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:18 (Holotype, female; Charleston, South Carolina; U.S. Nat. Mus., 7577); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1062. Synonymy
Hypothenemus brunneipennis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:18 (Holotype, female; Cayamas, Cuba; U.S. Nat. Mus., 7578); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1062. Synonymy

Hypothenemus amplipennis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:19 (Holotype, female; Cayamas, Cuba; U.S. Nat. Mus., 7579); Wood, 1954, Univ. Kansas Sci. Bull. 36(2):1062. Synonymy
Dtagnosis.- This species is distinguished from the closely allied cylindricus Hopkins by the much deeper frontal impression and the transversely carinate frontal elevation, and by the broader elytral scales. It is much more likely to be confused with areccae (Hornung), from which it differs by the smaller size, by the less extensive frontal impression, by the more strongly elevated, acute, transverse frontal carina that occupies less than the median third, and by the shorter, broader, interstrial scales.

Female. - Length $1.0-1.2 \mathrm{~mm}, 2.6$ times as long as wide; color dark brown.

Frons strongly, transversely impressed from epistomal margin to two-thirds distance to upper level of eyes, upper margin of impressed area on median fourth of area between eyes strongly, subacutely elevated as a short, transverse carina; surface of impressed area smooth, shining in median area, finely punctured laterally, upper area above carina convex, rugose-reticulate, rather coarsely, deeply punctured; vestiture inconspicuous.

Pronotum as in eruditus, with teeth on anterior margin more widely spaced; surface of lateral areas subreticulate to densely marked by minute points, sublateral areas more nearly shining.

Elytra 1.7 times as long as wide; as in eruditus, except strial punctures usually very slightly larger and deeper; interstrial scales slightly more than half as long as distance between rows, spaced within a row by distances greater than length of a scale, each scale two to (rarely) four times as long as wide.

Male.-Similar to female except 0.8 mm , 2.4 times as long as wide; eye reduced in size; funicle usually 3 -segmented, club reduced in size; one or more marginal teeth on pronotum usually absent; pubescence longer, more slender.

Distribution.- Texas and Florida to Colombia and Venezuela.

USA: Florida: Everglades N.P., Homestead, Perrine. Georgia: Richmond Hill. Louisiana: Creole, New Orleans. Mississippi: Nicholson, Picayune, Poplarville. South Carolina: Burton, Charleston, Mt. Pleasant. Texas: Brownsville, Columbus. Victoria. MEXICO: Colima: 3 km E and 24 km W Armeria. Nayarit: Los Corchos, 32 km N Tepic. Sinaloa: 8 km N Mazatlán.

Veracruz: 8 km S San Andres Tuxtla. COSTA RICA: Finca Taboga near Cañas. PANAMA: Canal Zone. OTHER AREAS: Bahamas Islands (Nassau), Cuba, Colombia, Venezuela.

Hosts.- Bauhinia alba, Citrus aumatifolia, Ficus spp., Ichthyomethia communis, Morus rubra, Quercus spp., Salix sp., Serjania sp.

Biology.- Evidently as in eruditus.
Notes. - The above treatment was based on the holotypes of columbi, abdominalis, rufopalliatus, brunneipennis, and amplipennis, and on 43 other specimens.

## 36. Hypothenemus africanus (Hopkins)

Stephanoderes africanus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:30 (Holotype, female; Capetown, South Africa; U.S. Nat. Mus., 7542)
Diagnosis.- This species is distinguished from setosus Eichhoff by the slightly larger size, by the less strongly impressed, less extensive frontal concavity, by the confused discal interstrial punctures, and by the shorter, closer, much broader interstrial scales.

Female.- Length I.7-1.9 mm, 2.3 times as long as wide; color brown.

Frons as in setosus except less strongly impressed, concavity on upper half of impressed area only (variable). Pronotum as in setosus, with six to eight teeth on anterior margin; posterolateral areas smooth and shining.

Elytra as in setosus, strial punctures usually more distinctly impressed, interstrial punctures on disc fine, confused; interstrial scales two-thirds as long as distance between rows, spaced within a row by distances less than length of a scale, each scale two to three times as long as wide.

Distribution.- Alabama and Louisiana to Venezuela and Brazil, Indonesia, Malaya, and Africa.

USA: Alabama: Mobile, 19-1-46, Delonix pods (probably intercepted in port). Louisiana: New Orleans, 19-VI-33, intercepted in bean pods from Honduras. COSTA RICA: 1940, Nevermann. JAMAICA: 13-1X-35, Poinciana pods, lot no. 35-19295. BAHAMA ISLANDS: Nassal1, 21-1-47, Morus. DOMINICAN REPUBLIC: Santo Domingo. PUERTO RICO: 29-[-47, pods. VENEZUELA: 3 km E Lagunillas, Merida, $12-\mathrm{I}-70,1000 \mathrm{~m}$, No. 237, Mimosa twig, S. L. Wood. OTHER COUNTRIES: Brazil, Java, Malaya, South Africa.

Biology.- Evidently variable; fruiting pods and twigs of trees were infested.

Notes.- The above treatment was based on the holotype of africanus and on 54 other specimens.

## 37. Hypothenemus setosus (Eichhoff)

Hypoborus (?) setosus Eichhoff, 1868, Berhiner Ent. Zeitschr. 11:391 (Syntypes; Guadeloupe: one syntype in U.S. Nat. Mus., others lost in Hamburg Mus.)
Stephanoderes obscurus Eichhoff, 1872, (nec Ferrari, 1867). Berliner Ent. Zeitschr. 15:133 (Holotype, female; Antilles; Institut Royal des Sciences Naturelles, Brussels): Wood, 1975. Great Basin Nat. 35:39.3. Synonymy
Stephanoderes depressus Eichhoff. 1578, Mém. Soc. Roy. Sci. Liége (2)8: 155 (Replacement name for obscurus Eichhoff)
Stephanoderes congonus Hagedorn, 1912, Rev. Zool. Afr. 1:3:37 (Lectotype, female; Eala, Congo, Tervuren Mus., designated by Wood, 1975, Great Basin Nat. 35:39:3). Synonymy
Diagnosis.- This species is distinguished from jacanus (Eggers) by the details of head sculpture mentioned below, by the presence of six to eight serrations on the anterior margin of the pronotum, by the smaller, more numerous pronotal asperities, and by the more slender body form.

Female.- Length $1.6-1.7 \mathrm{~mm}, 2.4$ times as long as wide; color brown.

Head as in javanus except punctures on frons slightly larger and more abundant; areas above impression coarsely reticulate.

Pronotum 0.95 times as long as wide; as in javanus except anterior slope armed by more than 25 small asperities: anterior margin armed by six to eight serrations.

Elytra 1.5 times as long as wide; as in javanus.

Male.- Similar to female except sexes differing as in javanus.

Distribution.- Florida and Chiapas to Brazil, and Africa.

USA: Florida: Miami. MEXICO: Chiapas: Cotaxtla. HONDURAS: Zamorano. COSTA RICA: Playón in San José, Finca Gromaco on Río Coto Brus in Puntarenas, Finca La Lola in Limón. PANAMA: Canal Zone: Ft. Clayton, Gatum Dam, Paraiso. OTHER AREAS: Brazil, Colombia, Guadeloupe, Haiti, Puerto Rico, Venezuela, Congo, Cameroon.

Hosts.- Acacia pennatula, Cecropia sp., Theobroma cacao.

Biology.- This species occurs in fruiting bodies, Cecropia petioles, and twigs of a wide variety of hosts.

Notes.- The above treatment was based on the syntype of setosus, on the holotype of obscurus, on four female syntypes of congonus, and on 92 other specimens. The original description of congonus obviously was based on a syntypic series; however, a severely damaged specimen in the Tervuren Museum is labeled "Holotypus." ln view of the syntypic description, the severely damaged "Holotypus," the fact that all four syntypes bear identical data labels, and that a lectotype has not previously been designated, I here designate the third syntype as the lectotype of Stephanoderes congonus Hagedorn.

## 38. Hypothenemus javanus (Eggers)

 Fig. 194Stephanoderes jaramus Eggers. 1908. Ent. Blätt. 4:215 (Lectotype, female: Java U.S. Nat. Mus. 60124, designated by Anderson and Anderson, 1971, Smithsonian Contrib. Zool. 94:16); Wood, 1975, Great Basin Nat. 35:393. Status discussed
Stephanoderes obesus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:30 (Holotype, female; Cayamas, Cuba; U.S. Nat. Mus., 7543); Wood, 1957. Canadian Ent. 89:402. Synonymy
Stephanoderes philippinensis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:31 (Holotype, female; Angat. Philippine 1slands; U.S. Nat. Mus., 7544); Wood, 1957. Canadian Ent. 89:402. Synonymy

Stcphanoderes bananensis Eggers, 1922, Ent. Blätt. 18:167 (2 syntypes: Banana, Congo; Eggers Coll.); Wood, 1972, Great Basin Nat. 32:5I. Synonymy
Stephanoderes kalshoteni Schedl, 1939, Tijdschr. Ent. 82:35 (Syntypes: Pasoeroean, Java; Buitenzorg Mus.); Wood, 1972, Great Basin Nat. 32:51. Synonymy
Stephanoderes subagnatus Eggers, 1940, Rev. Zool. Bot. Afr. 33:101 (Holotype, female; Eala, Congo; Tervuren Mus.); Wood, 1972, Great Basin Nat. 32:51. Synonymy
Stephanoderes pistor Schedl, 1951, Dusenia 2:102 (2 syntypes; Havana, Cuba; Schedl Coll.); Wood, 1976, Great Basin Nat. 36:348. Synonymy
Stephanoderes prosper Schedl, 1951. Dusenia 2:103 (Holotype, female; Guadeloupe: Schedl Coll.); Wood, 1976, Great Basin Nat. 36:348. Synonymy
Diagnosis.- This species is distinguished from brunneus Hopkins by the slightly larger size, by the more slender, longer interstrial scales, and by the smoother, more closely punctured posterolateral areas of the pronotum.

Female.- Length $1.4-1.7 \mathrm{~mm}, 2.2$ times as long as wide; color brown.

Frons transversely, subconcavely impressed on median two-thirds from epistoma to
rather well above upper level of eyes, upper margin of impressed area rather sharply defined but not carinate; surface of concave area smooth, shining, with fine punctures particularly in lateral areas, upper areas above impression minutely, longitudinally etched, punctures rather fine, deep, close; scanty vestiture hairlike, confined to impressed area.

Pronotum 0.9 times as long as wide; widest one-third length from base, sides on basal half weakly arcuate, broadly rounded in front; anterior margin armed by two to four teeth, median pair often absent or at least reduced in size; 12-18 coarse asperities on anterior slope; summit moderately high; posterolateral areas almost smooth, shining, with moderately abundant, small, shallow, sharply impressed punctures. Vestiture of coarse hair in asperate area, of fine, short hair intermixed with slightly longer, slender scales on posterior half.

Elytra 1.3 times as long as wide; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, punctures fine, shallow; interstriae almost smooth, about twice as wide as striae, punctures very fine, uniseriate, not at all granulate. Declivity convex, moderately steep; strial punctures obsolete before apex. Vestiture of rows of fine, rather short strial hair, supplemented by some similar interstrial hair, and rows of erect interstrial scales; each scale equal in length to distance between rows and between scales within a row, each about six to eight times as long as wide.

Male.-Similar to female except 1.4 mm or less, 2.2 times as long as wide; eye reduced in size; funicle usually 3 -segmented; teeth on anterior margin of pronotum absent or abnormal; pubescence longer.

Distribution. - S Florida, Cuba, and Jalisco; Indonesia, Philippines, Africa.

USA: Florida: Coconut Grove, Delray Beach, Dade City, Everglades N.P., Homestead, Key Largo, Miami, Paradise Key, Perrine, Royal Palm Hammock St. Pk. MEXICO: Jalisco: La Huerta. OTHER AREAS: Philippine lslands, Java, Ghana, Congo, Cameroon.

Hosts.- Bauhinia alba, Conocarpus erecta, Eleagnus pungens fruitlandi, Ficus aurea, Hevea brasiliensis, Leucania glauca, Mangifera indica, Ochroma sp., Ocotea catesbiana, Persea borbonia, Rheedia sp., Rhizophora mangle, Trema floridana, Vitis sp.

Biology.- Essentially as in dissimilis.
Notes. - The above treatment was based on the lectotype of javanus, on the holotypes of obesus, philippinensis, and subagnatus, on syntypes of bananensis, kalshoveni, and pistor, and on 118 other specimens.

This species evidently was introduced to other areas from Africa.

## 39. Hypothenemus brunneus (Hopkins)

Fig. 19.4
Stephanoderes brunneus Hopkins, 1915, U.S. Dept. Agric. Rept. 99:31 (Holotype, female; Brownsville, Texas; U.S. Nat. Mus., 7545)
Stephanoderes frontalis Hopkins, 1915, U.S. Dept. Agric. Rept. 99:31 (Holotype, female; Brownsville, Texas: U.S. Nat. Mus., 7384): Wood. 1954, Univ. Kansas Sci. Bull. 36(2):1031. Synonymy
Hypothenemus cryphalomorphus Schedl, 1939. Proc. Roy. Ent. Soc. London 8(1):14 (Holotype, female; Trinidad, British West Indies; British Mus. Nat. Hist.); Wood, 1977, Great Basin Nat. 37:208. Synonymy
Stephanoderes bituberculatus Eggers, 1940, Arb. Morph. Taxon. Ent. Berlin-Dahlem 7:126 (Holotype, female; Env. de Trois Rivières, Guadeloupe; Paris Mus.); Wood, 1977, Great Basin Nat. 37:208. Synonymy
Diagnosis.- This species is distinguished from javanus (Eggers) by the slightly smaller size, by the shorter, stouter interstrial bristles, and by the reticulate posterolateral areas of the prontum, with fewer subgranulate punctures.

Female.- Length $1.3-1.45 \mathrm{~mm}, 2.3$ times as long as wide; color brown.

Frons as in javanus except less strongly concave, upper margin of impression acutely, strongly carinate. Pronotum as in javanus except posterolateral areas reticulate, subshining, punctures minute, less numerous, some of them usually finely granulate. Elytra as in javanus, strial punctures possibly smaller; discal surface minutely subrugose in most specimens; interstrial scales two-thirds as long as in javanus, each about four times as long as wide.

Male.- As in female except sexes differing as in javanus.

Distribution.-S Texas and Florida to Panama.
USA: Alabama: Mobile. Florida: Biscayne Bay, Delray Beach, Everglades N.P., Homestead, Key Largo, Key West, Matecumbe Key, Miami, Sugar Loaf Key. Texas: Brownsville, Port isabel, Southmost, Thayer. MEXICO: Colima: 3 km E Armeria, 53 km S Colima, 6 km S

Cihuatlán. Jalisco: 8 km S La Huerta. Nayarit: Los Corchos, 25 km NW Ixtlán, 8 km S Rosamorada, 8 and 27 km E San Blas. Oaxaca: 9 km W Zanatepec. Puebla: 13 km NW Acatlán. Sinaloa: Concha. Mazatlán. Sonora: "Sonora." Tamaulipas: Tampico. Veracruz: Cerro Gordo, 35 km SE Jalapa, 3 km S Rinconada, 24 km W Veracruz. Yucatán: Chichen-Itza. HONDURAS: La Ceiba. PANAMA: Taboga Island. OTHER AREAS: Bahama Islands, Cuba, Puerto Rico, Trinidad, Virgin Islands.

Hosts. - Acacia farnesiana, Albizzia labbekoides, Annona sp., Ardesia paniculata, Bauhinia grandiceps, Berria amonilla, Cajanus cajon, Canavalia sp., Celtis iguana, C. laevigata, Clematis sp., Condalia obtusifolia, Dalbergia ecastophyllum, Ficus sp., Galactia spiciformis, Gliricidia sepium, Grewia asiatica, Hovenia dulcis, Ichthyomethia communis, Leucania glauca, Lysiloma bahamensis, Mimosa sp., Ocotea catesbyana, Poinsettia heterophylla, Serjania sp., Trema floridana, Vachellia farnesiana.

Biology.- Essentially as in dissimilis.
Notes.- The above treatment was based on the holotypes of brunneus, frontalis, bituberculatus, and cryphalomorphus, and on 205 other specimens.

This species almost certainly was introduced from Africa or a neighboring area, but I have not yet seen African specimens. It differs so slightly from javanus that it is possible these two forms were introduced from two or more widely separated areas and appear as two species in the American fauna only because of intensive inbreeding resulting from arrhenotokic parthenogenesis.

## Genus CRyptocarenus Eggers

Cryptocarcnus Eggers. 1937. Rev. de Ent. 7:79 (Typespecies: Cryptocarenus diadematus Eggers, original designation)
Tachyderes Blackman, 1943, J. Washington Acad. Sci. 33:35 (Type-species: Tachyderes floridensis Blackman = Cryptocarcnus scriatus Eggers, original designation); Schedl, 1951, Dusenia 2:72. Synonymy
Diagnosis.- This genus is distinguished by the large, deeply emarginate, very coarsely faceted eyes, by the aseptate antennal club that has two procurved sutures marked only by setae, by the smooth, shining appearance, with virtually all vestiture obsolete (except some South American species), and by the strong, superficial resemblance to Pityophthorus.

Description.- Length, female 1.4-3.0 mm , males about one-third smaller, 2.6-2.7
times as long as wide; color yellowish or reddish brown to dark brown.

Sexually dimorphic, males reduced in size and slightly deformed. Female frons variously sculptured, vestiture inconspicuous. Eye very large, deeply emarginate; coarsely faceted. Antennal scape elongate; funicle 5 -segmented, club moderately small, oval, aseptate, sutures 1 and 2 weakly procurved, indicated only by rows of setae. Pronotum about as long as wide, basal and posterior three-fourths of lateral margins marked by a fine, raised line; summit moderately developed, asperities on anterior slope ather small, numerous, anterior margin armed by 8 to 14 teeth; posterior areas smooth, shining, finely punctured, vestiture sparse, hairlike. Elytra conservatively sculptured; striae not impressed, punctures fine; interstriae impunctate on disc, smooth, shining, minute points often present; declivity moderately steep, convex, a few interstrial punctures present; vestiture confined to declivity, consisting of sparse interstrial bristles, their apices usually flattened. Tibiae usually more slender than in Hypothenemus.

Distribution.- Texas and Florida to Argentina; one species introduced into Africa; 10 species are known.

Brology.-As in Hypothenemus, the males are dwarfed, rare, and flightless. Mating, when it occurs in the brood tunnels, usually is either between siblings or between mother and son. Adult females attack small cut or unthrifty stems less than $2-3 \mathrm{~cm}$ in diameter of lianas, shrubs, or trees. They enter the twig and construct an elongate, axial pith tunnel. Larvae extend the parental tunnel and usually do not excavate the hardy, woody tissues unless there is crowding.

Notes.- Due to the superficial resemblance of representatives of this genus to certain of the Pityophthorini, Schedl (1962) included this genus in the Pityophthorini, although the metepisternum is not covered by the elytra, the sutures on the posterior face of the antenna are strongly displaced, the costal margins near the elytral apex ascend significantly, and the males are dwarfed, rare, and do not participate in the construction of new galleries for the next generation.

## Key to the Species of Cryptocarenus

1. Frons at least weakly convex from epistoma to upper level of eyes ..... 2

- Frons moderately to rather strongly impressed or subconcave from epistoma to upper level of eyes ..... 4
2(1). Area from epistoma to upper level of eyes and from eye to eye uniformlysculptured, deeply punctured, punctures indistinctly oriented into obscure lon-gitudinal rows, sculpture changing abruptly at upper level of eyes; anteriormargin of pronotum armed by 10-14 teeth; Oaxaca to Panama, Venezuela,Brazil; 2.3-3.0 mm
- Frons more finely, rugosely sculptured from epistoma to well above eyes, either punctured or with rugosities obscurely aciculate; anterior margin of pronotum armed by 7-9 teeth; smaller3

3(2). Frons evenly convex, punctured from epistoma to above eyes, entirely devoid of rugosities, no indication of a median carina or tubercle; eight serrations on anterior margin of pronotum and asperities coarse, slender; Panama; $1.9 \mathrm{~mm} .$. 5. laevigatus (Blandford)

- Frons with fine, often obscure, subaciculate rugosities; a fine median carina extending from epistoma to above upper level of eyes (lower half sometimes obsolete); lower frons often flattened or slightly, transversely impressed; Oaxaca to Colombia; $1.5-1.8 \mathrm{~mm}$

2. lepidus Wood

4(1). An arcuate row of at least five rather coarse, longitudinally elongate tubercles at upper level of eyes, median one continued dorsad as short median carina; Texas and Florida to Brazil; 2.0-2.4 mm
3. seriatus Eggers

- Frons bearing only one rather well-developed (median) tubercle at upper level of eyes, rather coarsely rugose-punctate; Florida and Colima to Brazil, etc.; $1.4-1.8 \mathrm{~mm}$ 4. heveae (Hagedorn)

## 1. Cryptocarenus diadematus Eggers

Cryptocarenus diadematus Eggers. 1937, Rev. de Ent. 7:80 (Holotype, female; Corumba, Matto Crosso, Brazil; U.S. Nat. Mus., 60247)
Diagnosis.- This species is distinguished by the broadly convex frons, which is rather coarsely, broadly subgranulate-punctate from the epistoma to the upper level of the eyes, and by the larger average size.

Female. - Length 2.3-3.0 mm, 2.7 times as long as wide; color light reddish brown.

Frons broadly convex, a short, low, median carina at upper level of eyes; surface sub-granulate-punctate from epistoma to upper level of eyes, sculpture changing abruptly at upper level of eyes to finely rugose; vestiture of fine, moderately abundant, short, inconspicuous hair.

Pronotum 1.1 times as long as wide; sides almost straight and parallel on basal half; rather abruptly arcuately converging then constricted just before rather broadly
rounded anterior margin; anterior margin armed by 14-16 rather coarse teeth; posterior areas smooth, shining, with a few minute points, punctures very fine, moderately close. Vestiture of sparse short hair.

Elytra 1.7 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, punctures very small, shallow; interstriae at least three times as wide as striae, smooth, shining, punctures obsolete, minute points often indicated. Declivity moderately steep, convex; sutural striae narrowly impressed, interstriae 2 feebly impressed; interstriae with fine, rather widely spaced punctures. Vestiture confined to declivity, consisting of sparse, erect, interstrial bristles of moderate length, each slightly flattened on its distal half.

Male.-Similar to female except 1.4 mm , stouter; eye reduced in size; punctation of frons simple; surface of pronotum and elytra
callow, details of features not clearly defined. Only one callow example at hand.

Distribution.- Oaxaca to Brazil.
MEXICO: Oaxaca: Matías Romero, 29-VI-67, 150 m , No. 121, Scriania, S. L. Wood. COSTA RICA: "Costa Rica." XII-65., Avocado, No. 582 . N. L. II. Krauss. PANAM1A: Ft. Clayton, Canal Zone, 22-XII-63, 30 m , No. 332 tree branch, S. L. Wood; Summit, Saraea indica. OTHER COUNTRIES: Jamaica, Colombia, Venezuela, Brazil.

Hosts.- Persea americana, Saraca indica, Serjania sp., and many other lianas, shrubs, and trees (in Venezuela).

Biology. - As described for the genus.
Notes. - The above treatment was based on the holotype and on 61 other specimens.

## 2. Cryptocarenus lepidus Wood

Cryptocarenus lepidus Wood, 197I, Brigham Young Univ. Sci. Bull., Biol. Ser. I5(3):36 (Holotype, female: Beverley, Limón, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from diadematus Eggers by the smaller size, by the darker color, by the more finely sculptured frons, and by the median, subcarinate elevation on the lower frons.

Female.- Length $1.5-1.8 \mathrm{~mm}, 2.6$ times as long as wide; color dark reddish brown.

Frons very weakly, transversely impressed on lower half, a weak median carina usually extending from epistomal margin to upper level of eyes; surface rather coarsely sub-granulate-punctate to well above upper level of eyes, transition in sculpture above eves gradual; vestiture about as in diadematus.

Pronotum 1.0 times as long as wide; as in diadematus except anterior margin armed by about 10 teeth.

Elytra about as in diadematus except strial punctures deeper, slightly larger, minute impressed points more evident; declivital interstriae 2 not at all impressed; interstrial scales shorter.

Male.- Presumably differing as in diadematus; only one male, its head and prothorax missing, was available for study.

Distribution.- Oaxaca to Colombia.
MESICO: Oaxaca: 11 km N Matias Romero, 24-VI67, 150 m , No. I2I, Serjania, S. L. Wood. Veracruz: 8 km S San Andres Tuxtla, 5-V-69, D. E. Bright. GUATEMALA: Palín, Esquintla, I9-V-64, 350 m , No. 59I, Cola de Pavo, S. L. Wood. COSTA RICA: Playon, San José, 22-II-64, 50 m , No. 449, Canavalia, S. L. Wood; Santa Ana, San José, 30-VIII-63, 1300 m , No. I58, liana, S. L. Wood; Beverley, Limón, 26-VIII-63, 7 m , No. I54, liana,
S. L. Wood; Volcán, Puntarenas, II-XII-63, 700 m , No. 304, tree branch, S. L. Wood. PANAMA: Cerro Campana, 26-V1I-66, 1000 m , No. 32, tree branch, S. L. Wood; Río IIato, 22-V-60, V. J. Tipton. COLOMBIA: 24 km E Barbosa, Antioquia, IS-VII-70, 1200 m, No. 694. Nciopia, S. L. Wood; Caicedonia, Valle de Cauca, 30-VI-59, Coffea robusta. J. Restrepo.

Hosts.- Canavalia villosa, Coffea robusta, Seriania sp., Xeiopia sp.

Biology.- As described for the genus.
Notes.- The above treatment was based on the type series of 27 specimens and on 22 other specimens.

## 3. Cryptocarenus seriatus Eggers

Fig. I94

Cryptocarcuus scriatus Eggers, 1933, Orig. Mem. Trav. Lah). Ent. Paris $I(I): 10$ (Holotype, female; Nouveau Chantier, French Guayana; Paris Mus.)
Criptocarenus adustus Eggers, 1933, Orig. Mem. Trav. Lab. Ent. Paris 1(1):I1 (Holotype, female; St. Jean du Maroni, French Guayana; Paris Mus.); Wood. 1972. Great Basin Nat. 32:194. Synonymy Tachyderes floridensis Blackman, 1943. J. Washington Acad. Sci. 33:36 (Holotype, female; Paradise Key, Florida; U.S. Nat. Mus., 56415); Schedl, 1962, Ent. Blatt. 58:205. Synonymy
Cryptocarcmus bolicianus Eggers, 1943, Mitt. Münchner Ent. Ges. 33:356 (Holotype, female: Cochabamba, Bolivia; U.S. Nat. Mus.): Wood, 1975, Great Basin Nat. 35:21. Synonymy
Diagnosis.- This species is distinguished by the size, by the shallowly concave frons, and by the transverse row of about five frontal tubercles at the upper level of the eyes.

Female.- Length 2.0-2.4 mm, 2.6 times as long as wide; color rather light reddish brown.

Frons shallowly concave on median threefifths from epistoma to upper level of eyes, its upper margin armed by a transverse row of five widely spaced tubercles, median one distinctly larger; surface of concavity rather finely, deeply, closely punctured, upper and lateral areas punctate-granulate, granulations usually arranged in indefinite longitudinal rows; vestiture inconspicuous.

Pronotum 1.06 times as long as wide; as in diadematus Eggers except sides weakly arcuate; anterior margin armed by eight teeth.

Elytra as in diatematus, except interstrial bristles very slightly shorter.

Male.-Similar to female except 1.5-1.6 $\mathrm{mm}, 2.5$ times as long as wide; eye reduced in size; one or more pronotal teeth absent;
surface sculpture on pronotum and elytra obscure, not sharply formed.

Distribution.-S Texas and Florida to Brazil and Bolivia.

USA: Florida: Big Pine Key, Biscayne, Everglades N.P., Grassy Key, Key Largo, Key Vaca, Key West, Lower Matecumbe Key, Ochoppee, Paradise Key, Royal Palm Hammock St. Pk., Sebring, Sugar Loaf Key. Texas: Brownsville. MEXICO: Colima: 3 km W Armeria. Nayarit: San Blas. Oaxaca: 29 km N Matías Romero. Sinaloa: Mazatlan. HONDURAS: Olanchito. Zamorano. COSTA RICA: Playon, Santa Ana. OTHER AREAS: Cuba, Haiti, Virgin Islands, Jamaica, Venezuela, Bolivia, Brazil.

Hosts.- Canavalia villosa, Chenopodium ambrosioides, Conocarpus erecta, Dipholis salicifolia, Ficus aurea, Ipomoea pes-caprae, Mangifera indica, Metopium toxiferum, Persea borbonea, Pithecellobium guadaloupense, Rhacoma crossopetalum.

Biology.- As described for the genus.
Notes. - The above treatment was based on the holotypes of seriatus, adustus, bolivianus, and floridenus, and on 79 other specimens.

## 4. Cryptocarenus heveae (Hagedorn)

 Figs. 192-194Stephanoderes heveac Hagedorn, 1912, Rev. Zool. Afr. 1:338 (Lectotype, female; Eala, Congo; Tervuren Mus., present designation)
Cryptocarcuus caraibicus Eggers, 1937, Rev. de Ent. 7:82 (Holotype, female; Guadeloupe; U.S. Nat. Mus., 60246); Wood, I975, Great Basin Nat. 35:393. Synonymy
Tachyderes parcus Blackman, 1943, J. Washington Acad. Sci. 33:36 (Holotype, female; Cayamas, Cuba; U.S. Nat. Mus., 56416); Wood, 1962, Great Basin Nat. 22:78. Synonymy
Cryptocarenus porosus Wood, 1954, Univ. Kansas Sci. Bull. 36(2):I014 (Holotype, female; Royal Palm Hammock St. Pk., Florida; Snow Ent. Mus., Univ. Kansas); Wood, 1957. Canadian Ent. 89:396. Synonymy
Diagnosis.- This species is distinguished from lepidus Wood by the rather strongly, transversely impressed frons, with longitudinal rugae above upper level of eyes arranged to form a transverse row of one to five (usually three) indefinite denticles.

Female.- Length $1.4-1.8 \mathrm{~mm}, 2.6$ times as long as wide; color very dark brown.

Frons rather strongly, transversely impressed from epistoma to upper level of eyes; surface of impressed area rather closely, deeply punctured, punctures on lower third not at all rugose; surface above and near upper level of eyes rugose-punctate, indefinite
rugae arranged in longitudinal rows and ending in three (rarely five) indefinite denticles, median one much larger and never continued ventrad as a carina into impressed area.

Pronotum as in lepidus; anterior margin usually armed by eight teeth. Elytra as in lepidus.

Male.-Similar to female except length $1.0 \mathrm{~mm}, 2.5$ times as long as wide; eye reduced in size; some pronotal teeth absent; surface sculpture less clearly formed.

Distribution.- Florida and Colima to Brazil; Africa.

USA: Florida: Everglades Nat. Pk., 6-VIl-51, Vitis, S. L. Wood; Royal Palm Hammock St. Pk., 22-VI-51, Vitis, S. L. Wood. MEXICO: Colima: 3 km E Armeria, 28-VI$65,70 \mathrm{~m}$, No. 130, liana, S. L. Wood. Veracruz: 37 km N Matías Romero, 29-VI-67, 100 m , No. 125, tree branch, S. L. Wood. Costa RICA: Playón, 22-II-64, 50 m , No. 449, Canavalia villosa, S. L. Wood. PANAMA: Madden Forest, Canal Zone, 2-I-64, tree branch, S. L. Wood. OTHER COUNTRIES: Cuba, Jamaica, Colombia, Venezuela, Brazil, Ghana, Congo.

Hosts.- Canavalia villosa, Vitis, and other lianas, shrubs, and trees in other tropical countries.

Bıology.- As described for the genus.
Notes.- The above treatment was based on three syntypes of heveae, on the holotypes of caraibicus, parous, and porosus, and on 127 other specimens. Three female syntypes of heveae are at the Tervuren Museum; all are labeled: Musée Du Congo Belge; Eala, Bakusu (lith 1160 m, 1911); D. Hevea brasiliensis. The first specimen also bears a printed label "Holotypus" and also a pencil label "Hypothenemus, Congo, 1911." The second and third specimens also bear a printed label "Paratypus." Because Hagedorn did not designate a holotype and because a lectotype has not been designated in print by subsequent workers, I here designate the first specimen as the lectotype of Stephanoderes heveae Hagedorn.

## 5. Cryptocarenus laevigatus (Blandford)

Hypothenemus laevigatus Blandford, 1904, Biol. Centr. Amer., Coleopt. 4(6):230 (Lectotype, female; Los Remedios, Chiriquí, Panama; British Mus. Nat. Hist., present designation)
Diagnosis.- This species is distinguished from lepidus Wood by the more convex, punctured frons that is entirely devoid of rugae, tubercles, or a carina, by the large, slender, pronotal asperities and anterior
serrations, and by the slightly longer, more slender elytral setae.

Female.- Length $1.9 \mathrm{~mm}, 2.4$ times as long as wide; color rather dark yellowish brown.

Frons very broadly convex; surface shining, coarsely, closely punctured from epistoma to slightly above upper level of eyes; no indication of rugae, tubercles, or carina; vestiture of sparse, fine, long hair.

Pronotum as in lepidus except asperities and anterior serrations higher.

Elytra 1.5 times as long as wide; as in lepidus except strial punctures very slightly larger, impressed points obscure or absent: declivital interstriae 2 as wide as 1 or 3 ,
bristles distinctly longer than width of discal interstriae, each slightly flattened on its apical fourth.

Distribution. - Panama.
PaNama: Los Remedios, Chiriquí, G. C. Champion.
Notes.- Blandford's syntypic series of laevigatus is composite. Only three of the original four female specimens are now in the British Museum; one of the Bugaba specimens is missing. The first specimen, from Los Remedios, has been regarded as the type for many years: it is here designated as the lectotype of Hypothenemus laevigatus Blandford. The second specimen, from Chontales, Nicaragua, is of heveae (Hagedorn). The above treatment was based on the lectotype.

# Tribe CORTHYLINi 

Corthyli LeConte, 1876, Proc. Amer. Philos. Soc. 15:347 (Type-genus: Corthylus Erichson, 1836)
Pityophthoridae Eichhoff, 1878, preprint of Mém. Soc. Roy. Sci. Liége (2)8:173 (Type-genus: Pityophthorus Eichhoff, 1864)
Araptidae Eichhoff, 1878, preprint of Mém. Soc. Roy. Sci. Liége (2)8:305 (Type-genus: Araptus Eichhoff, 1872)
Amphicranidae Eichhoff, 1878, preprint of Mém. Soc. Roy. Sci. Liége (2)8:460 (Type-genus: Amphicranus Erichson, 18.36)

Anatomical features.- The frons is usually sexually dimorphic, but the dimorphism is expressed in numerous different ways, the eye is emarginate, the antennal funicle is $1-5$-segmented, the club if flattened, when sutures are present those on the posterior face are almost equal to those on the anterior face, the pronotum is usually declivous and asperate in front, the lateral margins may be rounded or marked by a fine, raised line, the procoxae are contiguous, the metepisternum has a unique locking mechanism (a groove) for the elytra and is largely covered by the elytra, the costal margin of the elytra usually descends slightly toward the apex, and the tibiae are slender and rarely armed by more than three denticles.

Biological features.- Both monogamy and heterosanguineous polygyny are widespread. The subtribe Pityophthorina includes phloeophagous and spermophagous forms, Corthylina xylomycetophagous forms. Eggs are placed in niches or in fully formed cradles (Corthylus). Larval mines in Pityophthorina are independent, follow a definite course, and rarely cross; in Corthylina they enlarge the egg niches into cradles just large enough to accommodate the adult stage. Symbiotic fungi furnish the principal food of the Corthylina. Two species of Araptus practice consanguineous polygyny and have dwarfed, apparently haploid males.

Taxonomy.- Except for Pityophthorus, which has a few representatives in Eurasia and Africa, this tribe is uniquely American. The differences between genera are minute and classification is unusually difficult.

Genus Styphlosoma Blandford
Styphlosoma Blandford, 1904, Biol. Centr. Amer., Coleopt. $4(6): 232$ (Type-species: Styphlosoma granulutum Blandford, monobasic)
Diagnosis.- This genus is distinguished from Dendroterus Blandford by the 5 -segmented antennal funicle, by the strongly procurved sutures of the antennal club, and, in the female, by the deeply emarginate epistoma and the mandibular spine.

Description.- Length $1.3-1.6 \mathrm{~mm}, 2.4$ times as long as wide; color very dark brown.

Frons dimorphic, male transversely carinate at upper level of eyes, impressed below; female frons flattened with epistoma very deeply emarginate, a pair of mandibular spines projecting into emargination. Antennal scape elongate; funicle 5 -segmented; club flattened, with sutures strongly procurved, suture 1 extending one-fourth and 2 threefourths of club length from base. Pronotum declivous and finely asperate on anterior half; summit poorly defined; transition from asperate to punctured areas gradual. Elytra striate; declivity steep, unarmed.

Distribution.- Costa Rica to Venezuela; two species are known.

Biology.- The thick bark on the bole of fallen trees is selected for attack. The nuptial chamber is a small tabular cavity having its longest axis perpendicular to the surface of the wood and its width parallel to the grain of the wood. From the inner extremity of the nuptial chamber one or two egg galleries branch from the upper and one or two from the lower corner near the cambium. The egg galleries gradually descend through the
phloem then continue for about two thirds of their length along the cambium layer. The eggs evidently are deposited in niches along the sides of the gallery only after it reaches the cambium. The larval mines follow an erratic course in the cambium region (only very young larvae were observed).

## Styphlosoma granulatum Blandford

Fig. 195
Styphlosoma granulatum Blandford. 1904. Biol. Centr. Amer., Coleopt. 4(6): 232 (Holotype, male; Bugaba, Chiriquí, Panama; British Mus. Nat. Hist.)
Diagnosis.- This species is distinguished from subulatum Wood by the flat, less strongly impressed female frons, with punctures slightly larger, by the less deep, somewhat obtuse female epistomal emargination, and by the slightly wider declivital impression on the elytra.

Female.- Length $1.3-1.5 \mathrm{~mm}, 2.4$ times as long as wide; color very dark brown.

Frons flat from eve to eve from epistomal margin to vertex; epistomal margin very deeply emarginate, emargination almost attaining upper level of eves, rather broadly Ushaped, wider than deep, its arms diverging slightly; surface almost smooth, with dense, uniformly distributed, rather coarse, deep punctures over entire flattened area; dorsomesal angle of cutzing surface of mandibles greatly extended and curved cephalad into a median, projecting process; this mandibular process projecting from fundus of epistomal emargination a distance equal to almost half length of scape; vestiture rather abundant, very short, inconspicuous.

Pronotum 1.06 times as long as wide; widest near base, sides feebly arcuate and converging very slightly on basal half, rather broadly rounded in front; anterior margin weakly serrate; summit at middle, broad; anterior slope finely asperate, dense subasperate granules continuing to base in discal area; posterolateral areas closely, deeply, rather coarsely punctured. Vestiture of very short, coarse, close setae.

Elytra 1.4 times as long as wide: sides almost straight and parallel on basal two-thirds, very broadly rounded behind; striae 1 weakly impressed, strial punctures moderately coarse, rather deep, close; interstriae as wide as striae, smooth, punctures fine, close, in
rows except moderately confused toward base. Declivity very steep, appearing somewhat flattened from dorsal aspect; strial punctures smaller than on disc; interstrial punctures about as on disc; interstriae 2 narrowed, strongly, narrowly impressed on central two-thirds of declivity. Vestiture on striae and alternate interstrial setae of short, suberect, rather coarse hair; irregular somewhat alternate interstrial setae forming rows of slightly longer scales, each scale about three times as long as wide (alternate arrangement of scales and stout hair much less regular than in subulatum).

Male.-Similar to female except epistoma not emarginate; frons with a strongly developed, transverse carina at upper level of eves, convex above, strongly, transversely impressed below carina, surface coarsely, closely punctured, upper area also reticulate.

Distribution.- Costa Rica to Panama.
Costa RiCa: Finca Taboga, 15 km SE Cañas, Guanacaste, 2-11-67, Spondias momhin. R. W. Mathews. PANAMA: Bugala. Chirigui, G. C. Champion.

Host.-Spondias mombin.
Biology.- As described for genus.
Notes.- The above treatment was based on a male compared to the type by R. T. Thompson and on 108 other specimens.

## Genus DENDROTERUS Blandford

Dendroterus Blandford, 1904, Biol. Centr. Amer., Coleopt. 4(6):233 (Type-species: Dendroterus mexicamus Blandford, subsequent designation by Hopkins, I914. Proc. U.S. Nat. Mus. 48:120)
Plesiophthorus SchedI. 1940, An. Esc. Nac. Cienc. Biol.,
Mexico 1:34.3 Type-species: Plesiophthorus per-
spectus Schedl, monobasic): Wood, 1959, Great Basin Nat. 19:2. Synonymy
Xylochilus Schedl, 1956, Pan Pacif. Ent. 32:31 Typespecies: Xylochilus insularis Schedl $=$ Dendroterus sallaci Blandford, original designation); Wood. 1972, Creat Basin Nat. 32:191. Synon!my

Fig. 195. Styphlosona granulatum, heads: 1, female; 2 , male.

Diagnosis.- This genus is distinguished from Styphlosoma Blandford by the 3- or 4segmented antennal funicle, by the straight to slightly recurved sutures of the antennal club, and by the entire frons and normal mandibles in the female.

Description. - Length $1.4-2.9 \mathrm{~mm}$, 2.4-2.8 times as long as wide; color yellowish brown to almost black.

Frons evenly convex in both sexes to strongly dimorphic. Antennal scape elongate; funicle 3 - or 4 -segmented (variable within a series in a few species); sutures of club straight to weakly recurved. Pronotum and elytral disc as in Styphlosoma; elytral declivity convex to weakly impressed, very steep, unarmed.

Distribution.-S California and Texas to Panama; 13 species are known.

Biology.- Unthrifty, injured, or recently cut host material of the genera Bursera and Jatropha is selected for attack. All species are polygamous and breed in phloem tissues, at times without coming in contact with the cambium region. Larvae cut individual mines that wander in the general direction away from the star-shaped parental galleries.

Notes.- The segmentation of the antennal funicle varies in this genus. In striatus and lutcolus it is usually 3 -segmented, less commonly 2 -segmented; in mexicanus, cognatus, and decipiens it is usually 4 -segmented, less commonly 3 -segmented; in the only known specimen of perspectus it is 3 -segmented. In all other material at hand the funicle is 4 -segmented. The type of perspectus was not available when the key was written.

## Key to the Species of Dendroterus

1. Pro- and mesotibiae each armed by two apical and four lateral socketed teeth; interstrial setae fine, long, one and one-half to two times as long as distance between rows; pronotal asperities coarse, less abundant, confined to anterior half, posterior half almost smooth to weakly subreticulate, shining, punctures coarse, deep, interspaces averaging as wide as punctures, not granulate; strial punctures coarse, deep, declivity moderately steep, narrowly convex; frons similar in both sexes; Texas; Jatropha spathulata; 2.1-2.9 mm

- Pro- and mesotibiae each armed by two apical and one lateral socketed teeth; interstrial setae not longer than distance between rows; pronotal asperities smaller; more abundant, often extending to part of posterior half; posterior half either strongly reticulate or much more closely punctured; frons strongly dimorphic (except sodalis); Bursera
2(1). Pronotum reticulate and finely punctured on posterior half, interspaces averaging at least twice as wide as punctures, devoid of granules; strial punctures very small, less than half as wide as interstriae; interstrial punctures obsolete (confused impressed points usually present); elytral declivity more gradual, more narrowly convex
Posterior areas of pronotum shining, much more closely, coarsely, deeply punctured, often granulate; strial punctures larger; interstrial punctures distinctly impressed, rather coarse in most species; elytral declivity steeper, more broadly convex to moderately impressed
3(2). Female frons convex above, flattened on less than lower half, pubescence short, sparse; elytral surface brightly shining, strial punctures more sharply impressed, interstriae with comparatively few, obscure, impressed points; sutural interstriae on declivity distinctly elevated; Guatemala; Bursera; 1.4-1.8 mm .....
- $\quad$ Female frons flattened to upper level of eyes and ornamented by rather abundant, moderately long hair; strial punctures not sharply impressed, interstriae either subreticulate or with numerous, deep, impressed points; sutural interstriae not elevated

4(3). Elytral disc shining, with dense, deep, confused, minute, impressed points; interstrial setae on declivity more widely spaced, separated by distances almost equal to length of a seta; upper half of female frons subconcave, median area at upper level of eyes distinctly elevated; Costa Rica; Bursera simarubra; $1.9-2.0 \mathrm{~mm}$ between setae of same row; upper area of female frons flat, without median prominence; Guatemala; Bursera; $1.7-2.1 \mathrm{~mm}$
4. eximius Wood

5(2). Discal interstriae with numerous, strongly confused punctures; female frons subconcavely impressed and ornamented by rather abundant long hair from epistoma to well above eyes; male frons with a conspicuous transverse impression just below upper level of eyes; punctures of declivital interstriae not granulate; Costa Rica and Panama; Bursera simarubra; 2.3-2.9 mm sex

6(5). Male frons weakly to moderately convex above epistoma, without special sculpture; female frons flattened to weakly convex and ornamented by a conspicuous brush of long hair; either larger than 2.0 mm or else declivital interstriae armed by granules

- Female frons with a conspicuous, sharply elevated, transverse carina at upper level of eyes; male frons convex, usually slightly inflated above epistomal margin; 1.3-2.0 mm
7(6). Declivital punctures on interstriae not granulate; lateral areas of male epistoma conspicuously elevated; female frons punctate-granulate, weakly convex, vestiture of uniform length and distribution; $1.9-2.7 \mathrm{~mm}$
- Declivital interstriae each armed by a row of granules; male epistoma without elevations; female frons at least partly flattened, vestiture more abundant and longer at margins; $1.5-2.1 \mathrm{~mm}$
8(7). Body slender, 2.8 times as long as wide; male frons more broadly, evenly rounded, epistomal elevations rather poorly developed; punctures on pronotal disc coarse; lower elytral declivity more distinctly impressed; Nayarit; Bursera; $1.9-2.2 \mathrm{~mm}$
- Body rather stout, 2.5 times as long as wide; male frons strongly convex above, much more weakly convex below, epistomal elevations moderately to very strongly elevated; punctures on pronotal disc averaging smaller; lower elytral declivity less distinctly impressed; Nayarit to Oaxaca; Bursera; $1.8-2.7 \mathrm{~mm}$...... 7. mexicanus Blandford

9(7). Discal interstriae as wide as striae, strial punctures coarse; granules on pronotal disc larger, punctures largely obliterated by reticulation; strial punctures on declivity larger, interstrial granules averaging smaller; frons finely granu-late-punctate in both sexes; female frons often with a callus at upper margin of pubescent area; Nayarit to Costa Rica; Bursera; 1.6-1.9 mm (8. perspectus Schedl fits near here)

- Discal interstriae at least one and one half times as wide as striae, strial punctures smaller; pronotal disc with punctures distinct, granules very small, no evidence of reticulation; frons punctate
10(9). Female frons weakly convex on upper two-thirds, very finely punctured; epistomal process slightly elevated medially, its lower margin usually marked by a procurved line separate from epistomal margin; discal interstriae smooth, impressed points almost obsolete, sparse; male declivity with interstriae 2 more strongly impressed, tubercles on 1 and 3 larger; Costa Rica; Bursera simarubra; $1.5-1.9 \mathrm{~mm}$

10. resolutus Wood

- Female frons flat to feebly impressed on upper two-thirds, rather coarsely punctured; epistomal process not indicated, epistoma not elevated in median area; elytral dise smooth, impressed points usually clearly indicated, more numerous; male declivital interstriae 2 less strongly impressed, punctures on 1 and 3 smaller; Jalisco to Oaxaca; Bursera; 1.6-2.0 mm .

11. decipiens Wood

11(6). Interstrial setae slender, almost hairlike; female transverse carina occupying median half of distance between eyes; male frons with weak transverse impression at upper level of eyes, subinflated below, impression marks abrupt transition in surface sculpture of upper and lower areas; S California to Baja California; Bursera microphylla; $1.6-2.0 \mathrm{~mm}$
13. striatus (LeConte)

- Interstrial setae stout, almost scalelike on declivity; female transverse carina occupying median three-fourths of distance between eyes; male frons evenly convex from epistoma to vertex; change in sculpture gradual; Nayarit to Chiapas; Bursera; 1.3-1.7 mm

12. luteolus (Schedl)

## 1. Dendroterus texanus Wood Fig. 196

Dendroterus texanus Wood, 1959, Great Basin Nat. 19:4
(Holotype, male; Presidio, Texas; U.S. Nat. Mus.)
Diagnosis.- This unique species is distinguished by the absence of secondary sexual characters on the frons, and by the smooth surface of the pronotal disc between the coarse punctures.

Female.- Length 2.1-2.9 mm, 2.8 times as long as wide; body color dark brown.

Frons rather weakly convex from eye to eye, epistomal margin gradually elevated; surface almost smooth, with rather coarse, abundant, subgranulate punctures; vestiture sparse, short, hairlike. Eye deeply emarginate; finely granulate. Antennal funicle 3segmented, pedicel almost equal in length to combined lengths of segments 2 and 3; club oval, sutures straight except recurved at extreme side margins.

Pronotum 1.1 times as long as wide; widest at base, sides feebly arcuate, converging very slightly toward rather narrowly rounded anterior margin; anterior margin armed by eight rather large, subcontiguous teeth,
median ones slightly longer; summit near middle, indefinite; surface of disc very minutely reticulate, between coarse, deep, abundant punctures, posterior areas devoid of granules; lateral and basal lines not present. Vestiture fine, semierect, hairlike, of moderate length.

Elytra 1.7 times as long as wide; sides straight and subparallel on basal two-thirds, gradually, rather narrowly rounded behind; striae not impressed, punctures rather coarse, deep; interstriae as wide as striae, almost smooth, punctures fine, about equal in number to those of striae. Declivity moderately steep, convex; striae 1 and 2 slightly impressed, punctures greatly reduced in size, but deeply, distinctly impressed; interstriae 1 slightly elevated, punctures as on dise but some very feebly granulate. Vestiture consisting of minute, inconspicuous strial hairs, and moderately long, erect interstrial hairlike setae; not longer on declivity.

Male.-Similar to the female; distinguished externally only by segmentation of abdomen.

Distribution.- Texas.

USA: Texas: Juniper Canyon, Big Bend N.P., 5-VI-70, Jatropha spathulata, L. B. and C. W. O'Brien; Presidio, I6-V-47, J. spathulata, J. H. Russell; Starr Co., 27-III-60; Uvalde Co., 13-v1-49.

Host.- Jatropha spathulata.
Biology.-Specimens were reared from branches of the above shrub.

Notes.- The above treatment was based on the type series of 118 specimens, and on 21 other specimens.

## 2. Dendroterus sodalis Wood

Dendroterus sodalis Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):44 Holotype, female; Volcán de Agua, Esquintla. Guatemala: Wood Coll.)
$\mathrm{D}_{\text {lagnosis.- This species is distinguished }}$ from eximius Wood by the convex subglabrous female frons, by the subshining pronotum and elytra, with sharply impressed, moderately large punctures, and by the weakly impressed declivital interstriae 2.

Female.- Length $1.4-1.8 \mathrm{~mm}, 2.6$ times as long as wide; color dark reddish brown.

Frons broadly convex; surface subshining, small, finely granulate punctures rather close, uniformly distributed; vestiture very short, hairlike, moderately abundant. Funicle 4segmented.

Pronotum 1.2 times as long as wide; as in eximius except teeth on anterior margin much smaller; posterior area subshining, surface subreticulate with many impressed points, punctures moderately large, deep, sparse. Glabrous.

Elytra 1.6 times as long as wide, 1.4 times as long as pronotum; sides straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, punctures moderately large, deep; interstriae almost twice as wide as striae, almost smooth, shining, impunctate except on 1 and on others toward declivity. Declivity steep, broadly convex; strial punctures slightly smaller, not as deep; interstriae 1 abruptly, slightly elevated, 2 impressed, 3 weakly elevated, each with a row of fine rounded granules except absent on lower half of 2 .

Fig. 196. Dendroterus spp., heads: a, mexicanus, male; b, texanus, female; c, resolutus, female, d, same, female; e, eximius, male, f, same, female; g, luteolus, male, h, same, female.

Vestiture of moderately long, coarse, rather widely spaced hair on and near declivity.

Male. - Similar to female except frons more narrowly convex, vestiture less distinct.

Distribution.- Guatemala.
GUATEMALA: Volcán de Agua, Esquintla, 19-V-64. 1000 m , No. 595, Bursera, probably simarubra, S. L. Wood.

Biology. - Specimens were taken from the outer bark of a limb.

Notes.- The above description was based on the type series of 45 specimens.

## 3. Dendroterus parilis Wood

Dendroterus parilis Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):44 (Holotype, female; Santa Ana, San José, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from the closely allied eximius Wood by the more strongly impressed female frons, by the deeper pronotal punctures, by the greatly reduced strial punctures, by the much more numerous, deeper, impressed points on the elytra, and by the much less abundant elytral hair.

Female.- Length $1.9-2.0 \mathrm{~mm}, 2.8$ times as long as wide; color very dark reddish brown.

Frons as in eximius except very slightly more strongly impressed. Pronotum as in eximius except discal reticulation stronger, punctures deeper, more sharply impressed.

Elytra as in eximius except surface shining, strial punctures minute, shallow, some of them little larger than abundant, sharply impressed, minute points; surface of disc with many shallowly impressed, irregular lines; interstrial punctures on declivity less distinctly granulate. Vestiture about half as abundant as in eximius.

Distribution.- Costa Rica.
COSTA RICA: Santa Ana, San José, 8-X1-63, 1300 m , No. 253, Bursera simarubra, S. L. Wood.

Biology.- Specimens were taken from the outer bark of a small shaded-out branch of a living fence row tree.

Notes. - The above treatment was based on the two females in the type series.

## 4. Dendroterus eximius Wood

Fig. 196
Dendroterus eximius Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):44 (Holotype, female; Lago Amatitlan, Esquintla, Guatemala; Wood Coll.)

Diagnosis.- This species is distinguished by characters presented in the above key.

Female.- Length $1.7-2.3 \mathrm{~mm}, 2.8$ times as long as wide; color reddish brown.

Frons broadly, transversely impressed on lower half, epistoma slightly elevated; surface reticulate above, becoming smooth below, upper area with small, moderately abundant, shallow punctures; vestiture moderately abundant, of rather long, fine hair. Antennal funicle with four strongly compressed segments; club longer than wide.

Pronotum 1.2 times as long as wide; widest on basal half, sides weakly arcuate, narrowly rounded in front; anterior margin armed by about six teeth, median pair much larger; summit at middle; asperities rather coarse, not continued behind summit; posterior area reticulate, punctures very small, shallow, rather sparse. Vestiture rather sparse, hairlike.

Elytra 1.7 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal two-thirds, narrowly rounded behind; striae not impressed, punctures rather small, shallow; interstriae wider than striae, rather obscurely reticulate, dull, punctures fine, very sparse except toward declivity. Declivity rather steep, convex; strial punctures minute, weakly impressed; interstrial punctures replaced by fine, uniseriate rows of granules. Vestiture largely confined to declivity, consisting of minute strial hair and rows of much longer, erect, interstrial hair; each hair stout, about as long as distance between rows, spaced more closely within a row; all declivital setae diverge very slightly away from suture.

Male. - Similar to female except frons convex, weakly impressed immediately above epistoma, surface very finely, obscurely punctured, vestiture sparse, inconspicuous.

## Distribution.-Guatemala.

GUATEMALA: Lago Amatitlan, Esquintla, 10-VI-64, 700 m . No. 707, Bursera, S. L. Wood; Palín, Esquintla, 19-V-64, 300 m , No. 590, Bursera, S. L. Wood.

## Host.- Bursera, probably simarubra.

Biology.- Specimens were taken from the bark of dying branches $2-6 \mathrm{~cm}$ in diameter, in living trees.

Notes.- The above treatment was based on the type series of 69 specimens and on 4 other specimens.

## 5. Dendroterus defectus Wood

Dendroterus defectus Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):45 (Holotype, female; Rincón de Osa, Puntarenas, Costa Rica; Wood Coll.)
Diagnosis.- This large species is not closely allied to any other species in the genus. It is distinguished by characters summarized in the above key.

Female.- Length 2.3-2.9 mm, 2.4 times as long as wide; color yellowish brown.

Frons broadly impressed from epistomal margin to well above eyes, flat on transverse axis, shallowly concave on longitudinal axis; surface very densely, rather coarsely punctured and evidently very finely granulate except smooth, impunctate and shining on median area along epistoma; vestiture of rather abundant, fine, moderately long hair of uniform length. Antennal funicle 4 -segmented; club wider than long.

Pronotum 1.1 times as long as wide; widest at base, sides weakly arcuate, converging slightly on basal half, feebly constricted in front of middle, rather narrowly rounded in front, with a feeble, pseudoemargination on median line; anterior margin weakly elevated, not serrate; summit indefinite, behind middle; asperities small, decreasing in size gradually from median area, posterior area punctate-subasperate to base, punctures rather small, moderately deep, some reticulation present. Glabrous.

Elytra 1.3 times as long as wide, 1.3 times as long as pronotum; sides almost straight and parallel on basal two-thirds, broadly rounded behind; striae not impressed, punctures small, moderately deep, interstriae shining, twice as wide as striae, surface with many rather deep, irregular, subtransverse lines and moderately large, impressed points, punctures small, slightly irregular. Declivity rather steep, rather broadly flattened; striae slightly impressed, punctures deeper than on disc; flattened between interstriae 4. Almost glabrous, a very few minute, hairlike setae on declivity.

Male. - Similar to female except frons strongly convex above eyes, a very strong, narrow, transverse impression on median three-fourths, area between impression and epistomal margin moderately inflated,
glabrous, coarsely punctured; posterior area of pronotum distinctly less subcrenulate.

Distribution.- Costa Rica to Panama.
COSTA RICA: Rincón de Osa, Puntarenas, II-Vili$66,50 \mathrm{~m}$, No. 51 , Bursera simarubra, S. L. Wood. PANAMA: Ft. Clayton, Canal Zone, 27-VII-66, 70 m , No. 38, B. simarubra, S. L. Wood.

Host.- Bursera simarubra.
Biology.- Specimens were taken from the bark of recently felled limbs and boles 15-40 cm in diameter.

Notes.- The above treatment was based on the type series of 99 specimens.

## 6. Dendroterus cognatus Wood

Dendroterus cognatus Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):16 (Holotype, female; Laguna Santa María, Nayarit, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from the very closely related mexicanus Blandford by the more slender form, by the more broadly, evenly rounded, more coarsely punctured male frons, by the more convex female frons with shorter, less abundant vestiture, by the more coarsely punctured pronotum and elytra, and by the more distinctly impressed elytral declivity on which there are numerous minute, impressed points. Future collecting could necessitate the reduction of this form to the rank of subspecies.

Female.- Length 1.9-2.2 mm, 2.8 times as long as wide; color black.

Frons broadly, moderately concave to epistoma; surface rather coarsely, evenly granu-late-punctate; vestiture finer, shorter, about half as abundant as in mexicanus.

Pronotum 1.23 times as long as wide; about as in mexicanus except punctures slightly larger, deeper.

Elytra 1.67 times as long as wide; outline as in mexicanus but much more broadly rounded behind; strial punctures coarser and deeper than in mexicanus, interstriae narrower than striae. Declivity slightly steeper than in mexicanus, very slightly more strongly impressed, sculpture as in mexicanus except minute impressed points larger and much more numerous. Vestiture averaging longer and coarser than in mexicanus.

Male.-Similar to female except frons as in male mexicanus, but more broadly, evenly
convex, more coarsely punctured, with lateral epistomal calli only moderately to poorly developed.

Distribution.- Nayarit.
MEXICO: Nayarit: Laguna Santa María, 6-VII-65, 1000 m , No. 194, Bursera, S. L. Wood.
Brology.- Specimens were taken from the bark of a dying branch 4 cm in diameter, on a living tree.

Notes.- The above treatment was based on the type series of 10 specimens, and on 18 other specimens, all taken from the same branch at the above locality. Due to an error in labeling, the 10 specimens in the type series were erroneously reported in the original description as being from El Salto, Durango.

## 7. Dendroterus mexicanus Blandford Fig. 196

Dendroterus mexicanus Blandford, 1904, Biol. Centr. Amer., Coleopt. 4(6):23:3 (Holotype, female; Tehuantepec. Oaxaca, Mexico; British Mus. Nat. Hist.)
Conophthocramulus umbratus Schedl, 1937, Arch. Inst. Biol. Veget. Río de Janeiro 3:168 (Ilolotype, female; Mexico, Schedl Coll.); Wood. 1976, Great Basin Nat. 36:348. Synonymy
Dendroterus confinis Wood, 1959, Great Basin Nat. 19:6 (Holotype, male; 14 miles or 23 km NW Magdalena, Jalisco, Mexico; Snow Ent. Mus., Univ. Kansas): Wood, 1972, Great Basin Nat. 32:196. Synonymy
Diagnosis.- This species is distinguished from the very closely related cognatus Wood by characters summarized in the above key.

Female. - Length $1.8-2.7 \mathrm{~mm}, 2.5$ times as long as wide; color almost black.

As in cognatus except frons slightly less strongly convex, punctures on pronotal disc averaging smaller, and lower elytral declivity very slightly less distinctly impressed.

Male.-Similar to female except frons. Frons similar to male cognatus except less strongly convex on lower half, more strongly convex above; transverse elevations on lateral thirds of epistoma moderately to very strongly elevated (geographically variable).

Distribution.- Nayarit to Oaxaca.
MEXICO: Jalisco: 2 km N Atenquique, 24-VI-65, 1000 m , No. 112, Burscra, S. L. Wood; 23 km NW Magdalena, 19-VII-53, 1000 m, Bursera, S. L. Wood. Nayarit: Volcán Ceboruco, 5-V1I-65, 1100 m , No. 187, Bursera, S. L. Wood. Oaxaca: 57 km SE Cameron, 22-VI-67, No. S8, Bursera, S. L. Wood: Totolapan, 20-VI-67, 1100 m . No. 62, Burscra, S. L. Wood: Tehuantepec, G. C. Champion.

## Hosts.- Bursera spp.

Biology.- Specimens were taken from the limbs and bole of cut or fallen trees $8-30 \mathrm{~cm}$ in diameter.

Notes.- The above treatment was based on the holotype of mexicanus, on 8 paratypes of confinis, and on 119 other specimens.

The Nayarit and Jalisco specimens average distinctly larger than those from Oaxaca, and the epistomal elevations of the male average distinctly higher than in Oaxaca specimens. The variability of these characters did not becomg apparent until long series were available for study. It is doubtful that the differences warrant the recognition of subspecies.

## 8. Dendroterus perspectus (Schedl)

Plesiophthorus perspectus Schedl, 1940, An. Esc. Cienc. Biol., Mexico 1:343 (Holotype, female; Omilteme, Guerrero, Mexico; Schedl Coll.)
Dendroterus perspectus: Wood, 1959, Great Basin Nat. 19:2
Although the type of Plesiophthorus perspectus Schedl was briefly examined at Lienz, Austria, it could not be incorporated into the above key. Notes made at that time are summarized as follows.

Holotype, female, length $1.9 \mathrm{~mm}, 2.5$ times as long as wide; similar to sallaei Blandford except pronotum much more broadly rounded in front; pronotal dise with granulation similar to sallaei but granules larger, less numerous, and more widely spaced; striae much less strongly impressed and interstrial punctures smaller than in sallaei; interstrial punctures not granulate on declivity; striae 1 and 2 on declivity very narrowly impressed; frons very shallowly concave on more than median half from epistoma to upper level of eyes, its surface covered by minute, setiferous, flattened granules, each side at upper level of concavity armed by a poorly formed carina (interrupted at median line), evidently derived from two pairs of partly fused granules; vestiture shorter, finer, and less abundant than in sallaei.

This species is unique and evidently is intermediate in phyletic position between defectus Wood and sallaei.

## 9. Dendroterus sallaei Blandford

Dendroterus sallaci Blandford, 1904, Biol. Centr. Amer., Coleopt. 4(6):233 (Holotype, female; Veracruz, Veracruz. Mexico; British Mus. Nat. Hist.)

Xylochilus insularis Schedl, 1956, Pan Pacif. Ent. 32:31 (Holotype, male; Arroyo Hondo, María Madre, Tres Marías Islands, Gulf of California; California Acad. Sci.); Wood, 1972, Great Basin Nat. 32:195. Synonymy
Diagnosis.- This species is distinguished from resolutus Wood by the larger strial punctures and proportionately narrower interstriae, by the larger granules on the pronotal disc, with the punctures and spaces between granules largely obliterated by reticulation, by the larger strial punctures and smaller granules on the elytral declivity, and by the more nearly granulate-punctate frons in both sexes.

Female.- Length $1.6-1.9 \mathrm{~mm}, 2.4$ times as long as wide; yellowish brown to rather dark reddish brown.

Frons moderately convex on upper twothirds, a distinct transverse impression on lower half, epistoma ascending to margin; epistomal margin almost straight, not modified in median area; surface rather finely punctured, with very fine granules interspersed; many specimens with a variable arcuate callus at and above upper level of eyes, usually interrupted at median line; vestiture of fine, rather long, moderately abundant hair, distinctly more conspicuous on upper half.

Pronotum as in decipiens and resolutus except discal granules larger, shining, punctures obliterated by rugose-reticulate surface of intervening spaces.

Elytra as in resolutus except strial punctures larger, deeper; interstriae about as wide as striae. Declivity more broadly rounded than in resolutus, from dorsal aspect appearing flattened on more than median half; interstriae 1 weakly elevated, 2 weakly impressed, granules uniseriate, small, rounded; strial punctures rather coarse, deep, almost as wide as interstriae. Vestiture as in resolutus and decipiens.

Distribution.- Gulf of California and Tamaulipas to Costa Rica.

MEXICO: Chiapas: Tuxtla Gutierras, 2-IV-53, R. C. Bechtel. Jalisco: La Huerta, 1-VII-65, 500 m , No. 172, flight, S. L. Wood. Nayarit: 24 km E San Blas, 12-VII-65, 250 m , No. 230, Burscra simarubra, S. L. Wood. Oaxaca: 31 km SE Caneron, 21-VI-67, No. 77. Bursera. S. L. Wood: Donaji, 17-IV-53. R. C. Bechtel: Matías Romero, 24-VI-67, 200 m , No. 91, B. simarubra, S. L. Wood: Tehuantepec, 23-VII-64, at light, P. J. Spangler. Tamaulipas: Bocatoma, 7 km SE Gomez Farias, $18-\mathrm{V}-79$, E. G. Riley. Tres Marías Islands: Arroyo Hondo, María Madre,

17-V-25, H. H. Keifer. COSTA RICA: 21 km SE Liberia, Guanacaste, I0-VII-66, B. simarubra, S. L. Wood.

Hosts.- Bursera simarubra, B. sp.
Biology.- Specimens were taken from the phloem of broken limbs $15-25 \mathrm{~cm}$ in diameter.

Notes.- The above treatment was based on the holotypes of sallaei and insularis and on 82 other specimens. The specimen of insularis in the Schedl collection labeled female holotype actually is a paratype.

## 10. Dendroterus resolutus Wood <br> Fig. 196

Dendroterus resolutus Wood, 1971, Brigham Young Univ. Sci. Bull.. Biol. Ser. $15(3): 45$ (Holotype, female: Playa del Coco, Guanacaste, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from sallaei Blandford by the very different frons in both sexes, by the smooth, shining pronotal disc with the punctures much more sharply defined, and by the finer elytral punctures.

Female.- Length $1.5-1.9 \mathrm{~mm}, 2.7$ times as long as wide; color yellowish brown to almost black.

Frons moderately convex on upper twothirds, lower third broadly, rather strongly, transversely impressed, epistomal margin slightly elevated, a distinct, median tubercle on epistomal margin; surface shining, punctures moderately large, rather deep, sparse in central area, rather dense on lateral and upper margins, extending well above upper level of eyes; vestiture of fine, long hair, sparse at center, rather abundant on margins. Antennal funicle 4 -segmented; club 1.3 times as long as wide, sutures straight, 1 partly septate.

Pronotum 1.2 times as long as wide; as in sallaei except asperities distinctly larger; posterior area shining, deeply, coarsely, closely punctured. Hairlike vestiture short on disc, longer at sides, moderately abundant.

Elytra 1.5 times as long as wide, 1.3 times as long as pronotum; sides almost straight and parallel on basal two-thirds, broadly rounded behind; striae not impressed, punctures moderately small, deep; interstriae shining, about as wide as striae, punctures rather small, uniseriate. Declivity steep, flattened, striae 1 and 2 moderatey impressed, punctures as on
disc; interstriae 1 convex, weakly elevated, 2 impressed but weakly convex, 3 weakly elevated; all interstriae with a row of fine, rounded tubercles, those on 2 smaller. Vestiture of rows of stout, moderately long, interstrial hair, much shorter on declivity.

Male.-Similar to female except frons convex to epistoma, punctures rather coarse, uniformly distributed, vestiture sparse, evenly distributed, epistomal tubercle absent.

Distribution.- Costa Rica.
COSTA RICA: Playa del Coco, Guanacaste, I8-X-63, 15 m , No. 499, Bursera simarubra, S. L. Wood.

Biology.- Specimens were taken from the bark of limbs, bole, and the stumps of unthrifty or recently cut material $7-40 \mathrm{~cm}$ in diameter.

Notes.- The above treatment was based on the type series of 30 specimens.

## 11. Dendroterus decipiens Wood

Dendroterus decipiens Wood, 1959, Great Basin Nat. 19:5 (Holotype, male; Tequila, Jalisco, Mexico; Snow Ent. Mus., Univ. Kansas)
Diagnosis.- This species is distinguished from resolutus Wood by characters summarized in the above key.

Female.- Length $1.5-1.9 \mathrm{~mm}, 2.5$ times as long as wide; color very dark brown.

Frons flattened from eye to eye, more finely, closely punctured and ornamented by a brush of long, fine, incurved yellow setae, those at center of brush somewhat shorter; antennal funicle variable, (usually) 4segmented.

Pronotum 1.1 times as long as wide; widest just behind middle, sides weakly arcuate, anterior margin rather broadly rounded and armed by 10 coarse, subcontiguous teeth; summit at center, indefinite; anterior asperate region gradually blending into coarsely, closely granulate posterior area on disc, almost smooth between rather coarse, close, deep punctures in posterolateral areas; lateral and basal lines absent. Vestiture semierect, hairlike, of moderate length.

Elytra 1.4 times as long as wide; sides straight and subparallel on basal threefourths, rather abruptly, very broadly rounded behind; striae not impressed except 1 , punctures rather small, distinct but not deep; interstriae wider than striae, smooth, punctures almost as large as those of striae
and slightly less numerous and less distinctly impressed. Declivity very steep; interstriae 2 slightly impressed; all interstriae with a row of fine granules; striae not impressed, punctures reduced in size. Vestiture consisting of fine, rather short, recumbent strial hair, and longer, erect, rather coarse interstrial setae, perhaps coarser but not longer on declivity.

Male. - Similar to female except frons moderately convex except flattened near bisinuate epistomal margin, surface smooth, punctures rather coarse, close, deep, vestiture sparse; declivital interstriae 2 much more strongly impressed and unarmed, granules on 1 and 3 distinctly larger.

Distribution.- Jalisco to Oaxaca.
MEXICO: Jalisco: 5 km NW Tequila, 19-VII-53, Bursera, S. L. Wood. Oaxaca: Totolapan, 20-V1-67, 1100 m , No. 64, Bursera, S. L. Wood.

Host.- Bursera sp.
Biology. - Specimens were taken from the bark of a cut bole 20 cm in diameter.

Notes.- The above treatment was based on the type series of 10 specimens and on 19 other specimens.

## 12. Dendroterus luteolus (Schedl)

 Fig. 196Plesiophthorus luteolus SchedI, 195I, Dusenia 2:111 (Holotype, male; Mexico; Schedl Coll.)
Dendroterus mundus Wood, 1959, Great Basin Nat. 19:3 (Holotype, male; Tehuitzingo, Puebla, Mexico; Snow Ent. Mus., Univ. Kansas); Wood, 1972, Great Basin Nat. 32:194. Synonymy
Diagnosis.- This species is distinguished from striatus (LeConte) by the smaller average size, by the different frons in both sexes, and by the stouter elytral vestiture particularly on the declivity.

Female.- Length $1.3-1.7 \mathrm{~mm}, 2.6$ times as long as wide; color light brown.

Frons with a strongly subacutely elevated, transverse carina slightly above middle, convex and coarsely punctured above, slightly, transversely impressed and finely, obscurely punctured below carina; sparsely pubescent.

Pronotum 1.2 times as long as wide; sides straight and subparallel on posterior twothirds, anterior margin rather broadly rounded and armed by about 12 coarse, low, subcontiguous teeth; summit indefinite, at center; asperities coarser on anterior third, gradually blending into granulate posterior areas of disc; posterolateral areas almost
smooth, shallowly, coarsely punctured; fine, raised lateral and posterior lines absent. Pubescence hairlike, short, suberect.

Elytra 1.5 times as long as wide; sides straight and subparallel on basal threefourths, abruptly, very broadly rounded behind; striae not impressed except l, punctures rather coarse and deep; interstriae narrower than striae, punctures in more or less uniseriate rows, very close, about half diameter of those of striae, distinctly impressed. Declivity rather steep, flattened; striae narrower than on disc, 1, 2, and part of 3 im pressed, punctures much smaller and less definite; interstriae 1 slightly elevated, 1,2 , and lower part of 3 convex, punctures subequal to those of striae and in less definite rows than on disc. Vestiture rather abundant, short; consisting of fine semierect strial hairs and slightly longer, coarser erect interstrial setae; not longer on declivity, very slightly longer on sides.

Male.-Similar to female except frons broadly convex from epistoma to vertex, rather coarsely granulate-punctate to well above eyes, vestiture inconspicuous; interstrial setae stouter, almost scalelike on declivity.

Distribution.- Nayarit to Chiapas.
MEXICO: Chiapas: Ocosingo Valley, 7-V11-50, L. J. Stannard. Morelos: Las Piedras, 17-VII-80, Bursera, T. H. Atkinson. Nayarit: Volcán Ceboruco, 5-VII-65, 1100 m, No. 188, Bursera, S. L. Wood. Puebla: 19 km SE Matamoros, 3-V1I-53, $1200 \mathrm{~m}, \mathrm{~S}$. L. Wood: Tehuitzingo, 13-V11-53, Bursera, S. L. Wood.

## Host.- Bursera spp.

Biology.- Specimens were taken from the bark of branches of two host species.

Notes.- The above treatment was based on the holotype of luteolus, on the type series of 19 specimens of mundus, and on 34 other specimens. The holotype of luteolus resembles striatus in all respects except for the sculpture of the frons, which is as in mundus. On the basis of this feature and on the indefinite type locality for luteolus, the type was associated with mundus rather than striatus. It is not impossible that these two forms eventually will be made subspecies of one another when the distributions are more fully known.

## 13. Dendroterus striatus (LeConte)

Hypothenemus striatus LeConte, 1868. Trans. Amer. Ent. Soc. 2:156 (Lectotype, female: Cape San Lucas, Baja California; Mus. Comp. Zool., 993. prsent designation)
Plesiophthorus californicus Schedl, 1952, Pan Pacif. Ent. 23:123 (Holotype, female; Angeles Bay, Gulf of California, Baja California, Mexico; California Acad. Sci.); Wood, 1972, Great Basin Nat. 32: 195. Synonymy
Diagnosis.- This species is distinguished from the very closely related luteolus Schedl by the larger average size, by the frontal differences in both sexes, and by the more slender, almost hairlike interstrial setae on the declivity.

Female.- Length $1.6-2.0 \mathrm{~mm}, 2.6$ times as long as wide; color brown.

Frons as in luteolus except transverse carina shorter, occupying half of distance between eyes; upper area less closely punctured, lower area more coarsely punctured. Interstrial setae much more slender than in luteolus, particularly on declivity.

Male.- Similar to female except frons indistinctly, transversely impressed at upper level of eyes, lower area distinctly, irregularly inflated, coarsely, subgranulately punctured.

Distribution.-S California to Baja California.

USA: California: Anza-Borrego St. Pk., 11 km S Ocotillo Wells, 11-1V-65, Bursera microphylla, C. W. O’Brien. MEXICO: Baja California: Cape San Lucas; Bahía de los Angeles, 27-V1-21, J. C. Chamberlin.

Host.- Bursera microphylla.
Biology.- Specimens were taken from the bark of limbs.

Notes.- The above treatment was based on 5 syntypes of striatus, on the holotype and 3 paratypes of californicus, and on 13 other specimens. The first syntype in the LeConte series is labeled Type No. 993; that female is here designated as the lectotype of striatus.

## Genus ARAPTUS Eichhoff

[^17]Thamnophthorus Schedl, 1938, Archiv Naturgesch. 7:174 (Type-species: Thamnophthorus volastos Schedl, subsequent designation by Blackman, 1942, Proc. U.S. Nat. Mus. 92:178); Wood, 1973, Great Basin Nat. 33:170. Synonymy
Neopityophthorus Schedl, 1938, Archiv Naturgesch. 7:180 (Type-species: Pityophthorus laetigatus Eggers, present designation); Schedl, 1951, Dusenia 2:72. Symonymy
Sphenoceros Schedt, 1939, Mitt. Münchn. Ent. Ges. 29:565 (Type-species: Sphcnoccros limax Schedl, monobasic); Wood, 1973, Great Basin Nat. 33:170. Synonymy
Diagnosis.- This genus is distinguished from Pityophthorus Eichhoff by the partly to completely septate suture 1 of the antennal club-suture 2 is never septate and all external evidence of all sutures may be absent in certain species-and by the denticles or rugae on the posterolateral margin of the protibiae that extend to the basal fourth. Most species also lack a transverse impression behind the poorly developed pronotal summit, and the transition from the asperate to the punctured area on the pronotum is gradual.

Description.- Length 1.1-2.7 mm, 2.4-3.2 times as long as wide; color yellowish brown to almost black.

Frons usually sexually dimorphic, varying in either sex from convex to elaborately excavated; greater abundance of frontal vestiture usually a female character. Eye oval, emarginate. Antennal scape elongate; funicle 5 -segmented; club small to very large, external sutures distinct to obsolete, straight to profoundly procurved, suture 1 at least partly septate in all species, 2 never septate. Pronotum usually without distinct summit, anterior slope finely asperate, transition from asperate to punctured area gradual. Scutellum
rather large, flat. Elytra usually weakly striate, declivity convex to moderately impressed, conservatively sculptured. Legs as in Pityophthorus except denticles and rugae on lateral margins extend nearer base, particularly on protibiae.

Distribution.- Nayarit and S Florida to Argentina; about 100 nominate species have been described; 53 species occur in North and Central America.

Biology.- The species are phloeophagous or spermophagous; a few evidently may adapt to either habitat. They vary from monogamous to polygamous. The males are of normal size and occur in parental galleries with the females, except in lacvigatus Eggers and costaricensis Schedl, where dwarfed, flightless males mate with sibling females in the brood host and die there. The larvae always form individual mines. Unthrifty, cut, or injured host material is usually selected for attack, including recently fallen fruit containing large seeds.

Notes.- Due to the diversity of this large genus and the unavailability of the types of many species belonging to this and similar genera, the genus is seriously in need of further study. Judging from the large number of unique specimens at hand, many species remain undescribed.

The name Neopityophthorus Schedl was originally erected for Pityophthorus insularis Eggers, P. laevigatus Eggers, P. poricollis Blandford, N. laevis Schedl, N. glabricollis Schedl, and N. eruditus Schedl, without a type-species being designated. I here designate P. laevigatus Eggers as the type-species of Neopityophthorus Schedl.

## Key to the Species of Araptus

1. Male frons moderately to profoundly excavated, median carina entirely absent except in species with major part of excavated area above upper level of eyes; female frons usually convex, with a conspicuous, low, median carina (impressed and ornamented by hair in three species, but conspicuous carina also present); elytral declivity convex to shallowly impressed2

- Male frons convex, with or without a median carina, or if impressed then impression confined to area below upper level of eyes and all cusps confined to lower margin of impression; female frons convex to rather strongly impressed, usually ornamented by hair, never with a median carina; elytral declivity convex to strongly impressed8
2(1). Male frons without a median denticle below upper level of eyes, excavation at upper level of eyes occupying less than half distance between eyes; female frons convex to weakly, transversely impressed, with a fine median carina, frontal vestiture sparse, inconspicuous; in leguminous seeds and pods
- Male frons armed by a conspicuous median denticle below upper level of eyes, excavation at upper level of eyes broad, occupying at least three-fourths of distance between eyes; female frons flattened to concave, ornamented by rather abundant hair, and by a conspicuous median carinate elevation; in vine or liana stems3

3(2). Smaller; male frons triangularly, rather strongly impressed from near epistoma to upper level of eves, armed laterally by a pair of small tubercles at bases of mandibles and laterally near its upper margin by a (usually) nontuberculate prominence; interstrial punctures on dise sparse to obsolete; Panama and Colombia to Bamaica and Surinam; 1.4-1.8 mm

1. hymenaeae (Eggers)

- Larger; male frontal excavation armed above upper level of eves by a pair of longitudinal, subcarinate cusps, unarmed by tubercles or other prominences below upper level of eyes; discal interstriae regularly punctured 4

4(3). Elytral declivity narrowly impressed at sutural striae only; female frons weakly, transversely impressed near middle; Nayarit to Guatemala; $1.8-2.4 \mathrm{~mm}$
2. fossifrons Wood

- Elytral declivity with entire width of interstriae 2 distinctly, moderately impressed; female frons not visible in material at hand; "Mexico" to Honduras; $1.6-2.1 \mathrm{~mm}$

3. deyrollei (Blandford)

5(2). Male frons transversely excavated from middle to well above eyes, its upper margin unarmed, armed on lower half at extreme lateral margins by a pair of denticles and by a stronger median denticle at same level midway between epistomal margin and upper level of eyes; female frons flattened to weakly impressed on median half from epistoma to vertex, with an obtuse median carina, and with a rather sparse brush of moderately long hair in lateral areas; discal interstriae with punctures sparse to obsolete; Jalisco to Guatemala; 2.4-2.7 mm
4. foveifrons (Schedl)

- Upper limits of male frontal excavation at vertex armed by acutely projecting margin, a conspicuous median elevatin or carina occupying two-thirds length of floor of excavation, a small tubercle at its lower end; lateral areas of male frons unarmed below upper level of eyes; female frons essentially as in male except more broadly impressed and ornamented on all margins by a fringe of very long, yellow hair; discal interstriae sparsely to regularly punctured

6(5). Upper margin of male impressed frontal area rounded on median line, lateral
cusps acute; upper margin of female frontal impression unarmed; Puebla;
$2.1-2.5 \mathrm{~mm}$

- Upper margin of male and female frontal impression acutely projecting ..... 7

7(6). Upper limits of frontal excavation armed by a continuous U-shaped costa; median frontal carina low, narrow, long, evanescent above; Jalisco to Nayarit; $1.7-2.5 \mathrm{~mm}$ 6. delicatus Wood

- Upper limits of frontal excavation armed by a median and a pair of lateral cusps; frontal carina thick, rather high, ending abruptly above; Guatemala; $2.8-3.4 \mathrm{~mm}$

7. genialis Wood

8(1). Male frons armed by a conspicuous median carina (sometimes absent in $\begin{aligned} & \text { politus) .............................................................................................................. } 9\end{aligned}$

- Male frons devoid of a median carina
$9(8)$. Body stouter, less than 2.6 times as long as wide; discal interstriae regularly punctured
- Body more slender, 2.7 or more times as long as wide; discal interstriae impunctate or with not more than one or two punctures 12
10(9). Pronotum and frons reticulate in both sexes; granules on pronotal disc minute, flat; frons minutely granulate, punctures obscure; strial punctures very fine, interstriae about six times as wide as striae; elytra glabrous; Florida and Mexico to Costa Rica, Haiti, and Jamaica; $2.0-2.5 \mathrm{~mm}$

8. politus (Blandford)

- Pronotum and frons shining in both sexes; granules on pronotal dise higher, closer; frons finely, densely punctured in both sexes; strial punctures rather coarse, interstriae less than four times as wide as striae; setae on declivity moderately long
11(10). Smaller; pronotal disc smooth, shining; punctures on declivital striae 1 and 2 almost as large as on disc, declivital surface almost smooth, brightly shining; elytral vestiture largely confined to declivity, on odd-numbered interstriae, sparse, strial setae minute to obsolete; Veracruz to Panama; $1.5-1.8 \mathrm{~mm}$ 9. tabogae (Blackman)
- Larger; pronotal dise obscurely reticulate; punctures on declivital interstriae 1 and 2 minute to obsolete, declivital surface subreticulate, rather dull; elytral vestiture reaching at least middle of disc, on all interstriae, at least twice as abundant, strial setae longer; Guatemala; 2.2 mm

10. incommodus (Blandford)

12(9). Male frontal carina not extending above upper level of eyes; female frontal vestiture less abundant, more generally distributed, shorter, longest setae extending less than one-third distance to epistoma13

- Male frontal carina extending from just below upper level of eyes to vertex; female frontal vestiture above upper level of eyes abundant, long, some setae extending more than half distance to epistoma
13(12). Body rather slender, 2.6 times as long as wide; male frontal carina extending from epistoma to upper level of eyes, low, of almost uniform height, female frons densely punctured and finely, uniformly pubescent; antennal club rather large, its width 1.2 times length of scape; strial punctures on declivity rather coarse; Veracruz to Panama; 1.7-1.9 mm

11. carinifrons (Blandford)

- Body very slender, 3.0 times as long as wide; male frontal carina much shorter, more nearly dentate, female frons granulate to subaciculate; antennal club smaller, its width equal to length of scape; strial punctures on disc small to minute
14(13). Male frons flat to feebly convex, median carina moderately strong; female
frons punctate-granulate, vestiture uniformly distributed but longer at margins;
strial punctures equally fine on disc and declivity; Veracruz to Panama;
$1.8-2.0 \mathrm{~mm} . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . ~ 12 . ~ c o n f i n i s ~(B l a n d f o r d) ~$
- Male frons rather strongly impressed, median carina very strong; female frons subaciculate, vestiture largely confined to margins; strial punctures rather coarse on disc, fine on declivity
15(14). Smaller; frons less strongly impressed in both sexes; punctures on pronotum and elytra slightly smaller; Sinaloa; $1.1-1.3 \mathrm{~mm}$

13. gracilens Wood

- Larger, frons more strongly impressed in both sexes; punctures on pronotum and elytra slightly larger; Colima and Puebla to Honduras; $1.6-1.9 \mathrm{~mm}$

14. dentifrons Wood

16(12). Female frontal vestiture long above and laterally, continuing ventrad to near bases of mandibles, central area sparsely to moderately pubescent; declivital interstrial setae in rows, longest setae half as long as distance between rows; Jalisco; Ficus; 1.4-1.7 mm 15. speciosus Wood

- Female frontal vestiture long, entirely confined to area above eyes, lower area subglabrous; elytral declivity subglabrous, setae when present minute, shorter than distance equal to diameter of a strial puncture; Costa Rica; Ficus; 1.2-1.3 mm

16. facetus Wood

17(8). Small, brightly shining species; female frons with a distinct median crest (occasionally partly carinate), almost glabrous; pronotal asperities continued laterally to base as sparse, low, discontinuous ridges; males dwarfed, incapable of flight, mate in brood gallery; antennal club small, with two weakly procurved sutures18

- Female frons with no indication of a crest or carina, usually pubescent; pronotal asperities not continued to base, or, if continued, confused, not in ridges; males equal in size to females, join females in parental tunnels; antennal club variable19

18(17). Larger, stouter, averaging 2.7 times as long as wide; frontal punctures averaging larger, deeper; color dark brown to almost black; Costa Rica and Panama to French Guiana; in fruit; females $1.5-1.7 \mathrm{~mm}$, males $1.2-1.3 \mathrm{~mm}$ 17. laevigatus (Eggers)

- $\quad$ Smaller, more slender, averaging 2.9 times as long as wide; frontal punctures smaller, obscure; color light brown; Costa Rica to Panama; in phloem; females $1.2-1.4 \mathrm{~mm}$, males 1.0 mm

18. costaricensis (Schedl)

19(17). Antennal club smaller, usually a little longer than scape, suture 1 broadly to
rather strongly procurved; if strongly procurved and club larger, then elytral
declivity impressed and usually armed by granules; setae on declivital inter-
striae nisually more slender, as long or longer than distance between rows;
elytral declivity convex or impressed ....................................................................... 20

- Antennal club larger, about twice as long as scape, suture 1 very strongly procurved or angulate, its apex at or near middle of club; elytral declivity convex, never impressed or granulate, with interstrial setae spatulate, always shorter than distance between rows49
20(19). Asperities on anterior slope of pronotum confused ..... 21
- All asperities on anterior slope of pronotum fused into four or five independent concentric rows ..... 48

21(20). Elytral declivity convex to very feebly impressed, interstriae 1 and 3 never
armed by granules ..... 22

- Elytral declivity moderately to strongly impressed, interstriae 1 and 3 armed by granules or, if absent, then either declivity strongly impressed or antennal club devoid of sutures except for strongly angulate septum or median half of suture 1

22(21). Posterior margin of abdominal sternum 5 armed by a rather strongly elevated, blunt, subtuberculate, median callus; female frons convex, pubescence short, rather sparse, a small central area smooth, shining; Nayarit to Chiapas; tree branch; 1.2-1.4 mm
19. tenellus (Schedl)

[^18]23(22). Declivital setae obsolete or length equal to less than diameter of an adjacent puncture; male frons below upper level of eyes abruptly, rather strongly, broadly impressed; declivity more evenly convex, striae 1 never impressed, interstriae 1 not elevated; frontal hair on female usually longer, more abundant24

- Declivital setae on interstriae at least equal in length to width of an interstriae,
except almost obsolete in leptus; male frons convex to shallowly impressed, if
impressed, a median callus present at upper level of eyes, callus may extend to
ward vertex; declivital striae 1 usually impressed and interstriae slightly
elevated; frontal hair in female usually shorter, less abundant
24(23). Median line in male from upper level of eyes to vertex impunctate, transversely etched; male frons rather strongly impressed below upper level of eyes, with a pair of diagonal lateral calluses midway between epistoma and upper level of eyes; punctures on declivity very small, some lines present, impressed points almost obsolete; Tamaulipas to Veracruz; 1.2-1.4 mm

20. schedli (Blackman)

- Median line from male frons to vertex with sculpture similar to adjacent areas; male frons with an epistomal callus at anterior articulation of mandible, without a submarginal callus25

25(24). Male frons moderately impressed, area above eyes reticulate, epistomal callus at anterior artification of mandible small; strial punctures on declivity minute, interstriae four to six times as wide as striae, impressed points abundant; Jalisco to Guatemala; $1.3-1.5 \mathrm{~mm}$
21. obsoletus (Blandford)

- Male frons rather strongly impressed, area above eyes smooth between punctures, lateral epistomal callus conspicuous; strial punctures on declivity rather coarse, interstriae twice as wide as striae, impressed points obsolete; Nayarit; $1.3-1.4 \mathrm{~mm}$

22. micaceus Wood

26(23). Strial punctures on basal half of disc confused, some interstrial punctures present27

- Strial punctures on disc in rows, interstrial punctures absent .................................... 29

27(26). Larger; body very stout, less than 2.0 times as long as wide; pronotum wider than long, strongly constricted on anterior third; coarse interstrial punctures almost as large as those of striae; both in recognizable rows; Panama; 2.0-2.2 mm
23. crassus Wood

- $\quad$ Smaller; body slender, at least 2.6 times as long as wide; pronotum distinctly longer than wide; punctures on elytral dise smaller; partly confused 28

28(27). Declivity evenly convex; interstrial bristles regularly placed on disc and declivity, including interstriae 2; female frons convex, sparsely marked by coarse punctures and minute points, vestiture sparse, inconspicuous; Tamaulipas; Disholcapsis gall on Quercus virginiana; 1.1-1.3 mm
24. nanulus Wood

- Declivity somewhat broadly, shallowly impressed, interstrial bristles confined to declivity, absent on 2; female frons smooth and impunctate on central third, upper third of impunctate area moderately, subcarinately, transversely elevated, marginal areas with abundant long hair; Costa Rica; tree bole; 1.8-1.9 mm
$29(26)$. Declivital interstriae 2 with a row of fine punctures (usually subgranulate) and interstrial setae as on 1 and 330
- Declivital interstriae 2 devoid of punctures and interstrial setae ..... 31

30(29). Strial punctures on disc and declivity very minute, almost obsolete; female frons planoconcave; Panama; 1.3-1.4 mm
26. teres (Blackman)

- $\quad$ Strial punctures on disc of moderate size, smaller on declivity; female frons weakly convex, a feeble median carina indicated; Veracruz to Honduras; vine; $1.5-1.8 \mathrm{~mm}$ 27. tenuis (Blackman)
31(29). Anterior margin of pronotum costiform; male frons evenly convex, without an impunctate median line above eyes; declivital interstriae 2 shallowly, distinctly impressed; Veracruz; $1.2-1.3 \mathrm{~mm}$ 28. leptus (Bright)
- Anterior margin of pronotum rather coarsely serrate; male frons with a mediancallus at upper level of eyes, an impunctate, transversely etched median lineextending to vertex; declivital interstriae 2 not impressed32
32(31). Declivity evenly convex; female frontal vestiture coarser, more abundant, evi- dently slightly longer, yellowish; Jalisco to Nayarit; Ficus, etc.; 1.4-1.7 mm

29. consobrinus Wood

- Declivital striae 1 impressed, interstriae 1 distinctly elevated: female frontal vestiture, finer, less abundant, white; Baja California; Pedialanthus macro- carpus; 1.4-I. 6 mm 30. attenuatus Wood
33(21). Antennal club solid, without external indications of sutures, median half of su- ture 1 represented by strongly angled internal septum; declivital interstriae 1 and 3 unarmed by granules ..... 34
- $\quad$ Antennal club with suture 1 clearly indicated by an external groove, if groove doubtful, then elytral declivity more strongly, more broadly impressed and interstriae 1 and 3 armed by granules ..... 36
34(33). Female frons shallowly concave on upper two-thirds, surface finely, closely punctured; discal interstriae impunctate; Veracruz to Panama; 1.8 mm

31. blanditus Wood

- Female frons flat to feebly impressed, finely granulate; discal interstriae punctured ..... 35
35(34). Minute strial hair present, interstrial setae usualy extending to elytral base; de- clivity more shallowly, narrowly impressed; Hidalgo to Ecuador; Annona, Persea seeds; $2.0-2.3 \mathrm{~mm}$ 32. sehwarzi (Blackman)
- Minute strial hair absent, interstrial setae absent except on sides; declivity more deeply, broadly impressed; Honduras; rust cones on Pinus oocarpa; $1.9-2.3 \mathrm{~mm}$ 33. sobrinus Wood
36(33). Discal interstriae regularly punctured or else all punctures on disc confused ..... 37
- Strial punctures on disc in rows, interstriae impunctate ..... 42
37(36). Suture I of antennal club septate throughout, rather weakly procurved; lower half of female frontal area finely reticulate and punctured or dull and finely granulate-punctate, central area above smooth, shining, marginal areas above and dull area below with abundant, rather long hair ..... 38
- Sutures of antennal club, if visible, very strongly procurved, mesal half of suture 1 marked by an internal septum; larger species ..... 39
38(37). Female frons reticulate, distinctly punctured, shining area near vertex poorlydeveloped, vestiture slightly finer and shorter; male frons smooth, polished,shagreened, punctures minute, sparse, glabrous except at epistoma; Costa Rica;Persea americana; 1.7-1.9 mm34. mendicus Wood
- Female frons dull, rugose-reticulate, punctures obscure; male frons sub-reticulate, more coarsely, closely punctured, at least a few short setae on lowerhalf; Costa Rica; tree branch; 1.4-1.6 mm

| 39 | Body stouter, 2.4 times as long as wide; female frons broadly, shallowly concave, densely, finely, uniformly punctured and ornamented by abundant, fine, moderately long hair; Costa Rica; vine; $1.9-2.2 \mathrm{~mm}$...................... 36. conditus Wood |
| :---: | :---: |
| - | Body more slender, at least 2.6 times as long as wide; female frons subglabrous, convex or feebly impressed, punctures larger, less abundant, less uniformly distributed $\qquad$ 40 |
| 40(39). | Smaller species; strial punctures very small, in definite rows, interstrial punctures indistinguishable from numerous, confused impressed points, elytral disc without setae except near declivity; declivital impression less abrupt, not as deep; Guatemala; 1.5 mm $\qquad$ 37. incompositus (Blandford) |
| - | Larger species; strial punctures larger, either confused with those of equal size on interstriae or interstrial punctures in clearly identifiable rows; declivital impression more abrupt, slightly deeper |

41(40). Elytral and pronotal punctures minute, shallow; rows of strial and interstrial setae extend from base to apex of elytra; frons transversely impressed in female, convex in male, shining, punctured; Costa Rica to Panama; vine; 1.9-2.2 mm

- Elytral and pronotal punctures moderately coarse, rather deep, elytra subglabrous, a few short setae on declivity and sides; frons convex, dull, rugosereticulate in both sexes, epistomal margin distinctly elevated; Costa Rica; tree branch; 1.7-2.1 mm

39. laudatus Wood

42(36). Strial punctures rather fine to minute, interstriae at least twice as wide as
striae; declivity weakly to moderately impressed; smaller species ..... 43

- Strial punctures rather coarse, interstriae as wide as striae; declivity more strongly impressed; larger species ..... 45

43(42). Posterior margin of sternum 5 armed by a median, blunt, subtuberculate prominence in both sexes; discal areas of pronotum and elytra smooth and brightly shining; female frons convex except median lower half almost flat, shining, very finely, closely punctured, vestiture fine, short; Nayarit to Panama; tree branch; $1.5-1.8 \mathrm{~mm}$ 40. eruditus (Schedl)

- Posterior margin of sternum 5 normal; pronotal dise reticulate; sculpture and
adornment of female frons different ..... 44

44(43). Elytral discal interstriae smooth, with rather sparse, minute, impressed points; female frons planoconvex, with a few rather coarse punctures, vestiture very long; Costa Rica; vine; 1.1-1.3 mm 41. vesculus Wood

- Discal interstriae with many irregular impressed lines and a few impressed points; female frons broadly, shallowly concave, very minutely, densely punctured, vestiture fine, very short; Panama; vine; 1.3-1.4 mm . 42. exigialis Wood
45(42). Male frons strongly, evenly convex; female frons weakly convex, more uniformly sculptured, vestiture extending only slightly above eyes; Guatemala; shrub; 1.9-2.3 mm
- Middle third of male frons strongly, transversely impressed; female frons more extensively flat or partly impressed, an impunctate callus on lower median area, vestiture extending well above eyes
46(45). Male frons rather strongly, transversely impressed from upper level of eyes to two-thirds distance to epistoma, lower margin of excavation a blunt, transverse carina; female frons broadly flattened, median third of lower half shining, impunctate, slightly inflated, remaining area densely punctured and ornamented by long hair; Guatemala; Menisperma; 1.6-1.8 mm

44. trepidus Wood

- Male frons below eyes rather strongly excavated to two-thirds distance to epistoma, lower margin of excavation strongly, acutely carinate except carina interrupted in median area; female frontal callus in frontalis smaller, a small, subconcave impression on upper half, more coarsely punctured
47(46). Smaller; lateral margins of elytral declivity armed by about three pairs of small denticles; anterior margin of pronotum unarmed; Guatemala; 1.6 mm 45. poricollis (Blandford)
- Larger; lateral margins of elytral declivity unarmed; anterior margin of pronotum rather coarsely serrate; Guatemala; shrub, $2.4-2.7 \mathrm{~mm}$

46. frontalis Wood

48(20). Antennal club rather small, sutures rather equally arcuate, 2 clearly marked by a row of setae; interstriae impunctate; Jalisco to Oaxaca; shrub; 1.3-1.7 mm ..... 47. concentralis (Schedl)

- Antennal club rather large, suture 1 rather strongly angulate, 2 not evident; interstriae with confused punctures; Veracruz to Honduras; 1.2-1.4 mm

48. macer (Bright)

49(19). Strial punctures on disc small to minute, in definite rows, interstriae impunctate; body more slender, more than 2.5 times as long as wide

- Discal punctures on elytra larger, confused or interstriae clearly punctured; body rather stout, less than 2.3 times as long as wide 53
50(49). Body more slender, 2.8 times as long as wide; posterior half of pronotum mostly smooth, shining; female frons convex, rugose-reticulate, finely punctured, glabrous; strial punctures small, distinct; Costa Rica; Myrica pubescens bole; $1.7-2.0 \mathrm{~mm}$

49. nigrellus Wood

- Body slender, not more than 2.6 times as long as wide; posterior half of pronotum reticulate; female frons flat, pubescent; discal strial punctures minute 51
$51(50)$. Interstrial setae on declivity sparse, spaced within a row by distances greater than length of a seta; strial hair obsolete; female frons densely, coarsely punctured, with sparse, moderately long hair; Costa Rica; Roupala complicata; $1.2-1.5 \mathrm{~mm}$

50. vinnulus Wood

- Interstrial setae on declivity close, spaced within a row by distances distinctly less than length of a seta; rows of strial hair present on declivity; female frons sparsely, finely punctured, with a dense brush of long hair 52

52(51). Declivital striae not impressed, punctures obsolete; distance from upper level of eyes to upper limits of female frontal pubescence 1.2 times distance from epistomal margin to upper level of eyes, longest setae on vertex extend twothirds distance to epistoma; Panama; Roupala; $1.7-2.2 \mathrm{~mm} . . . . . . . . . . . .51 . ~ f u r v u s ~ W o o d ~$

- Declivital striae feebly impressed, punctures minute; distance from upper level of eyes to upper limits of female frontal pubescence 1.5 times distance from epistomal margin to upper level of eyes, longest setae on vertex extend almost to epistomal margin; Guatemala; Roupala; $1.5-1.9 \mathrm{~mm}$
53(49). Anterior margin of female pronotum narrowly rounded, not at all angulate; female frons concavely impressed on median third above upper level of eyes, glabrous; Costa Rica; tree limb; 1.7-2.0 mm
- Anterior margin of female pronotum acutely angulate, ending in a sharp point; female frons broadly flattened above eyes, upper margin ornamented by a dense fringe of long hair; Nayarit to San Luis Potosí; tree limb; 1.7-2.2 mm .....

54. aztecus (Wood)

## 1. Araptus hymenaeae (Eggers) Figs. 197-198

Neodryococtes hymenacae Eggers, 1933, Mém. Trav. Lab. d'Ent. Mus. Nat. d'Hist., Nat. Paris 1(1):9 (Holotype, male; Gourdonville, French Guiana, Paris Mus.)
Neodryocoetes insularis Eggers, 1940, Arb. Morph. Taxon. Ent. Berlin-Dahlem 7:128 (Holotype, female; Guadeloupe; Fleutiaux Coll.); Wood, 1973, Great Basin Nat. 33:172. Synonymy
Neodryocoetes earihaeus Blackman, 1942, Proc. U.S. Nat. Mus. 92:185 (Holotype, female; Trinidad; U.S. Nat. Mus., 56004); Wood, 1973, Great Basin Nat. 33:172. Synonymy
Neodryococtes guianae Blackman, 1942, Proc. U.S. Nat. Mus. 92:186 (Holotype, female; British Guiana, U.S. Nat. Mus., 56003); Wood, 1973, Great Basin Nat. 33:172. Synonymy
Neodryocoetes hoodi Blackman, 1942, Proc. U.S. Nat. Mus. 92:187 (Holotype, female; Taboga 1stand, Panama; U.S. Nat. Mus., 56006); Wood, 1973, Creat Basin Nat. 33:172. Synonymy
Neodryocoetes humilis Blackman, 1942, Proc: U.S. Nat. Mus. 92:188 (Holotype, female: Bonito, Pernambuco, Brazil; UT.S. Nat. Mus., 56005); Wood, 1975, Great Basin Nat. 35:392. Synonymy

Fig. 197. Araptus spp., antennae and protibiae: 1-2, schucarii; 3-4, politus: 5, mucunae: 6, columbianus: 7. tahogae; 8-9, cubensis; 10, hostilis; 11-14, hymenacae. (After Blackman 1942:pl. 20.)

Diagnosis.- This species is distinguished from sparsipunctatus (Blackman) by the much more irregularly impressed male frons, with the tubercle at the lower lateral angle (at base of mandible) distinctly larger, and by the more closely punctured pronotum.

Male.- Length $1.4-1.8 \mathrm{~mm}, 2.6$ times as long as wide; color reddish brown.

Frons rather strongly, subconcavely impressed on a triangular area from epistoma almost to upper level of eyes, upper margins of impression rather abrupt, lower lateral angles armed by a pair of tubercles. Antennal club rather small, suture 1 strongly procurved, not reaching middle, septate throughout, suture 2 obscurely indicated.

Pronotum 1.1 times as long as wide; widest at base, sides weakly arcuate and converging slightly on basal two-thirds, rather broadly rounded in front; anterior margin finely serrate on an acute costa; summit obscure, in front of middle; asperities small, confused; posterior areas reticulate, rather coarsely, deeply, closely punctured. Glabrous.

Elytra 1.5 times as long as wide, 1.4 times as long as pronotum; sides straight and parallel on basal half, slightly tapered, then rather broadly rounded behind; striae not impressed, punctures rather small, moderately deep, in very slightly irregular rows; interstriae three times as wide as striae, smooth and shining, with numerous impressed points, punctures obsolete. Declivity rather steep, narrowly convex; striae 1 narrowly, distinctly impressed, interstriae 1 feebly elevated; strial punctures slightly smaller and deeper than on disc. Vestiture largely confined to declivity, sparse, of rather short, flattened bristles, frequently abraded.

Female- - Similar to male except weakly convex, a fine, low, median carina from epistoma to upper level of eyes; surface reticulate, punctures rather small, shallow, rather sparse; frontal vestiture sparse, inconspicuous.
Distribution.- Panama and Colombia to Jamaica and Surinam.

PANAMA: Barro Colorado 1sland, 27-X11-63, 70 m , at light, S. L. Wood: Taboga 1sland, 16-23-X-13, in plants, J. D. Hood. OTHER COUNTRIES: Colombia, Venezuela. Trinidad, British Cuiana, Surinam, Jamaica. Brazil.

Hosts.- Cajanus cajon, Cicer arietinum, Hymenaea courbaril, etc.

Biology.- Fallen seed pods of the host are selected for attack. Other host species have been reported, but the identification of specimens could not be confirmed.

Notes.- The above treatment was based on a male cotype of hymenaeae and of insularis, on the holotypes of caribaeus, guianae, and hoodi, and on 76 other specimens. The limited material available to previous authors did not reveal the extreme variability within a series in sculpture of the male frons. As a result, several synonyms were named and others will probably be found. In a single series from Jamaica the male frons varied from almost flat to strongly concave and the lateral tubercles from obscure to well developed. Other anatomical parts and the female frons are constant.

## 2. Araptus fossifrons Wood

Araptus fossifrons Wood, 1975, Creat Basin Nat. 35:30 (Holotype, male; Lago Amatitlan, Guatemala; Wood Coll.)
Diagnosis.- This species is distinguished from the distantly related hymenaeae (Eggers) by the larger size, by the stouter body form, by the presence of interstrial punctures, and by the very different male frons.

Male.- Length $1.8-2.4 \mathrm{~mm}, 2.5$ times as long as wide; color rather dark reddish brown.

Frons essentially convex, with median half strongly concave from midway between epistoma and upper level of eyes to well above eyes; surface shining, rather finely punctured; lateral angles of upper margin sharply marked by a pair of cusps, lower slope of concavity sometimes with a very weak median carina; vestiture sparse, short, inconspicuous. Antennal club moderately large, suture 1 strongly procurved, not reaching middle, marked externally throughout, its mesal half septate, suture 2 very obscure.

Pronotum 1.1 times as long as wide; widest on basal half, sides moderately arcuate, distinctly constricted on anterior half, broadly rounded in front; anterior margin armed by about 16 fine serrations; summit obscure, well in front of middle; asperities fine, confused; posterior areas smooth, shining, with numerous fine points, punctures rather coarse, deep, close, broad median line impunctate. Glabrous.

Elytra 1.5 times as long as wide, 1.5 times as long as pronotum; striae not impressed except 1 near declivity, punctures small, rather deep; interstriae about four times as wide as striae, surface smooth, shining, minute impressed points abundant, uniseriate punctures almost as large as those of striae. Declivity steep, rather broadly convex; striae 1 rather deeply, narrowly impressed, all punctures smaller than on disc, entirely devoid of granules. Vestiture usually abraded, when present consisting of minute strial hair and rows of short interstrial bristles, each bristle less than half as long as distance between rows.

Female.- Similar to male except frons convex, with a broad, shallow, transverse impression below upper level of eyes, a fine median carina from epistomal margin to upper level of eyes, surface more finely closely punctured, vestiture of rather abundant, fine, moderately long hair.

Distribution- Nayarit to Guatemala.
MESICO: Colima: 24 km W Armeria, 30-VI- $65,30 \mathrm{~m}$, No. I4I, tree seed pods. Jalisco: 8 km S Atenquique, 25 -V1-65, 1000 m , No. 96, wine seed pods, 21 km N Juchitlán. 2-VII- $65,1000 \mathrm{~m}$, vine seed pods; 24 km S Mazamitla, 22-VI-65, 2500 m , No. 99, vine seed pods; Tuxpan, 23-VI-65, 1300 m , vine seed pods. Nayarit: Los Corchos, 10-VII-65, 7 m , vine seed pods; 8 km N Ruiz, 14-VII-65, $100 \mathrm{~m}, ~ N o . ~ 245$, vine seed pods. Oaxaca: 19 km SE Oaxaca, No. 57 , vine seed pods. GUATEMALA: Lago Amatitlan, I0-VI-64, 700 m , No. 702, vine seed pods. All were taken by me.

Biology. - The mature fruiting bodies of various vines and one tree species were infested by this species.

Notes. - The above treatment was based on the type series of 124 specimens and on 36 other specimens.

## 3. Araptus deyrollei (Blandford)

Pityophthorus deyrollei Blandford, 1904, Biol. Centr. Amer., Coleopt. 4(6):245 (Lectotype, male; Mexico; British Mus. Nat. Hist., designated by Wood, 1974, Great Basin Nat. 34:278)
Araptus insinuatus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(I):4.3 (Holotype male: Guatemala; Wood Coll.); Wood, 1974, Great Basin Nat. 34:278. Synonymy
Diagnosis.- This species is distinguished from the very closely related fossifrons Wood by the strongly impressed declivital interstriae 2 , by the longer elytral vestiture, and by the more finely, more closely punctured pronotal dise.

Male.- Length $1.6-2.1 \mathrm{~mm}, 2.4$ times as long as wide; color reddish brown.

Frons aFd pronotum as in fossifrons except punctures on pronotal dise distinctly smaller, closer. Elytra as in fossifrons except discal punctures averaging larger; declivital interstriae 2 strongly, rather abruptly impressed; vestiture very slightly longer, finer than in fossifrons.

Female.- Similar to male except frons (concealed) apparently as in female foveifrons.

Distribution.- Mexico to Honduras.
MEXICO: "Mexico." GUATEMALA: Guatemalan seeds intercepted at San Pedro, California, 7-111-63. honduras: La Ceiba, Atlántida, 17-V1-49, at light, E. C. Becker.

Biology.- This species infests mature seeds.

Notes.- The above treatment was based on the lectotype of deyrollei and on the type series of five specimens of insinuatus.

## 4. Araptus foveifrons (Schedl)

Thammophthorus foccifrons Schedl, 196.3, Ent. Arb. Mus. Frey 14:161 (Holotype, male; Guadalajara, Jalisco, Mexico; Sched! Coll.)
Araptus interjectus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(I):44 (Holotype, male; Volcán de Agua, Guatemala; Wood Coll.); Wood, 1975, Great Basin Nat. 35:21. Synonymy
Diagnosis.- This species is distinguished from fossifrons Wood by the larger size, by the more elongate form, by the near absence of interstrial punctures, and by the different frons in both sexes.

Male.- Length 2.4-2.7 mm, 2.9 times as long as wide; color rather dark reddish brown.

Frons strongly, transversely impressed from eye to eye from middle to well above upper level of eyes, its margins obtuse, its lower lateral angles armed by a pair of rather coarse tubercles and with a large, pointed, median tubercle at same level; lower third of area below upper level of eyes subaciculate; all surfaces shining; vestiture sparse except along epistomal margin. Antennal club as in fossifrons.

Pronotum 1.15 times as long as wide; widest behind middle, sides moderately arcuate on more than posterior half, weakly constricted on anterior third, rather broadly rounded in front; anterior margin armed by
about eight irregular serrations; indefinite summit one-third of pronotum length from anterior margin; asperities fine, confused; posterior areas obscurely reticulate in some areas, numerous minute, impressed points present, punctures rather small, deep, moderately close. Glabrous except for a few setae on asperate area and lateral margins.
Elytra 1.7 times as long as wide, 1.7 times as long as pronotum; sides straight and parallel on basal two-thirds, broadly rounded behind; striae not impressed except 1 near declivity, punctures moderately coarse, spaced by diameter of a puncture; interstriae twice as wide as striae, shining, with rather numerous minute points and moderately abundant, subtransverse impressed lines, punctures obsolete except for an occasional puncture on some specimens. Declivity steep, broadly convex; sutural interstriae distinctly, rather abruptly elevated, 2 slightly wider than 1 or 3 and impunctate, 1 and 3 each with a few small punctures. Vestiture largely abraded, a few short interstrial bristles on declivity.

Female.- Similar to male except frons broadly flattened, weakly impressed near median line, median line with a conspicuous, blunt carina from epistoma to well above eyes; frontal vestiture of moderate abundant, fine, uniformly distributed long hair, distinctly longer at margins.

Distribution.- Jalisco to Guatemala.
MEXICO: Jalisco: Guadalajara. GUATEMALA: Volcán de Agua, 19-V-64, 1000 m , Nos. 609, 612, vine, S . L. Wood.

Biology.- Specimens were removed from pith tunnels in a recently cut vine 2 cm in diameter.

Notes.- The above treatment was based on the holotype of foveifrons and on the type series of 14 specimens of interjectus.

## 5. Araptus accinctus Wood

Araptus accinctus Wood, 1974, Brigham Young University Sci. Bull., Biol. Ser. 19(1):44 (Holotype, male; 3 km SE Acatlán, Puebla, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from fossifrons Wood by the more slender body form, by the sparse discal interstrial punctures, and by the very different frons in both sexes.

Male.- Length 2.1-2.5 mm, 2.8 times as long as wide; color dark reddish brown.

Frons excavated as in fossifrons but with lateral cusps longer, extending ventrad to upper level of eyes, a sharply elevated median carina extending from deepest point of excavation ending on epistomal margin in a small tooth, lateral margins of lower half of excavation armed by one or more pairs of small tubercles. Antennal club as in fossifrons.

Pronotum and elytra as in foceifrons (Schedl) except odd-numbered discal interstriae punctured, even-numbered interstriae very sparsely punctured, and declivity as in fossifrons except more narrowly convex, punctures smaller.

Female.-Similar to male except frons shallowly concave from eye to eye from epistoma to vertex, surface shining, finely punctured, subaciculate, a distinctly elevated median carina extending from center of excavation to denticulate epistomal margin; margins of frontal excavation ornamented by a rather dense fringe of fine, long hair.

Distribution.- Puebla.
MEXICO: Puebla: 3 km SE Acatlán, 15-Vt-67, 1500 m, No. 38, vine, S. L. Wood.

Biology.- Specimens were taken from axial pith tunnels in a recently cut vine 1 cm in diameter.

Notes.- The above treatment was based on the type series of seven specimens.

## 6. Araptus delicatus Wood

Araptus delicatus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):44 (Holotype, male; 8 km S La Huerta, Jalisco, Mexico; Wood Coll.)
Dagnosis.- This species is distinguished from genialis Wood by the smaller size, by the more slender form, and by the very different sculpture of the frons.

Male.- Length $1.7-2.5 \mathrm{~mm}, 2.8$ times as long as wide; color dark brown except basal half of elytra light brown.

Frons deeply impressed on triangular area from epistoma to vertex, upper angle of triangle on vertex an inverted U-shaped area having its margins acutely costate, floor of impressed area obscurely aciculate and with a low, long, acute carina; vestiture fine, short, moderately abundant, with a conspicuous epistomal brush. Antennal club as in fossifrons Wood.

Pronotum 1.2 times as long as wide; sides on basal half almost straight and parallel,
broadly rounded in front; anterior margin armed by about 12 low serrations; indefinite summit one-third pronotum length from anterior margin; asperities small, confused; posterior areas shining, with numerous impressed points, punctures moderately coarse, deep, close. Vestiture of moderately abundant, fine, very short hair.

Elytra 1.6 times as long as wide, 1.4 times as long as pronotum; sides straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed except 1 weakly, punctures rather small, deep, spaced by diameter of a puncture; interstriae two to three times as wide as striae, shining, marked by irregular lines, punctures almost as large as those of striae, irregularly placed. Declivity steep, broadly convex; strial and interstrial punctures smaller than on disc; sutural interstriae feebly elevated, area from striae 1 to 3 flat on middle half. Vestiture of rows of short strial and slightly longer interstrial hair, longest interstrial setae slightly shorter than distance between rows.

Female.- Similar to male except frons more extensively, subcircularly impressed, Ushaped carina as in male, vestiture on margins abundant and very long.

Distribution.- Jalisco to Nayarit.
MEXICO: Jalisco: 8 km S La Huerta, l-VII-65, 500 m . No. I6I, vine, 21 km N. Juchitlán, 2-V'II-65, I000 m, No. 188, vine. Nayarit: Laguna Santa Maria, 6-VII-65, 1000 m , No. 192, vine; Los Corchos, I0-VII-65, 7 m , No. 222, vine. All were taken by me.

Biology. - Specimens were taken from axial pith tunnels in the stems of a vine having linear leaves.

Notes.- The above treatment was based on the type series of 64 specimens and on 59 other specimens.

## 7. Araptus genialis Wood

Araptus genialis Wood, 1974. Brigham Young Univ. Sci. Bull., Biol. Ser. I9(1):45 (Holotype, male; Volcán de Aqua, Guatemala; Wood Coll.)
Diagnosis.- This species is distinguished from delicatus Wood by the larger size, by the stouter body form, and by the sculpture of the frons.

Male.- Length $2.8-3.4 \mathrm{~mm}, 2.7$ times as long as wide; color dark reddish brown.

Frons deeply, triangularly impressed on median three-fourths from epistoma to vertex, upper angle more strongly impressed, its
margin armed by one median and two lateral acutely elevated cusps; floor of impression punctate to obscurely aciculate, with a broad, strongly elevated, median carina from emarginate epistoma to deepest part of concavity, both upper and lower ends terminate abruptly. Antennal club as in fossifrons.

Pronotum 1.16 times as long as wide; as in delicatus except discal punctures smaller, not as deep.

Elytra 1.7 times as long as wide, 1.4 times as long as pronotum; as in delicatus except discal interstriae three to four times as wide as striae and declivital interstriae 3 feebly elevated.

Female.- Similar to male except frontal impression more extensive, its margins ornamented by a dense fringe of long, yellow hair.

Distribution.-Guatemala.
Guatemala: Volcán de Agua, Esquintla, 19-V-64, 1000 m . No. 609, vine, S. L. Wood.
Biology.- Specimens were taken from axial pith tumnels in stems of a cut vine.

Notes.- The above treatment was based on the type series of 20 specimens.

## 8. Araptus politus (Blandford) Fig. 197

Pityophthorus politus Blandford, 1904, Biol. Centr. Amer., Coleopt. 4(6):24 (Leetotype, male; Mexico: British Mus. Nat. Hist., present designation)
Neodryocoetes mexicanus Eggers, 1936, Rev. de Ent. 6:391 (Holotype, female; Colonia, prob. Veracruz, Mexico; deposited in but not now in Eggers Coll.): Schedl, 1938, Archiv Naturgesch. N.F., 7:177. Synonymy
Neodryocoetes hubhardi Blackman, 1942, Proc. U.S. Nat. Mus. 92:182 (Holotype, female; Kingston, Jamaica; U.S. Nat. Mus. 56000 ); Wood; 1973, Great Basin Nat. 33:173. Synonymy
Diagnosis.- This species is distinguished from tabogae (Blackman) by the larger size, by the reticulate pronotal dise, by the much smaller punctures on pronotum and elytra, and by the different frons in both sexes.

Male.- Length $2.0-2.5 \mathrm{~mm}, 2.5$ times as long as wide; color dark reddish brown.

Frons broadly convex above, distinctly, transversely impressed just above epistoma; surface reticulate, with fine obscure punctures; a low median carina extending from transverse impression to slightly above upper level of eyes, carina occasionally partly to entirely obsolete; vestiture sparse, short,
inconspicuous. Antennal club much as in foveifrons except septum of suture 1 almost complete.

Pronotum 1.07 times as long as wide; sides almost straight and parallel on basal half, distinctly constricted on anterior half, rather narrowly rounded in front; anterior margin armed by about 14 low serrations; indefinite summit at middle; asperities small, confused; posterior areas finely reticulate, punctures very small, spaced by at least two diameters of a puncture. Glabrous.

Elytra 1.5 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal two-thirds, very broadly rounded behind; striae not impressed, punctures in irregular rows, very small, rather shallow; interstriae obscurely subreticulate, about six times as wide as striae, usually with impressed points, punctures very small. Declivity rather steep, broadly convex; striae 1 distinctly impressed, interstriae 1 very weakly elevated; strial punctures deeper than on disc. Vestiture obsolete or of minute setae shorter than diameter of puncture from which they arise.

Female.- Similar to male except frontal vestiture moderately abundant, short to rather long, carina present or not.

Distribution.-Florida, Mexico to Costa Rica, Cuba, Haiti, and Jamaica.

USA: Florida: "Fla.": intercepted at Miami in bird seed. MEXICO: Veracruz: Colonia. COSTA RICA: San Isidro del General, 5-X11-63, 1000 m , No. 285, Mucuna andreana, S. L. Wood.

Hosts.-Mucuna andreana, M. fawcetti (Jamaica), Cola sp. (Haiti).

Biology. - Specimens were reared from seeds of the hosts.

Notes.- The above treatment was based on the 2 male syntypes of politus, on the holotype of hubbardi, and on 58 other specimens. The first of Blandford's 2 syntypes is labeled Type, but has never been so designated. I here designate that male as the lectotype of politus.

## 9. Araptus tabogae (Blackman) Fig. 197

Neodryococtes tabogae Blackman, 1942, Proc. U.S. Nat. Mus. 92:184 (Holotype, female; Taboga Island, Panama; U.S. Nat. Mus., 56002)
Neodryococtes vinealis Bright, 1972, Canadian Ent. 104:1667 (Holotype, female; Ejipantla, 8 km or 5
miles S San Andrés Tuxtla. Veracruz, Mexico; Canadian Nat. Coll., 12625); Wood, 1973, Great Basin Nat. 33:17.4. Synonymy
Diagnosis.- This species is distinguished from politus (Blandford) by the smaller size, by the obscurely reticulate to shining pronotal disc, by the larger pronotal and elytral punctures, and by the different frons.

Male.- Length $1.5-1.8 \mathrm{~mm}, 2.7$ times as long as wide; color dark reddish brown.

Frons convex, rather finely granulatepunctate, with an acute median carina from epistoma to vertex. Antennal club as in politus.

Pronotum 1.1 times as long as wide; outline and sculpture about as in politus except disc obscurely subreticulate, punctures rather small, deep, their lateral margins form an obscure granule, granules become obsolete laterally. Subglabrous.

Elytra 1.6 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae 1 feebly impressed, surface shining, with a few impressed points and irregular lines, punctures moderately large, deep, moderately confused, smaller toward declivity; declivity rather steep, convex; strial punctures in rows, rather small, striae 1 moderately impressed, interstriae 1 distinctly elevated, 2 feebly impressed; interstrial punctures small. Vestiture largely confined to declivity, of rather sparse rows of short interstrial bristles, all shorter than distance between rows.

Female.- Similar to male except frons flat, shining, very finely, closely, deeply punctured over broad area from epistoma to well above eyes, vestiture of abundant, fine, long yellow hair uniformly distributed, longer at margins, carina absent.

Distribution.- Veracruz to Panama.
MEXICO: Veracruz: Ejipantla, 8 km or 5 miles $S$ San Andrés Tuxtla, 5-V-69, vine, D. E. Bright. HONDURAS: Olanchito, 30-VII and 8-IX-49, at light, E. C. Becker. COSTA RICA: Cañas, Guanacaste, 13-VII-66, 50 m , No. 29. vine, S. L. Wood. PANAMA: Taboga Island, H. F. Dietz.

Biology.- Specimens were taken from axial pith tunnels of a cut vine.

Notes.- The above treatment was based on the holotypes of tabogae and vinealis, and on eight other specimens.

## 10. Araptus incommodus (Blandford)

Pityophthorus incommodus Blandford, 1904. Biol. Centr. Amer., Coleopt. 4(6):245 (Holotype, female: Cerro Zunil. Guatemala: British Mus. Nat. Hist.)
Diagnosis.- This species is distinguished from tabogae (Blackman) by the larger size, by the slightly reticulate pronotal disc and elytral declivity, by the much finer punctures on declivital striae 1 and 2 , and by the very different elytral vestiture.

Female.- Length $2.2 \mathrm{~mm}, 2.6$ times as long as wide; color reddish brown.

Frons apparently as in tabogae (obscured by card).

Pronotum as in tabogae except serrations on anterior margin smaller, irregular, disc somewhat reticulate with granules slightly larger.

Elytra as in tabogae except punctures on dise closer and apparently smaller punctures on declivital striae 1 and 2 much smaller to obsolete, vestiture on interstriae from middle of disc to apex.

Distribution.- Guatemala.
guatemala: Cerro Zunil. 4000 ft ( 1300 mm ). Champion.

Notes.- The above treatment was based on the holotype.

## 11. Araptus carinifrons (Blandford)

Pityophthorus carinifrons Blandford, 1904, Biol. Centr. Amer., Coleopt. 4(6):244 (Holotype, male; Motzorongo, Veracruz, Mexico; British Mus. Nat. Hist.)
Diagnosis.- This species is distinguished from tabogae (Blackman) by the strongly reticulate pronotal disc, by the impunctate discal interstriae, with the strial punctures in rows, and by the slightly impressed female frons.

Male.- Length $1.7-1.9 \mathrm{~mm}, 2.6$ times as long as wide; color dark reddish brown.

Frons as in tabogae except punctures larger, deeper, granules obscure. Pronotum as in tabogae except dise more strongly reticulate, granules slightly larger. Elytra as in tabogae except strial punctures on dise smaller, in rows, interstriae three to four times as wide as striae, impunctate.

Female.- Similar to male except frons as in female tabogae except very feebly concave.

Distribution.- Veracruz and Panama.
MEXICO: Veracruz: Motzorongo. PANAMA: Ft. Clayton, Canal Zone, 22-XII-63, 30 m , No. 318, vine, S. L. Wood.

Biology. - Specimens were taken from axial pith tunnels in the stems of a recently cut vine.

Notes.- The above treatment was based on the holotype and on 26 other specimens.

## 12. Araptus confinis (Blandford)

Pityophthorus confinis Blandford, 1904, Biol. Centr. Amer., Coleopt. $4(6): 241$ (Lectotype, male; Jalapa, Veracruz, Mexico; British Mus. Nat. Hist., designated by Wood, 1975, Great Basin Nat. 35:39)
Neopityophthorus glabricollis Schedl, 1938, Archiv Naturgesch. 7(2):181 (Holotype, male; Teopisca, Chiapas, Mexico; Schedl Coll.); Wood, 1975. Great Basin Nat. 35:391. Synonymy
Diagnosis.- This species is distinguished from dentifrons Wood by the smaller pronotal and elytral punctures and by the very different frons in both sexes.

Male.- Length $1.8-2.0 \mathrm{~mm}, 3.0$ times as long as wide; color dark reddish brown.

Frons almost flat on median two-thirds from epistoma to well above eyes, surface subaciculate, punctured in marginal areas, with central half bearing a sharply elevated, dentate, longitudinal carina, its highest point at its middle, a small callus on median line at vertex, vestiture of moderately abundant, fine hair. Antennal club as in politus (Blandford).

Pronotum 1.3 times as long as wide; widest just behind middle, sides weakly arcuate on posterior half, distinctly constricted on anterior half, rather narrowly rounded in front; anterior margin armed by about $10-14$ low serrations; indefinite summit slightly in front of middle; asperities small, confused; posterior area obscurely subreticulate, rather coarsely, deeply, closely punctured. Discal area glabrous.

Elytra 1.8 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, punctures in rows, small, spaced by diameter of a puncture; interstriae about three times as wide as striae, subreticulate, impunctate. Declivity steep, convex; sutural interstriae weakly elevated, 2 feebly impressed, interstriae except 2 with fine punctures; remaining sculpture as on disc. Vestiture largely confined to declivity, consisting of rows of minute strial hair and longer interstrial
bristles, bristles equal in length to distance between rows.

Female.- Similar to male except frons more broadly flattened, carina absent, vestiture abundant, uniformly distributed, longer at margins.

Distribution.- Veracruz to Panama.
MEXICO: Veracruz: Jalapa. GUATEMALA: Guatemala City, 30-V-64, 1300 m , No. 640, vine, S. L. Wood. HONDURAS: Olanchito, 19-V to 21-VI-49, at light, E. C. Becker. PANAMA: Cerro Punta, Chiriquí, 11-1-64, 1800 m , No. 395, vine, S. L. Wood.
Biology. - Specimens were taks from stems of a cut vine 1 cm in diameter.

Notes.- The above treatment was based on the lectotype of confinis, on the holotype of glabricollis, and on 17 other specimens.

## 13. Araptus gracilens Wood

Araptus gracilens Wood, 1976, Great Basin Nat. 36:364 (Holotype, male; 4 miles or 6 km N Mazatlán, Sinaloa, Mexico; Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from dentifrons Wood by the smaller size, by the less strongly impressed frons in both sexes, and by the slightly smaller punctures on the pronotum and elytra.

Male.- Length $1.1-1.3 \mathrm{~mm}, 3.2$ times as long as wide; color brown.

Frons as in dentifrons except almost flat, carina and marginal tubercles very slightly smaller.

Pronotum 1.3 times as long as wide, as in dentifrons except anterior margin more broadly rounded, punctures slightly smaller.

Elytra 1.8 times as long as wide, 1.5 times as long as pronotum; as in dentifrons except strial punctures smaller, more widely spaced.

Female.-Similar to male except frons; frons as in female dentifrons except weakly convex, vestiture finer, slightly shorter.

Distribution.-Sinaloa.
MEXICO: Sinaloa: 6 km N Mazatlán, 31-VII-64, from active oriole nest, E. E. Lindquist.

Notes.- The above treatment was based on the type series of four specimens.

## 14. Araptus dentifrons Wood

Breviophthorus mexicanus Schedl, 196:3 (nec Eggers, 1936), Ent. Arb. Mus. Frey 14:161 (Holotype, male; Mexico; Schedl Coll.). Probable synonym
Araptus dentifrons Wood, 1974. Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):45 (Holotype, male: 3 km SE Acatlán, Puebla, Mexico; Wood Coll.)

Diagnosis.- This species is distinguished from confinis (Blandford) by the impressed male frons, with the carina much stronger, and with a series of small tubercles arming the lateral and dorsal margins of the impressed area, by the different female frons, and by the coarser elytral punctures.

Male.- Length $1.6-1.9 \mathrm{~mm}, 3.0$ times as long as wide; color very dark reddish brown.

Frons subconcavely impressed to upper level of eyes, with median area on lower half very strongly produced into a short, dentate, median carina, upper and lateral margins of impressed area armed by a row of about nine tubercles; surface shining, subaciculate near epistoma; vestiture sparse, inconspicuous except on epistoma.

Pronotum as in confinis except posterior areas with numerous impressed points (obscurely reticulate in some specimens), punctures coarse, deep. Elytra as in confinis except discal surface smooth, shining, with impressed points, strial punctures larger, interstriae less than twice as wide as striae, declivital punctures strongly reduced in size, almost obsolete.

Female.- Similar to male except frons flattened, very shallowly concave on median third, with an obscure median impressed line below, a weak carina above, marginal areas subgranulate, not tuberculate, vestiture rather uniformly distributed but more abundant and longer on margins.

Distribution.-Colima and Puebla to Honduras.

MEXICO: Jalisco: Vokcán Colima, 23-VI- $65,2500 \mathrm{~m}$, No. 104, vine, S. L. Wood. Puebla: 3 km SE Acatlán, $15-$ VI-67, 1500 m , No. 38, vine, S. L. Wood. HONDURAS: Olanchito, 21-VI-49, at light, E. C. Becker.

Biology.-Specimens were taken from axial pith tunnels in a cut vine.

Notes.- The above treatment was based on the type series of 32 specimens.

The male holotype of Breviophthorus mexicanus Schedl ( $1.8 \mathrm{~mm}, 3.1$ times as long as wide) is very similar to dentifrons and may be the same species. Schedl's specimen is more slender, the spaces between the punctures on the pronotal disc are smooth, and the strial punctures on the elytral declivity are more strongly impressed. A female paratype of dentifrons in the Volcan Colima series almost matches these characters; that
specimen intergrades within its series with normal specimens of dentifrons. A specimen from Texas (Hidalgo Co., 22-III-60, J. N. Knull) in the Canadian National Collection probably is of this species.

## 15. Araptus speciosus Wood

Araptus speciosus 1980, Great Basin Nat. 40:357 (Holotype, female; 8 km S La Huerta, Jalisco, Mexico; Wood Coll.)
This species is distinguished from facetus Wood by the larger size, by the longer elytral vestiture, and by the different ornamentation of the female frons. Pityophthorus exquisitus (Blackman) has the female frons less broadly flattened, the frontal setae shorter, the pronotum more reticulate and more coarsely punctured, and the elytral setae slightly longer.

Female.- Length $1.4-1.7 \mathrm{~mm}, 2.7$ times as long as wide; color dark reddish brown.

Frons broadly flattened from epistoma to vertex, shining, finely, closely punctured, sparsely pubescent at center, densely ornamented by long, yellow hair at sides and above, longest setae on vertex extend twothirds distance to epistoma.

Pronotum 1.1 times as long as wide; widest slightly behind middle; sides on posterior half weakly arcuate, feebly constricted on anterior half, then rather narrowly rounded in front; anterior margin armed by 4 to 10 serrations; summit poorly developed, slightly in front of middle; asperities on anterior slope moderately large, arranged into discontinuous, irregular, subconcentric rows, posterior areas mostly smooth, shining, some specimens with very obscure indications of reticulation, punctures moderately coarse, deep, rather close. Glabrous.

Elytra 1.7 times as long as wide, 1.5 times as long as pronotum; sides straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, punctures rather small, moderately deep; interstriae about twice as wide as striae, almost smooth, shining, impunctate, impressed points not clearly visible. Declivity steep, rather broadly convex; sutural interstriae feebly elevated; strial punctures smaller than on disc, a few very small interstrial punctures also present. Vestiture confined to declivity,
consisting of a few interstrial bristles, each almost as long as distance between rows.

Distribution.- Jalisco.
MEXICO: Jalisco: 8 km S La Huerta, $1-\mathrm{VII}-65,500 \mathrm{~m}$. No. 168, Ficus, S. L. W'ood.

Hosts.- Ficus sp.
Biology.- Specimens were taken from axial pith tunnels in twigs 2 cm in diameter.

Notes.- The above treatment was based on the type series of nine specimens.

## 16. Araptus facetus Wood

Araptus facetus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(I):46 (Holotype, female; Río Tempisque, Guanacaste, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from exquisitus (Blackman) by the smaller size, by the shorter or obsolete elytral vestiture, and by the ornamentation of the female frons.

Male.- Length $1.2-1.4 \mathrm{~mm}, 2.5$ times as long as wide; color reddish brown.

Frons, pronotum, and elytra as in exquisitus except elytra glabrous or setae very minute.
Female.- Similar to male except frons shallowly concave from eye to eye from epistoma to vertex, surface smooth, impunctate on lower fourth, finely punctured above, vestiture confined to area above eyes, consisting of a dense brush of long, yellow hair.

Distribution.- Costa Rica.
COSTA RICA: Río Tempisque, Guanacaste, 25-III-64, 15 m , No. 501, Ficus, S. L. Wood.
Biology. - Specimens were taken from small broken branches of a native fig tree.
Notes.- The above treatment was based on the type series of four specimens.

## 17. Araptus laevigatus (Eggers)

Pityophthorus laevigatus Eggers, 1933, Mém. Trav. Lab. d'Ent. Mus. Nat. d'Hist. Nat., Paris 1(1):6 (Holotype, female; St. Laurent du Maroni, French Guiana; Paris Mus.)
Neopityophthorus insularis Eggers, 1940, Arb. Morph. Taxon. Ent. Berlin-Dahlem 7:130 (Holotype, female; Trois Rivières, Guadeloupe; deposited in but not now in Eggers Coll.); Wood, 1973, Great Basin Nat. 33:173. Synonymy
Neodryocoetes guadeloupensis Schedl, 1951, Dusenia 2:73 (Replacement name); Wood, 1973, Great Ba$\sin$ Nat. 33:173. Synonymy
Diagnosis.- This species and the next present a radical biological departure from
the remainder of the genus (see below). It is distinguished from costaricensis (Schedl) by the larger size, by the stouter body form, and by the very slightly larger, deeper punctures on the frons. The males are dwarfed, flightless, and rare.

Female.- Length $1.5-1.7 \mathrm{~mm}, 2.7$ times as long as wide; color very dark brown.

Frons broadly convex, with an obtuse, subcarinate median crest form epistoma to upper level of eyes; surface smooth, shining, punctures varying from small to rather large, moderately deep; vestiture of sparse, inconspicuous hair. Antennal club small, sutures weakly arcuate, 1 septate.

Pronotum 1.17 times as long as wide; widest at base, sides feebly arcuate on more than basal half, rather broadly rounded in front; anterior margin armed by about 12 serrations, indefinite summit about one-third pronotum length from anterior margin; asperities on anterior slope small, confused; posterior area smooth, brightly shining, with low, longitudinal asperities continued as sparse discontinuous ridges almost to base, punctures and points almost totally absent.

Elytra 1.6 times as long as wide, 1.5 times as long as pronotum; sides straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, punctures small, spaced within a row by two to four diameters of a puncture; interstriae smooth, briçhtly shining, obsolescent points obscurely indicated, impunctate, two to four times as wide as striae. Declivity rather steep, convex; one or more striae sometimes narrowly impressed; interstriae with a few minute punctures. Vestiture of sparse interstrial bristles on odd-numbered interstriae, almost as long as distance between rows, more widely spaced within a row.

Male.- Length 1.2-1.3 mm, similar to female except metathoracic wings shorter than elytra; rare.

Distribution.- Costa Rica and Panama to French Guiana.

COSTA RICA: San Isidro del General, San José, 13-XIl-63, 1000 m , No. 309, Daphnopsis seibertii seeds, S. L. Wood; Pandora, Limon, 23-VIII-63, 50 m , No. 139, Cynometra hemitomophylla seeds, S. L. Wood; Rincón de Osa, Puntarenas, 11-VIII-66, 30 m , S. L. Wood; Dominical, Puntarenas, 9-XIl-63, 3 m , No. 294, legume seed pod, S. L. Wood. PANAMA: Barro Colorado Island, Canal Zone, 27-XIl-63, 70 m , No. 346, Entada gigas
seeds, S. L. Wood. OTHER COUNTRIES: Guadeloupe, French Guiana, Surinam.

Hosts.- Cynometra hemitomophylla, Daphnopsis seibertii and Entada gigas.

Biology.- Specimens were taken from the fallen fruits and seeds of the hosts.

The males are dwarfed and, because the flight wings are of reduced size, they are incapable of flight. Consequently, mating occurs in the brood chambers and only the female enters new host material.

Notes.- The above treatment was based on a cotype of laevigatus and one of insularis, and on 61 other specimens.

## 18. Araptus costaricensis (Schedl)

Neopityophthorus insularis var. costaricensis Schedl, 1938, Archiv Naturgesch. 7:180) (Syntypes, females; Costa Rica: Schedl Coll.)
Diagnosis. - This species is distinguished, with difficulty, from laevigatus Eggers by the smaller size, by the more slender form, by the smaller, shallow frontal punctures, and by the phloeophagous habit.

Female.- Length 1.2-1.4 mm, 2.9 times as long as wide; color light brown.

Exactly as in laevigatus except as noted in the diagnosis.

Male.- Length 1.0 mm ; similar to female except flight wings shorter than elytra.

Distribution.- Costa Rica to Panama.
COSTA RICA: Río Damitas, Dota Mts., San José, 22-VIII-63, 250 m , No. 122, Cccropia petiole, S. L. Wood: Turrialba, Cartago, 1970, I. R. Gara. PANAMA: Barro Colorado Island, Canal Zone, 27-XIl-63. 70 m, No. 338, tree limb, S. L. Wood.

Biology.- Specimens were taken from the phloem tissues of a limb 10 cm in diameter and from the petiole of a fallen Cecropia leaf.

Notes. - The above treatment was based on one male and 22 females, one of which was compared directly to Schedl's syntypes. An occasional specimen in this series has the same exact form and structure as laevigatus except for the much smaller size. Although it probably represents a valid species, its status should be verified through field studies.

## 19. Araptus tenellus (Schedl)

Neodryocoetes tenellus Schedl, 1951, Dusenia 2:109 (Holotype, male; Chiapas, Mexico; Schedl Coll.) Ctenyophthorus mexicanus Schedl, 1963, Ent. Arb. Mus. Frey 14:162 (Holotype, female; Trampaluz,

Escárcega, Campeche, Mexico; Schedl Coll.); Wood, 1975, Great Basin Nat. 35:392. Synonymy Neodryocoetes granulatus Schedl, 1964, Reichenbachia 3:311 (Replacement name for Ctenyophthorus mexicanus Schedl)
Araptus cuspidis Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):46 (Holotype, female; 8 km E San Blas, Nayarit, Mexico; Wood Coll.); Wood, 1975, Great Basin Nat. 35:392. Synonymy
Diagnosis.- This species and eruditus (Schedl) have a conspicuous median process at the posterior margin of abdominal sternum 5 that distinguishes them from all other species in the genus. This species is distinguished from cuspidatus by the convex, unarmed elytral declivity and by the different female frons.

Male.- Length $1.2-1.4 \mathrm{~mm}, 2.6$ times as long as wide; color yellowish brown.

Frons convex, shining, surface obscurely, rather coarsely punctured. Antennal club rather small, subcircular, sutures rather strongly procurved, 1 extending one-third, 2 two-thirds club length from base, 1 finely septate.

Pronotum 1.0 times as long as wide; widest on basal third, sides moderately arcuate, converging toward rather narrowly rounded anterior margin; anterior margin armed by about 12 low serrations; summit definite, very slightly in front of middle; asperities moderately coarse, confused; posterior areas strongly reticulate, punctures small, obscure. Glabrous.

Elytra 1.5 times as long as wide; 1.6 times as long as pronotum; sides straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, punctures small, distinct; interstriae three times as wide as striae, almost smooth, impressed points rather obscure, impunctate. Declivity steep, convex; sutural interstriae feebly elevated, 2 indistinctly impressed; strial and interstrial punctures minute, almost obsolete. Vestiture largely confined to declivity, of interstrial rows of slender bristles, each slightly longer than distance between rows, similarly spaced within a row. Sternum 5 with a conspicuous median elevation on posterior margin.

Female.- Similar to male except frons shining, convex, slightly flattened on median half below upper level of eyes, this area punctured on its lateral and upper margins,
smooth and shining in central area, punctured area with moderately abundant, short, inconspicuous hair.

Distribution.- Nayarit to Chiapas.
MEXICO: Campeche: Trampaluz. Chiapas: Lazardo Cárdenas. Nayarit: 8 km E San Blas, 12-V11-65, 70 m , No. 233, tree branch, S. L. Wood.

Biology.-Specimens were taken from a broken branch of an unidentified tree.

Notes.- The above treatment was based on the holotypes of tenellus, mexicanus, and cuspidus and on 15 other specimens.

Araptus pallidus (Blackman) $\quad(?=$ pororicensis Schedl) is a distinct species having abdominal sternum 5 as in tenellus.

## 20. Araptus schedli (Blackman)

Fig. 198

Neodryocoetes schedli Blackman, 1942, Proc. U.S. Nat. Mus. 92:195 (Holotype, male; Tampico, México; U.S. Nat. Mus., 55976)

Neodryocoetes lenis Blackman, 1942, Proc. U.S. Nat. Mus. 92:198 (Holotype, male; Cordoba, Veracruz, Mexico; U.S. Nat. Mus., 55979); Wood, 1975, Great Basin Nat. 35:392. Synonymy
Diagnosis.- This species is distinguished from micaceus Wood by the very different male frons and by the much smaller punctures on the elytral declivity.

Male.- Length 1.2-1.4 mm, 2.7 times as long as wide; color dark brown.

Frons rather abruptly, strongly, transversely impressed from epistoma to upper level of eyes; upper area convex, coarsely punctured except median line impunctate and transversely etched; surface of impressed area smooth, shining, punctures almost obsolete, lateral areas with a short, conspicuously subcarinate, diagonal callus extending from near epistomal margin toward dorsomedian part of eye; epistomal margin broadly, rather deeply emarginate; vestiture confined to epistomal margin. Antennal club 1.2 times as long as wide, 1.5 times as long as scape; sutures 1 and 2 strongly procurved, dividing club into about equal thirds.

Pronotum 1.1 times as long as wide; widest on basal third, sides feebly arcuate, gradually converging toward rather narrowly rounded anterior margin; anterior margin finely, broadly serrate; summit at middle; posterior areas smooth, shining, surface with numerous impressed points, punctures moderately
coarse, deep, spaced by one to two diameters of a puncture. Glabrous except at lateral margins.

Elytra 1.7 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, punctures slightly larger and very slightly confused on basal half of disc; interstriae shining, almost smooth, weak lines and obscure impressed points evident, about three to four times as wide as striae. Declivity rather steep, convex; striae not impressed, punctures minute, a few similar interstrial punctures on lower third confused with those of striae. Strial and interstrial setae minute to obsolete, never longer than distance equal to diameter of a puncture.

Female.-Similar to male except frons flattened and pubescent (concealed in specimens at hand).

Distribution.- Tamaulipas to Veracruz.
MEXICO: Tamaulipas: Tampico, 26-X11-09, E. A. Schwarz. Veracruz: Cordoba, 23-IV-08, A. Fenyes. Mexican seeds intercepted at New York, 20-XI-45, 46-2193.

Notes.- The above treatment was based on the holotypes of schedli and lenis and on eight other specimens.

## 21. Araptus obsoletus (Blandford)

Pityophthorus obsoletus Blandford, 1904, Biol. Centr. Amer., Coleopt. 4(6):242 (Holotype, female; Las Mercedes, Guatemala; British Mus. Nat. Hist.)
Diagnosis.- This species is distinguished from placatus Wood by the smaller size, by the more coarsely punctured male frons, by the longer, more abundant female frontal hair, and by the more simple elytral declivity.

Male.- Length 1.3-1.5 mm, 2.6 times as long as wide; color dark brown.

Frons convex, a shallow, broad transverse impression from upper level of eyes to epistoma; surface shining, coarsely, closely, deeply punctured; vestiture fine, sparse, inconspicuous. Antennal club comparatively small, suture 1 rather weakly procurved, septate, 2 almost obsolete.

Pronotum 1.17 times as long as wide; as in tenellus (Schedl) except posterior area weakly reticulate, punctures coarse, deep, rather close. Glabrous.

Elytra 1.7 times as long as wide, 1.6 times as long as pronotum; as in tenellus except declivity uniformly convex, densely covered by impressed points, strial punctures sometimes more distinct. Elytra either glabrous or with minute setae shorter than diameter of punctures from which they arise.

Female.-Similar to male except frons broadly flattened from epistoma to vertex, rather coarsely, closely punctured, with abundant, long, yellow hair.

Distribution.- Jalisco to Guatemala.
MEXICO: Jalisco: 33 km N Juchitlán, 3-VII-65, 1300 m, No. 177, Ficus, S. L. Wood. GUATEMALA: Las Mercedes, G. C. Champion; Lago Amatitlan, 10-V1-64, 700 m . No. 703 , vine, S. L. Wood.

Biology.- Specimens were taken from transverse tumnels in the phloem.

Notes. - The above treatment was based on the female holotype and on 38 other specimens.

## 22. Araptus micaceus Wood

Araptus micaceus Wood, 1975, Great Basin Nat. 35:29 (Holotype, male; Los Corchos, Nayarit, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from obsoletus (Blandford) by the strongly impressed frons, with a pair of epistomal calluses at the anterior articulations of the mandibles, by the smooth surface between punctures on the area above the eyes, and by the coarser strial punctures on the declivity.

Male.- Length $1.3-1.4 \mathrm{~mm}, 2.6$ times as long as wide; color light brown.

Frons as in obsoletus except much more strongly impressed, punctures in impressed area smaller, surface on area above eyes reticulate; epistomal calluses at anterior articulation of mandibles much larger.

Pronotum as in obsoletus except serrations on anterior margin much smaller (margin subcostate) and reticulation on posterior areas more strongly impressed.

Elytra as in obsoletus except strial punctures much larger, interstriae one and onehalf times as wide as striae on disc, about twice as wide on declivity; impressed points obsolete on declivity.

Female.-Similar to male except frons planoconvex on median two-thirds from level of antennal insertion to slightly above eyes, finely, closely punctured except impunctate
on median line to upper level of eyes, punctured area bearing fine, rather long, moderately abundant hair; hair shorter, less abundant and covering a smaller area than in female obsoletus.

Distribution.- Nayarit.
MEXICO: Nayarit: Los Corchos, 10-VII-65, 7 m , No. 222 , vine. S. L. Wood.

Notes.- The above treatment was based on the type series of nine specimens.

## 23. Araptus crassus Wood

Araptus crassus Wood, 1977, Great Basin Nat. 37:211 (Holotype, female?; 8 km NE Cerro Jefe, Panama Prov., Panama; Canadian Nat. Coll.)
Diagnosis.- This species represents a unique group in the genus that is characterized by the very stout body form that has the general habitus of Coccotrypes, by the similar frons in both sexes, by the shallow, equally large strial and interstrial punctures, by the unique antennal club, and by the broad tibiae.

Female(?).- Length 2.0-2.2 mm, 1.9 times as long as wide; color dark brown.

Frons evenly convex, surface smooth, shining, a few very minute, isolated granules; epistomal margin with a weak, narrow, median suggestion of a premandibular lobe. Antennal club obovate, about as long as scape, about 1.15 times as long as wide, about equally divided by rather strongly procurved sutures 1 and 2 , these weakly grooved and marked by rows of setae, suture 1 septate on lateral half.

Pronotum 0.94 times as long as wide; widest near base, sides strongly arcuate on basal half, rather strongly constricted, then narrowly rounded in front; anterior margin armed by about four, small, indefinite granules; summit indefinite, on basal third; anterior slope rather gradual, armed by low, isolated, abundant asperities, extending to base in lateral areas, surface between asperities shining, almost smooth; posterior areas shining, not smooth, punctures very fine, indefinite, sparse. Vestiture of short, fine, recumbent hair.

Elytra about 1.01 times as long as wide; 1.2 times as long as pronotum; sides straight and parallel on basal half, very broadly rounded behind; striae not impressed, punctures moderately large, distinctly impressed,
spaced by diameter of a puncture; interstriae smooth, shining, almost three times as wide as striae, punctures as large as those of striae, a bit more widely spaced. Declivity broadly convex, very steep; sculpture as on disc. Vestiture of minute strial hair, length of each less than diameter of its puncture, and erect, flattened, narrowly spatulate, closely set interstrial setae, each equal in length to about two-thirds distance between rows.

Sexual differences not apparent, although both sexes apparently represented.

Distribution.- Panama.
panama: 8 km NE Cerro Jefe, Panama, 27-Ill-76, 700 m, H. P. Stockwell.

Notes.- The above treatment was based on the type series of five specimens.

## 24. Araptus nanulus Wood

Araptus nanulus Wood, 1973, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):54 (Holotype, female; Tampico, Tamaulipas, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from others in the genus by the small size, by the simple, unadorned frons in both sexes, by the greatly reduced, almost obsolete strial punctures, by the regular, almost scalelike interstrial bristles, and by other characters.

Female.- Length 1.1-1.3 mm, 2.6 times as long as wide; color dark reddish brown.

Frons convex, feebly impressed just above epistoma in lateral areas; surface shining, rather coarsely, sparsely punctured and with more numerous minute points; vestiture fine, sparse, inconspicuous. Antennal club oval, as long as scape, sutures almost straight, suture 1 finely septate.

Pronotum 1.06 times as long as wide; widest near base, sides weakly arcuate on basal half, feebly constricted on anterior half, rather narrowly rounded in front; anterior margin serrate, about 12 indistinct serrations; summit indistinct; crenulations on anterior slope rather coarse, continued as low, irregular transverse costae to well behind summit; posterior areas shining, with numerous impressed points, appearing almost subgranulate in lateral areas. Vestiture erect, moderately abundant, somewhat similar to elytral setae.

Elytra 1.6 times as long as wide, 1.5 times as long as pronotum; striae not impressed, minute punctures almost obsolete; interstriae
shining, setiferous punctures confused, with numerous impressed points of almost equal size. Declivity rather narrowly convex; interstriae 1 shallowly impressed; surface sculpture as on disc. Vestiture of interstrial rows of suberect apically flattened bristles; each bristle about as long as distance between rows, somewhat more closely spaced within a row.

Male.-Similar to female in all respects.
Distribution.-Tamaulipas.
MEXICO: Tamaulipas: Tampico, 14-VIII-72, Disholcapsis gall on Quercus tirginiana, G. F. Frankie.

Notes.- The above treatment was based on the type series of 14 specimens.

## 25. Araptus decorulus Wood

Araptus decorus Wood, 1974 (nee Bright. 1972), Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):47 (Holotype, female; Rincón de Osa, Puntarenas. Costa Rica; Wood Coll.)
Araptus decorulus Wood, 1974, Great Basin Nat. 34:278 (Rcplacement name)
Diagnosis.- This unique species is distinguished by the shallow declivital impression, confused elytral punctures, slender form and fine sculpture, and by the very different female frons.

Male.- Length $1.8-1.9 \mathrm{~mm}, 2.8$ times as long as wide; color yellowish brown.

Frons convex, except weakly flattened on central half below upper level of eyes, a small callus near upper margin of flattened area, a pair of calluses in ventrolateral parts of this area; surface shining, rather finely punctured except impunctate in median area on lower half; vestiture fine, sparse, inconspicuous. Antennal club oval, sutures moderately procurved, suture 1 weakly septate.

Pronotum 1.25 times as long as wide; about as in placatus Wood except median serrations on anterior margin distinctly larger, and posterior area reticulate, dull, punctures moderately fine, deep, rather widely spaced. Glabrous.

Elytra 1.6 times as long as wide, 1.3 times as long as pronotum; outline as in placatus; surface shining, with minute points, punctures confused, rather small, moderately close. Declivity moderately steep, shallowly impressed, almost flat on median half; strial punctures in rows; interstriae 1 weakly elevated, 2 distinctly impressed; interstrial
punctures fine. Vestiture confined to declivity, consisting of rows of sparse, stout bristles except absent on 2 , bristles spaced in all directions by distances slightly greater than length of a bristle.

Female.- Similar to male except frons flattened almost from eye to eye from epistoma to vertex, with an elevated, transverse, obtuse summit just below upper level of eyes, area from summit to epistoma on median third smooth, shining, impunctate, remaining area punctured and ornamented by rather abundant, long, yellow hair.

Distribution.- Costa Rica.
COSTA RICA: Rincón de Osa, Puntarenas, 1l-VIII66, 30 m , No. 64, unidentified los, S. L. Wood.

Biology. - Specimens were taken from phloem tissues of a cut $\log 20 \mathrm{~cm}$ in diameter.

Notes.- The above treatment was based on the type series of nine specimens.

## 26. Araptus teres (Blackman)

Fig. 198

Neodryocoetes teres Blackman, 1942, Proc. U.S. Nat. Mus. 92:190 (Holotype, female; Paraíso, Canal Zone, Panama; U.S. Nat. Mus., 56007)
Diagnosis.- This species is distinguished from placatus Wood by the smaller size, by the very minute elytral punctures, and by the different female frons.

Female.- Length $1.3-1.4 \mathrm{~mm}, 2.7$ times as long as wide; color dark brown.

Frons flat, perhaps very feebly concave (not visible above eyes); shining, densely, very finely punctured, small median area on lower third impunctate; vestiture of fine, uniformly, moderately abundant, rather short hair (about as in placatus), apparently little if any longer on margins.

Pronotum 1.03 times as long as wide; about as in placatus except punctures slightly smaller.

Elytra 1.65 times as long as wide; as in placatus except strial punctures very minute, shallow; interstriae six or more times as wide as striae; surface with many fine irregular lines; declivital sculpture as on dise, some punctures apparently obsolete. Vestiture largely abraded, apparently confined to declivity, slightly longer and finer than in placatus.

Male. Similar to female except frons weakly concave, with a weak, median carina indicated.

Distribution.- Panama.
PANAMA: Paraiso, Canal Zone, 19 and 26-I-11, E. A. Schwarz.

Notes.- The above treatment was based on the holotype and allotype.

27. Araptus tenuis (Blackman)<br>Fig. 198

Neodryocoete's tenuis Blackman, 1942, Proc. U.S. Nat. Mus. 92:197 (Holotype, female: Tampico, Mexico; U.S. Nat. Mns.)
Araptus placatus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(I):46 (Holotype, male; 5 km W Jáltipan. Veracruz, Mexico; Wood Coll.). Neu synonymy
Diagnosis.- This species is distinguished from obsoletus (Blandford) by the larger size, by the more strongly impressed, more finely punctured male frons, by the short, sparse female frontal vestiture, by the elytral vestiture, and by other characters.

Male.-Length $1.5-1.8 \mathrm{~mm}, 2.8$ times as long as wide; color dark brown.

Frons broadly impressed from epistoma to upper level of eyes, upper limits attaining a distinct summit on median half; surface shining, rather finely, deeply, closely punctured; an obscure, median carina sometimes present; vestiture fine, sparse, inconspicuous. Antennal club as in obsoletus.

Pronotum 1.13 times as long as wide; widest just behind middle, sides weakly arcuate, rather broadly rounded in front; anterior margin armed by about $10-12$ low serrations; indefinite summit one-third pronotum length from anterior margin; asperities small, confused; posterior areas smooth to obscurely reticulate, punctures rather fine, moderately close. Glabrous.

Elytra 1.7 times as long as wide, 1.6 times as long as pronotum; sides straight and parallel on more than basal two-thirds, rather broadly rounded behind; striae not impressed except 1 near declivity, punctures small, spaced within row by twice diameter of a puncture; interstriae almost smooth, subshining, about four times as wide as striae, impunctate. Declivity steep, rather broadly convex; striae 1 distinctly impressed, interstriae 1 distinctly elevated, 2 weakly
impressed, interstrial punctures minute. Vestiture confined to declivity, of rows of stout, blunt interstrial bristles, each slightly shorter than distance between rows, similarly spaced within a row.

Female.- Similar to male except planoconvex, a median callus on lower half, area at upper level of eyes not elevated, surface shining, rather finely, closely punctured, vestiture very fine, moderately abundant, rather short.

Distribution.- Veracruz.
MEXICO: Veracruz: 5 km W Jáltipan, $25-\mathrm{VI}-67,50$ m, No. 117, vine, S. L. Wood. HONDURAS: La Ceiba, VI-49, at light, E. C. Becker.

Biology.- Specimens were taken from the hollow central axis of a recently cut vine.

Notes.- The above treatment was based on the type series of 43 specimens.

## 28. Araptus leptus (Bright)

Neodryocoetes leptus Bright, 1972, Canadian Ent. 104:1666 (Holotype, female; Ejipantla, 8 km or 5 miles S San Andrés Tuxtla, Veracruz, Mexico: Canadian Nat. Coll., 12624)
Diagnosis.- This species is distinguished from micaceus Wood by the convex male frons, without epistomal calluses, by the much finer pronotal and elytral punctures, and by the more strongly impressed declivital interstriae 2.

Male.- Length $1.2-1.3 \mathrm{~mm}, 2.8$ times as long as wide; color light brown.

Frons almost uniformly convex, with epistomal margin slightly elevated; surface reticulate, punctures small, shallow, rather close; vestiture sparse, short, inconspicuous.

Pronotum 1.15 times as long as wide; basic outline and anterior margin as in micaceus; posterior areas subreticulate, impressed points moderately abundant, punctures small, shallow, rather numerous, spaced by about two to four diameters of a puncture.

Elytra 1.6 times as long as wide, 1.5 times as long as pronotum; outline as in micaceus; striae 1 near declivity weakly, others not impressed, punctures very small, spaced by one to two diameters; interstriae smooth, shining, with rather numerous minute lines and impressed points, punctures obsolete, about four times as wide as striae. Declivity steep, convex; strial punctures reduced, obscure; surface shining, minutely irregular, impressed
points abundant; interstriae 1 weakly elevated, 2 shallowly impressed, lateral convexities about as high as 1 . Vestiture of minute strial setae and an occasional short interstrial hair; none of these longer than distance equal to two or three diameters of a strial puncture.

Female.-Similar to male except frons broadly, shallowly concave from epistoma to well above eyes, very densely, minutely punctured over entire impressed area, vestiture minute pile in impressed area, margins with a dense fringe of long hair.

Distribution.- Veracruz.
MEXICO: Veracruz: Ejipantla, 8 km S San Andrés Tuxtla, 5-V-69, D. E. Bright.
Notes. - The above treatment was based on a male and a female paratype. The holotype was also examined.

## 29. Araptus consobrinus Wood

Araptus consobrinus Wood, I975, Great Basin Nat. 35:394 (Holotype, male; 6 km or 4 miles W Tepic, Nayarit, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from attenuatus Wood by the evenly convex elytral declivity (attenuatus has striae 1 im pressed and interstriae 1 weakly elevated), and, on the female frons, by the coarser, more abundant, longer, yellowish vestiture.

Male.- Length $1.4-1.7 \mathrm{~mm}, 2.7$ times as long as wide; color very dark brown.

Frons similar to attenuatus except more nearly convex, punctures not as coarse, no indications of aciculation, median callus at upper level of eyes smaller, less strongly elevated.

Pronotum as in attenuatus except anterior margin armed by about eight serrations.

Elytra as in attenuatus except surface less brightly shining, strial punctures slightly larger. Declivity more evenly convex, punctures much smaller; striae 1 not impressed, interstriae 1 not elevated.
Female.- Similar to male, though frons much as in female attenuatus except frontal hair much more abundant, coarser, slightly longer, yellowish in color.

Distribution.- Jalisco to Nayarit.
MExICO: Jalisco: 33 km N Juchitlán, 3-VII-65, 1300 m, No. 177, Ficus, S. L. Wood. Nayarit: 6 km W Tepic, 13-VII-65, 1000 m , No. 241, shrub, S. L. Wood.

Notes. - The above treatment was based on the type series of 29 specimens.

## 30. Araptus attenuatus Wood

Araptus attenuatus Wood, 1975, Great Basin Nat. 35:30 (Holotype, female; 48 km W Bajía de los Angeles, Baja California, Mexico; Wood Coll.)
Diagnosis. - This species is distinguished from placatus Wood by the much coarser strial punctures, by the much longer female frontal vestiture, and by other characters cited below.

Female.- Length 1.4-1.6 mm, 3.0 times as long as wide; color dark brown.

Frons feebly convex, flattened on median half in some specimens; subshining, rather finely, closely punctured in peripheral areas, central area minutely irregular, often with a few punctures; a weak median carina on lower half; vestiture of fine, long, white, subplumose setae in punctured area at sides and above, longest setae equal in length to twothirds diameter of frons, shorter toward epistoma.

Pronotum 1.2 times as long as wide; as in placatus except anterior margin more narrowly rounded, posterior areas more distinctly reticulate, with punctures almost twice as large; minute setae present on disc.
Elytra 1.8 times as long as wide, 1.6 times as long as pronotum; similar to placatus except strial punctures almost twice as large, declivity more narrowly convex, interstriae 2 not impressed, 1 more feebly elevated. Minute strial setae visible on posterior half of disc and declivity except 1 and 2 , interstrial setae confined to declivity, absent on 2 , similar to placatus except usually finer.

Male.- Similar to female except frons more distinctly convex, punctures subrugose, obscurely aciculate, a distinct, subtuberculate, median prominence at upper level of eyes and continuing toward vertex, its summit transversely etched.
Distribution.- Baja California.
MEXICO: Baja California Norte: 48 km W Bajía de los Angeles, 3I-III-74, Hopk. 58650, M. M. Furniss; 32 km N Punta Prieta, 29-III-73, Pedialanthus macrocarpus, J. Doyen.

Notes. - The above treatment was based on the type series of 28 specimens.

## 31. Araptus blanditus Wood

[^19]Diagnosts.- This species is distinguished from schwarzi (Blackman) by the smaller size, by the impunctate interstriae, and by the more deeply concave, more finely punctured female frons, with longer, more abundant frontal vestiture.

Female- Length $1.8 \mathrm{~mm}, 2.6$ times as long as wide; color very dark reddish brown.

Frons moderately concave on central twothirds from distinctly elevated epistoma to slightly above eyes; surface smooth, shining, very finely, closely, uniformly granulatepunctate; vestiture of uniformly distributed, rather abundant, fine, long hair, marginal setae distinctly larger. Antennal club oval, external sutures obsolete, internal septum of anterior half of suture 1 conspicuous.

Pronotum 1.1 times as long as wide; widest on basal third, sides on basal half moderately arcuate, distinctly constricted on anterior half, rather broadly rounded in front; anterior margin armed by about 12 low serrations; broad summit near middle; asperities rather small, confused; posterior areas smooth, shining, impressed points very small, moderately abundant, punctures rather coarse, deep, moderately close. Glabrous.
Elytra 1.55 times as long as wide, 1.65 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind; striae 1 moderately, others not impressed, punctures moderately large, deep, very close, rows slightly irregular; interstriae smooth, shining, points obscure to absent, impunctate. Declivity moderately steep, convex, shallowly sulcate; sutural striae narrowly impressed, interstriae 2 moderately impressed, ascending laterally, 3 higher than suture; strial punctures slightly smaller than on disc; interstrial punctures small, obsolete on 2. Vestiture largely confined to declivity, in interstrial rows except obsolete on 2 , of moderately stout bristles, each as long as distance between rows, similarly spaced within a row.

Distribution.- Veracruz.
MEXICO: Veracruz: Fortin de las Flores, 22-V-65, at light, D. Rabago. PANAMA: Volcan Chiriquí, 11-I-64, tree branch, S. L. Wood.

Notes. - The above treatment was based on the holotype and on 35 other specimens.
32. Araptus schwarzi (Blackman)

Fig. 197
Thamnophthorus schwarzi Blackman, 1942, Proc. U.S. Nat. Mus. 92:178 (Holotype, female; Boquete, Panama; U.S. Nat. Mus., 55998)
Diagnosis.- This species is distinguished from blanditus Wood as indicated in the above key and in the diagnosis of that species.

Female.- Length $2.0-2.3 \mathrm{~mm}, 2.3$ times as long as wide; color dark reddish brown.

Frons broadly, subconcavely impressed from conspicuously elevated, broad epistomal process to well above eyes; surface shining, closely, finely, uniformly subgranulately punctured; vestiture of moderately abundant, very fine, short hair. Antennal club as in blanditus Wood.

Pronotum 1.0 times as long as wide; widest on basal third, sides on posterior half moderately arcuate, distinctly constricted on anterior half, rather narrowly rounded in front; anterior margin subserrate; indefinite summit well behind middle; asperities moderately coarse, confused; posterior area almost smooth, punctures rather coarse, deep, close. Vestiture of moderately abundant, fine, short hair.

Elytra 1.5 times as long as wide, 1.5 times as long as pronotum; sides straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed except 1 toward declivity, punctures confused toward base, in almost regular rows posteriorly; interstriae smooth, about twice as wide as striae, with few to regularly placed punctures. Declivity rather steep, convex, shallowly sulcate; interstriae 1 distinctly elevated, 2 distinctly impressed, 3 broadly rounded, as high as 1 ; striae 1 and 2 distinctly impressed, punctures in rows, smaller than on disc; interstrial punctures fine. Vestiture of rows of fine, short, strial hair, and distinctly longer, fine, interstrial hair, longest setae averaging about two-thirds distance between rows.

Male. - Similar to female except frons weakly convex, almost smooth, punctures slightly larger, less abundant, vestiture much less abundant; anterior margin of pronotum more coarsely serrate, armed by $10-12$ serrations.

Distribution.- Hidalgo to Ecuador.

MEXICO: Hidalgo: 17 km NE Jacala, 22-VI-53, 1700 m , in flight, S. L. Wood. Quintana Roo: "Quintana Roo," Aguacate. COSTA RICA: San José, San José, 6-V14, intercepted at New York. Also intercepted at Laredo, Texas, in Annona cherimola from Mexico. OTHER COUNTRIES: Ecuador.

Hosts.- Annona cherimola, Persea americana.

Biology. - Specimens were taken in flight in a pine-oak forest and in the seeds of the above host plants.

Notes.- The above treatment was based on the holotype and on 73 other specimens.

## 33. Araptus sobrinus Wood

Araptus sobrinus Wood, 1974, Great Basin Nat. 34:287 (Holotype, female; Siquatepec, Honduras: Wood Coll.)
Diagnosis.- This species is distinguished from schwarzi (Blackman) by the weakly convex, more sparsely punctured female frons, by the different elytral vestiture, and by the more deeply, more broadly sulcate declivity.

Female.- Length $1.9-2.3 \mathrm{~mm}, 2.5$ times as long as wide; color reddish brown.

Frons weakly convex; surface almost smooth, punctures fine, moderately abundant; vestiture of fine, short, moderately abundant hair; frons about as in male schwarzi except for epistomal area.

Pronotum about as in schwarzi, except dise with more numerous impressed points and punctures slightly larger and more nearly circular (punctures in schwarzi oval to crescent shaped).

Elytra as in schwarzi except with abundant impressed points (usually absent in schwarzi), declivity more deeply, more broadly impressed, and vestiture greatly reduced. Strial setae entirely absent, interstrial setae rare on disc, sparse on declivity except at sides. (In schwarzi interstrial rows of erect setae usually extend to elytral base and small strial hairs occur on disc and declivity.)

Male.-Similar to female, except frons more strongly convex above, slightly impressed on lower half; epistoma broadly, shallowly emarginate about as in male schwarzi.

Distribution.- Honduras.
HONDURAS: Siguatepec, 25-V-72, Pinus oocarpa rust cones, R. Billings.

Notes.- The above treatment was based on the type series of 12 specimens.

## 34. Araptus mendicus Wood

> Araptus mendicus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. $19(\mathrm{I}): 54$ (Holotype, female: Cartago, Cartago, Costa Rica; Wood Coll.)

Diagnosis. - This species is distinguished from medialis Wood by the smooth, polished male frons, with much finer, less abundant punctures, by the finely reticulate, much more distinctly punctured female frons, with the pubescence slightly less abundant, finer, and shorter, and by the larger size.

Female.- Length $1.7-1.9 \mathrm{~mm}, 2.8$ times as long as wide; color rather dark reddish brown.

Frons broadly, evenly convex, reticulate and finely, distinctly, closely punctured on lower two-thirds, almost smooth and shining in small area above eyes; vestiture fine, moderately long, rather abundant, distinctly longer on margins, particularly above, shining area above eyes subglabrous. Antennal club about as in medialis except slightly wider.

Pronotum and elytra as in medialis.
Male.-Similar to male medialis except frons glabrous, smooth, polished, shagreened, punctures much smaller, less abundant.

Distribution. - Costa Rica.
COSTA RICA: Cartago, Cartago, Xi-65. Persea americana, N. L. H. Krauss.
Notes.- The above treatment was based on the type series of 24 specimens.

## 35. Araptus medialis Wood

Araptus medialis Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. I9(1):48 (Holotype, female; San Isidro del General, San José, Costa Rica, Wood Coll.)
Diagnosis.- This species is distinguished by the impressed elytral declivity, by the confused punctures on the elytral disc, and by the very different female frons.

Male.- Length $1.4-1.6 \mathrm{~mm}, 2.5$ times as long as wide; color yellowish brown.

Frons convex, a weak median callus at upper level of eyes; surface subshining, punctures small, shallow, rather close; vestiture fine, sparse, inconspicuous. Antennal club small, oval, suture 1 weakly procurved, septate throughout, 2 very obscure.

Pronotum 1.1 times as long as wide; widest on posterior half, sides feebly arcuate on posterior half, then distinctly constricted, rather narrowly rounded in front; anterior margin
armed by 10 coarse serrations; summit rather broad, at middle; asperities rather coarse, confusd; posterior areas shining, almost smooth to subreticulate, impressed points rather obscure, punctures fine, not sharply impressed, rather sparse. Glabrous.

Elytra 1.5 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on slightly less than basal two-thirds, rather broadly rounded behind; striae not impressed, punctures rather small, confused on more than basal half of disc, in rows posteriorly; surface shining, with numerous impressed points. Declivity rather steep, strongly sulcate; strial punctures in rows, small, rather obscure; interstriae 1 weakly elevated, 2 impressed, rather abruptly, moderately elevated laterally, lateral margins rounded, distinctly higher than suture, interstriae 1 and 3 each bearing a row of small granules. Vestiture confined to declivity, consisting of rows of stout, blunt, interstrial bristles (except absent on 2), each bristle distinctly longer than distance between rows, similarly spaced within a row.

Female.- Similar to male except 2.7 times as long as wide, frons flattened almost from eve to eye from epistoma to vertex, area below eyes dull, densely, finely punctured, central area above eyes smooth, shining, impunctate, entire lower area and marginal areas above bearing abundant, long, yellow hair, longest on upper margin; hair on elytral declivity finer and longer.

Distribution.- Costa Rica.
COSTA RICA: San Isidro del General, San José, 5-XLI-63, I 000 m , No. 288, tree branch, S. L. Wood.

Biology.- Specimens were taken from radiate tunnels in the cambium region of a broken branch.

Notes.- The above treatment was based on the type series of 23 specimens.

## 36. Araptus conditus Wood

Araptus conditus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. I9(I):48 (Holotype, female; Puerto Viejo, Heredia, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from medialis Wood by the larger size, by the absence of the lateral half of the septum of suture 1 on the antennal club, by the coarser punctures on the pronotum and elytra, and by the very different frons in both sexes.

Male.- Length 1.9-2.2 mm, 2.4 times as long as wide; color yellowish brown.

Frons broadly, transversely impressed from epistoma to upper level of eyes, a rounded median summit at its upper limits; surface smooth, finely, very closely, uniformly punctured; vestiture of rather abundant, fine, short, semirecumbent hair. Antennal club moderately large, subcircular, suture 1 strongly subangulate, its median half septate, suture 2 almost obsolete.

Pronotum 1.12 times as long as wide; sides feebly arcuate and almost parallel on basal half, slightly constricted anteriorly, rather narrowly rounded in front; anterior margin acute, subserrate; summit indefinite, at middle; asperities fine, confused, covering anterior two-thirds; posterior areas shining, obscurely reticulate, punctures moderately coarse, close, deep. Glabrous.

Elytra 1.4 times as long as wide, 1.26 times as long as pronotum; outline and disc as in medialis except striae 1 impressed, punctures rather coarse, deep. Declivity steep, bisulcate; interstriae 1 moderately elevated, 2 rather strongly impressed, narrowly above, broadly below, lateral areas rather strongly elevated, rounded, higher than suture, 1 and 3 each with a sparse row of granules; punctures in rows, rather small, shallow. Vestiture largely confined to declivity, of interstrial rows (absent on 2) of short, coarse bristles, each almost as long as distance between rows, similarly spaced within a row.

Female.-Similar to male except frons shallowly, evenly concave from eye to eye from epistoma to vertex, densely, finely, uniformly punctured, covered by abundant erect, short, yellow hair of uniform length except slightly longer at margins.

Distribution.- Costa Rica.
COSTA RICA: Puerto Viejo, Heredia, 12-II1-64, 70 m , No. 478, vine, S. L. Wood; Turrialba, Cartago, 1970, R. I. Gara.

Biology.- Specimens were taken from radiate galleries in the cambium of a woody vine.

Notes.- The above treatment was based on the type series of 17 specimens.

## 37. Araptus incompositus (Blandford)

Pityophthorus incompositus Blandford, 1904, Biol. Centr. Amer., Coleopt. 4(6):243 (Holotype, female: Coatepeque, Guatemala)

Araptus incompositus: Bright, 1976, Great Basin Nat. 36:426
Diagnosis.- This species is distinguished from frugalis Wood and laudatus Wood by the smaller size, by the more slender body form, by the less strongly impressed declivity, and by the smaller punctures on the elytral disc.

Female.-Length $1.5 \mathrm{~mm}, 2.9$ times as long as wide; color reddish brown.

Frons weakly convex, smooth, punctures fine, rather abundant, margin not elevated; vestiture fine, short, inconspicuous.

Pronotum 1.2 times as long as wide; widest near base, sides on basal half very feebly arcuate, rather narrowly rounded in front; anterior margin armed by about 12 low serrations; summit anterior to middle; asperities on anterior slope confused; posterior areas obscurely subreticulate, punctures rather small, moderately abundant.

Elytra 1.6 times as long as wide, 1.3 times as long as pronotum; outline about as in laudatus; striae not impressed, punctures very fine; interstriae at least four times as wide as striae; smooth, shining, punctures, if present, indistinguishable from numerous, confused, impressed points. Declivity steep, shallowly bisulcate; striae 1 and 2 of fine tubercles, 2 moderately impressed, slightly wider than 1 , almost flat, with numerous impressed points, shining, 3 as high as 1 , rather broadly convex, armed as on 1. Vestiture confined to declivity and basal area, consisting of moderately long, rather stout setae in closely set interstrial rows except absent on 2.

Distribution.-Guatemala.
GUATEMALA: Coatepeque, 1300 ft . Champion.
Notes.- The above treatment was based on the holotype.

## 38. Araptus frugalis Wood

Araptus frugalis Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):49 (Holotype, female; Rincón de Osa, Puntarenas, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from conditus Wood by the minute pronotal and elytral punctures, by the much more abundant elytral vestiture, by the glabrous female frons, and by the antennal club.

Female.- Length $1.9-2.2 \mathrm{~mm}, 2.7$ times as long as wide; color yellowish brown.

Frons essentially as in male conditus except more brightly polished, less closely punctured, subglabrous, with a definite median tubercle at upper level of eyes. Antennal club elongate-oval, mesal half of suture 1 represented by a longitudinal septum, extending one-third of club length from base, 2 indicated externally, profoundly procurved, extending three-fourths of club length from base.

Pronotum 1.2 times as long as wide; about as in conditus except summit distinctly anterior to middle, anterior margin armed by 18 rather coarse serrations, posterior areas with punctures much smaller. Vestiture of moderately abundant fine, short hair.

Elytra 1.5 times as long as wide, 1.3 times as long as pronotum; outline as in conditus; striae not impressed, punctures very fine, mostly in rows; interstriae four or more times as wide as striae, shining, with impressed points and very fine, irregular lines, punctures as small or smaller than those of striae, in rows. Declivity steep, sulcate; essentially as in conditus except punctures on striae 1 and 2 obsolete, others minute. Vestiture of rows of minute strial hair, and longer, rather fine, interstrial bristles on dise and declivity, bristles about as long as distance between rows, similarly spaced within a row, absent on declivital interstriae 2.

Male. - Similar to female except frons convex, rather coarsely, closely punctured, median area weakly elevated and impunctate; elytral bristles slightly longer, stouter.

Distribution.- Costa Rica.
COSTA RICA: Rincón de Osa, Puntarenas, ll-VIII66, 30 m , No. 80 , vine, S. L. Wood. PANAMA: Canal Zone, VIII, Busck.

Biology.-Specimens were taken from a cut vine 2 cm in diameter.

Notes.- The above treatment was based on the type series of 38 specimens.

## 39. Araptus laudatus Wood

Araptus laudatus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(I):49 (Holotype, female; San Isidro del Ceneral, San José, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from frugalis Wood by the narrow, convex frons in both sexes, with a distinct impression
just above the epistoma in the female, by the more narrowly, deeply sulcate elytral declivity, and by the subtriangular antennal club.

Female.- Length $1.7-2.1 \mathrm{~mm}, 2.8$ times as long as wide; color reddish brown.

Frons convex except lower third rather strongly, transversely impressed; epistoma with median area distinctly elevated; surface dull, reticulate, rather coarsely, somewhat obscurely punctured; glabrous. Antennal club subtriangular, apex somewhat pointed; mesal half of suture 1 septate, sutures not indicated externally.

Pronotum 1.2 times as long as wide; sides almost straight and parallel on be.sal half, rather narrowly rounded in front; anterior margin armed by $10-12$ low serrations; summit rather indefinite, one-third pronotum length from anterior margin; asperities rather fine, confused; posterior areas smooth, shining, with numerous impressed points, punctures rather small, moderately close. Glabrous.

Elytra 1.8 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel, then slightly tapered, bisinuately truncate on median half behind; striae not impressed; all punctures rather small, confused; surface smooth, shining, with minute impressed points. Declivity narrow, stcep, broadly, rather deeply sulcate; interstriae distinctly elevated, 2 impressed, lateral areas abruptly, strongly elevated, rounded, armed on inner margin by a series of two to six small denticles, 1 usually with one or more small granules on basal half; punctures on striae 1 and 2 obscure to obsolete. Vestiture largely confined to declivity, consisting of a few short, interstrial bristles.

Male. - Similar to female except frons more evenly convex, transverse impression almost obsolete, punctures coarser, deeper; serrations on anterior margin of pronotum larger; declivital sulcus deeper, more abrupt, sutural interstriae more regularly granulate.

Distribution.- Costa Rica.
costa rica: San Isidro del General, San José, 13-XII-63, $1000 \mathrm{~m}, \mathrm{No}$. 313, tree branch, S. L. Wood.

Biology.- Specimens were taken from radiate galleries in the cambium region of a tree branch. From two to nine females were associated with each male.

Notes.- The above treatment was based on the type series of 50 specimens.

## 40. Araptus eruditus (Schedl)

 Fig. 198Neopityophthorus cruditus Schedl, 1938, Archiv Naturgesch., n.f., 7(2): 182 (Holotype, female; El Cora, Tepic, Mexico; Schedl Coll.) Neodryocoetes buscki Blackman, 1942, Proc. U.S. Nat. Mus. 92:192 (Holotype, female; Cabima. Panama: U.S. Nat. Mus., 56008); Wood, 1975, Great Basin Nat. 35:392. Synonymy
Diagnosis.- The elevation on abdominal sternum 5 suggests a much closer relationship to tenellus Schedl than to other similar species having an impressed and granulate elytral declivity. The abdominal elevation and impressed declivity distinguish it from all other members of the genus.

Female.- Length $1.5-1.8 \mathrm{~mm}, 2.7$ times as long as wide; color yellowish brown.

Fig. 198. Araptus, Spermophthorus, Pityophthorus spp., antennae and protibiae: 15, A. eruditus; 16, A. teres; 17, A. pallidus; 18, 20, 22, A. schedli; 19, A. hymenaeae; 21, 21a, A. exquisitus; 23, A. temuis; 24-25, S. caesalpiniae; 26-27, P. pudens; 28, P. robai. (After Blackman 1942:pl. 21.)

Frons weakly convex, epistoma very slightly elevated; surface shining, punctures fine, close, rather shallow; vestiture inconspicuous, of fine, very short, moderately abundant hair. Antennal club rather small, subcircular, sutures strongly arcuate, suture 1 party septate, 2 obscure, not attaining middle of club.

Pronotum 1.15 times as long as wide; sides almost straight and parallel on basal half, broadly rounded in front; anterior margin costate, feebly serrate; summit rather indefinite, in front of middle; asperities small, confused, confined to anterior half; posterior areas smooth, shining, a few impressed points, punctures rather fine, moderately sparse, deep. Glabrous.

Elytra 1.6 times as long as wide, 1.5 times as long as pronotum; sides straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed except I near declivity, punctures moderately coarse, spaced by diameter of a puncture; interstriae smooth, shining, impunctate, about one and one-half times as wide as striae. Declivity moderately steep, sulcate; strial punctures small, almost obsolete; interstriae 1 moderately elevated, 2 impressed, 3 as high as 1 , rounded, 1 and 3 each armed by a row of about four to six granules. Vestiture mostly confined to declivity, of sparse rows of fine interstrial setae except 2 glabrous, each about as long as distance between rows.

Male. - Similar to female except frons more convex above, a feeble impression below, punctures larger, rather sparse, subglabrous.

Distribution.- Oaxaca to Panama.
MEXICO: Chiapas: 32 km N Huixtla. Nayarit: Tepic. Oaxaca: Tuxtepec, 14-X1-37. HONDURAS: La Ceiba, Atlántida, 15-V to 28-VI-49, at light, E. C. Becker; Olanchito, Yoro, 19-V, 30-V11-49, at light, E. C. Becker. Guatemala: Intercepted at San Pedro, California, in logs imported from Guatemala. COSTA RICA: Finca Gromaco on Río Coto Brus, Puntarenas, 14-Vil-63, 500 m. No. 87, tree limb, S. L. Wood; Moravia, Cartago, 11-III-64, 500 m, No. 47.4, log, S. L. Wood. PANAMA: Barro Colorado Island, Canal Zone, 16-IV-67, at light.

Biology.- Specimens were taken from radiate tunnels in the phloem of cut limbs and logs $15-25 \mathrm{~cm}$ in diameter.

Notes.- The above treatment was based on the holotypes of eruditus and buscki, and on 56 other specimens. The holotype of
eruditus is a female, not a male as originally stated.

## 41. Araptus vesculus Wood

Araptus cesculus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):50 (Holotype, female; Guápiles, Limón, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from exigialis Wood by the smoother elytral surface and by the very different frons, particularly in the female.
Female. - Length 1.1-1.3 mm, 2.5 times as long as wide; color very dark reddish brown.

Frons almost flat, median line above eves weakly elevated, epistomal margin rather weakly elevated medially; surface reticulate, punctures rather coarse, close, sparsely punctured toward center; vestiture of rather sparse, very long hair. Antennal club subcircular, suture 1 moderately procurved. weakly septate, 2 obscure.

Pronotum 1.1 times as long as wide; as in eruditus (Schedl) except posterior areas shining, weakly reticulate, punctures fine, shallow, rather widely spaced. Almost glabrous.

Elytra 1.5 times as long as wide, 1.4 times as long as pronotum; outline as in eruditus; striae not impressed, punctures fine, deep, interstriae almost smooth, shining, twice as wide as striae, impressed points almost obsolete, impunctate. Declivity steep, sulcate; essentially as in eruditus. Vestiture as in eruditus except less abundant.

Male.- Similar to female except frons more distinctly, more evenly convex, punctures coarser, more evenly distributed, almost glabrous.

Distribution.- Costa Rica.
COSTA RICA: Guápiles, Limón, 22-VIII-66, 100 m , No. 121, vine, S. L. Wood.

Biology.-Specimens were taken from a cut vine.

Notes.- The above treatment was based on the type series of four specimens.

## 42. Araptus exigialis Wood

Araptus exigialis Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(I):50 (Holotype, female; Ft. Clayton, Canal Zone, Panama; Wood Coll.)
Diagnosis.- This species is distinguished from vesculus Wood by the more abundant, more conspicuously impressed lines on the
elytral dise, by the more slender form, and by the different frons in both sexes.

Female.- Length $1.3-1.4 \mathrm{~mm}, 2.7$ times as long as wide; color reddish brown.

Frons shallowly, broadly concave from epistoma to above upper level of eyes; surface shining, minutely, densely, uniformly punctured; vestiture of fine, very short, abundant hair, very slightly longer on margins. Antennal club as in vesculus.

Pronotum 1.2 times as long as wide; as in vesculus except posterior areas very finely, rather strongly reticulate, punctures very fine, shallow, rather sparse. Glabrous.

Elytra 1.7 times as long as wide, 1.4 times as long as pronotum; as in vesculus except discal surface with points and fine, irregular lines.

Male. - Similar to female except frons strongly convex, weakly impressed along upper margin of epistoma; surface reticulate, punctures rather coarse, close, shallow, vestiture fine, short, sparse, inconspicuous.

Distribution.- Panama.
PANAMA: Ft. Clayton, Canal Zone, 22-X1l-63, 30 m , No. 318, cut vine, S. L. Wood.

Biology.- Specimens were taken from radiate tunnels just below the surface of woody tissues in a cut vine.

Notes.- The above treatment was based on the type series of 12 specimens.

## 43. Araptus refertus Wood

Araptus refertus Wood. 197., Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):51 (Holotype, female; Volcán Zunil, Guatemala, Wood Coll.)
Diagnosis.- This species is distinguished from the preceding members of this genus by the much coarser strial punctures, with impunctate discal interstriae, by the rather strongly bisulcate elytral declivity, and by the frons in both sexes.

Female.- Length 1.9-2.3 mm, 2.8 times as long as wide; color light brown (mature color probably dark brown).

Frons broadly, weakly convex; surface shining, smooth and impunctate on triangular area on lower, median half, finely, closely, rather deeply punctured on lateral and upper areas; vestiture of rather abundant, moderately long, fine hair. Antennal club oval, suture 1 moderately procurved, septate, not
reaching middle of club, suture 2 virtually obsolete, near apical margin.

Pronotum 1.13 times as long as wide; as in vesculus Wood except posterior area smooth, shining, with numerous impressed points, punctures moderately coarse, deep, close. Glabrous.

Elytra 1.7 times as long as wide, 1.5 times as long as pronotum; sides straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, punctures coarse, deep, close; interstriae as wide as striae, smooth, shining, with moderately numerous impressed points, impunctate. Declivity steep, broadly, rather strongly bisulcate; strial punctures impressed, slightly smaller than on disc; interstriae 1 moderately, gradually elevated, 2 rather strongly impressed, flat, narrow at base, rather broadly expanded on middle half, 3 rather abruptly, moderately elevated, 1 and 3 each armed on basal half by about three very small, pointed, semirecumbent denticles; a few punctures on lower half. Vestiture sparse, hairlike, mostly on or near declivity.

Male.-Similar to female except frons strongly, evenly convex; surface shining, rather coarsely, deeply, closely punctured, subglabrous except on and near epistoma; elytral declivity more strongly impressed, denticles slightly larger.

Distribution.-Guatemala.
GUATEMALA: Volcán Zunil, Quezaltenango, 27-V64.1000 m . No. 625 , shrub, S. L. W'ood.

Biology.- Specimens were taken from radiate tumnels in a Compositae shrub.

Notes.- The above treatment was based on the type series of 18 specimens.

## 44. Araptus trepidus Wood

Araptus trepidus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):51 (Holotype, female; Volcán de Agua, Guatemala; Wood Coll.)
Diagnosis.- This species is distinguished from the closely allied poricollis (Blandford) by the absence of declivital denticles and by the almost continuous transverse epistomal elevation in the male.

Female.- Length $1.6-1.8 \mathrm{~mm}, 2.7$ times as long as wide; color dark reddish brown.

Frons broadly flattened from epistoma to vertex, median third of lower half smooth, shining, distinctly elevated, remaining area
densely, finely, deeply punctured; vestiture on punctured area abundant, fine, rather long, uniformly distributed.

Pronotum 1.15 times as long as wide; as in refertus Wood except median line of posterior area impunctate.

Elytra 1.6 times as long as wide, 1.5 times as long as pronotum; outline and dise as in refertus except impressed points obscure to obsolete. Declivity steep, bisulcate; interstriae 1 abruptly, distinctly elevated, 2 rather strongly impressed, flat, wider than 1 or 3,3 abruptly, moderately elevated, 1 and 3 finely punctured, not granulate; strial punctures small, rather obscure. Vestiture of rows of very minute strial hair, and longer, slender interstrial bristles on disc and declivity, each slightly longer than distance betwen rows, similarly spaced within a row.

Male.- Similar to female except frons strongly convex on upper half, strongly, transversely impressed just below middle, lower margins of impressed area elevated laterally, elevations continue to a weak median subcarinate elevation dividing impression; upper area of frons coarsely, deeply punctured, vestiture sparse except for epistomal brush.

Distribution.-Guatemala.
GUATEMALA: Volcán de Agua, Esquintla, 19-V-64, 1000 m , No. 608, Menisperma sp., S. L. Wood.

Biology.- Specimens were taken from stems of Mcnisperma sp. less than 1 cm in diameter.

Notes.- The above treatment was based on the type series of 58 specimens.

## 45. Araptus poricollis (Blandford)

Pityophthorus poricollis Blandford, 1904, Biol. Centr. Amer., Coleopt. 4(6):238. (Holotype, male; Cerro Zunil, Quezaltenango, Guatemala; British Mus. Nat. Hist.)
Diagnosis.- This species is distinguished from frontalis Wood by the smaller size, by the unarmed anterior margin of the pronotum, and by the presence of tubercles on the lateral margins of the declivity.

Male.- Length $1.6 \mathrm{~mm}, 2.7$ times as long as wide; color reddish brown.

Frons of type above carina largely concealed by pronotum; carina as in frontalis. Pronotum and elytra as in frontalis except lateral margin of declivity armed by three tubercles.

Distribution.-Guatemala.
GUATEMALA: Cerro Zunil, Quezaltenango. 1300 m , G. C. Champion.

Notes. - The above treatment was based on the holotype.

## 46. Araptus frontalis Wood

Araptus frontalis Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):52 (Holotype, female; Volcan Zunil, Quezaltenango. Guatemala; Wood Coll.)
Diagnosis. - This species is distinguished from trepidus Wood by the larger size, by the punctured declivital interstriae 2 , and by the different frons in both sexes.
Female.- Length $2.4-2.7 \mathrm{~mm}, 2.8$ times as long as wide; color dark reddish brown.

Frons broadly flattened from epistoma to vertex, weakly concave on small median area above eyes, weakly convex on small, median impunctate area on lower half; surface shining, finely, closely, deeply punctured; vestiture of moderately abundant, fine, long hair. Antenna as in trepidus.

Pronotum 1.1 times as long as wide; essentially as in trepidus.

Elytral outline and disc as in trepidus except interstriae near declivity with punctures. Declivity about as in trepidus and refertus except interstriae 2 with a row of punctures as coarse as those of striae; lateral margins without granules. Vestiture confined to declivity, of fine, sparse hair.

Male.-Similar to female except frons deeply, transversely concave on upper half of area below eyes on median three-fourths, lateral and lower margins of concavity strongly, acutely carinate except carina interrupted at median line, vestiture inconspicuous except on epistoma; anterior margin of pronotum rather coarsely serrate; declivity more strongly impressed.

Distribution-- Guatemala.
Gutatemala: Volcán Zunil, Quezeltenango, 2T-V. 64, 1000 m. No. 626, shrul), S. L. Wood.

Biology. - Specimens were taken from radiate tumels in the same Compositae shrub as refertus.

Notes. - The above treatment was based on the type series of seven specimens.

## 47. Araptus concentralis (Schedl)

Neodryococtes concentralis Schedl, 1951. Dusenia 2:107 (Holotype, male: Mexico; Schedl Coll.)

Diagnosis.- This species is distinguished from macer (Bright) by the larger size, by the smaller antennal club, with sutures less strongly arcuate, and by the less abundant, shorter vestiture on the female frons.

Female.- Length $1.3-1.7 \mathrm{~mm}, 2.7$ times as long as wide; color very dark brown.

Frons rather broadly flattened from epistoma to well above eyes, ascending toward epistomal margin, very weakly convex above eves; surface shining, closely, deeply, rather finely punctured, much closer on upper half; vestiture of moderately abundant, very fine, moderately short hair in central area, longer at margins. Antennal club small, circular, sutures rather weakly arcuate, 1 septate, 2 and 3 marked by weak aseptate grooves.

Pronotum 1.15 times as long as wide; sides almost straight and parallel on basal half, rather broadly rounded in front; anterior margin a finely serrate costa; summit at middle; anterior slope (excluding anterior margin) armed by four concentric rows of basally fused asperities, a partial fifth row at summit; posterior areas smooth, shining, with numerous impressed points, rather fine, deep, moderately coarse. Posterior half glabrous.

Elytra I. 6 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal two-thirds, broadly rounded behind; striae not impressed except 1 weakly, punctures small, deep, close; interstriae twice as wide as striae, almost smooth, a few impressed lines and obscure points, impunctate. Declivity steep, weakly bisulcate; striae as on disc, 1 narrowly impressed; interstriae 1 weakly elevated, 2 weakly impressed, gradually ascending to rounded $3 ; 1$ and 3 each with a row of fine, rounded granules. Vestiture confined to declivity and sides, of sparse, fine, short, strial hair.

Male.-Similar to female except frons moderately, transversely impressed on lower half, punctures coarse, deep, not as close, vestiture sparse, short, inconspicuous.

Distribution- Jalisco to Oaxaca.
MEXICO: Jalisco: $16 \mathrm{~km} W$ Tizapán, 1s-V1I-53. shrub. Oaxaca: 6 km N Totolapan, 20-V1-67, 1100 m , No. 69, small tree. Puebla: 16 km S Matamoros, 14 -Vi67. 1600 m , No. 37, shrub. All were taken by me.

Biology.- Specimens were taken from radiate tunnels in twigs and branches of a small shrubby tree, possibly a Compositae.

Notes.- The above treatment was based on the holotype and on 58 other specimens.

## 48. Araptus macer (Bright)

Neodryococtes macer Bright, 1972, Canadian Ent. 104:1666 (Holotype, female; 8 km or 5 miles S San Andrés Tuxtla, Veracruz, Mexico; Canadian Nat. Coll., 12623)
Neodryocoetes tuberculatus Bright, 1972, Canadian Ent. 104:1665 (Holotype, female; Lake Catemaco, Veracruz, Mexico; Canadian Nat. Coll., 12622); Wood, 1973, Great Basin Nat. 33:173. Synonymy
Diagnosis. - This species is distinguished from concentralis (Schedl) by the smaller size, by the larger antennal club, with suture 1 strongly, angulately procurved, and by the longer, dense frontal vestiture of the female.

Female.- Length 1.2-1.4 mm, 2.5 times as long as wide; color light brown.

Frons flat from epistoma to vertex, partly impunctate (concealed by hair), marginal areas densely, very finely punctate except median line above; vestiture at margins dense, very long, incurved. Antennal club rather large, oval, suture 1 strongly procurved, others not indicated.
Pronotum as in concentralis except punctures on posterior areas much finer.

Elytra as in concentralis except punctures of discal striae not as close, in slightly irregular rows; granules on elytral declivity less numerous, larger, pointed; interstrial setae short, spatulate.

Male.- Similar to female except frons rather strongly convex except lower third rather strongly, transversely impressed, surface smooth, shining, punctures fine, close, vestiture sparse, inconspicuous.
Distribution.- Veracruz to Honduras.
MEXICO: Veracruz: Bright (1972:1665-1666) lists Ejipantla, Lago Catemaco, and San Andrés Tuxtla. HONDURAS: La Ceiba, Atlántida, $20-\mathrm{V}$ and 1-V1-49, at light, E. C. Becker.

Notes.- The above treatment was based on 2 paratypes of macer, 2 paratypes of $t u$ berculatus, and on 10 other specimens. The holotypes of both were also examined.

## 49. Araptus nigrellus Wood

Araptus nigrellus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):52 (Holotype, female; 10 km SE Cartago, Cartago, Costa Rica; Wood Coll.)
Diagnosis.- This and the following three species form a distinctive transitional group
between Araptus and species previously placed in Sphenoceros Schedl. They have a large antennal club, with finely marked, strongly procurved sutures, the costal apex of the elytra ascends slightly, the declivity is convex, and the elytral vestiture tends to be confined to the declivity, closely spaced, and more or less scalelike. This species is distinguished from others in the group by the more slender body, by the slender interstrial bristles, and by the subglabrous female frons.

Female.- Length $1.7-2.0 \mathrm{~mm}, 2.7$ times as long as wide; color black.

Frons convex, a weak, transverse impression above epistoma; surface strongly reti-culate-subgranulate above eyes, almost smooth and with a few small punctures below. Antennal club rather large, oval, sutures strongly arcuate, I septate.

Pronotum 1.1 times as long as wide; widest on basal third, sides moderately arcuate, converging toward narrowly rounded serrate anterior margin; summit at middle; asperities moderately coarse, confused; posterior areas shining, partly subreticulate, with low, longitudinal subasperate crenulations continuing almost to base, punctures obscure, associated with crenulations. Glabrous.

Elytra 1.7 times as long as wide, 1.7 times as long as pronotum; sides straight and parallel on slightly less than basal two-thirds, tapered then rather broadly rounded behind; striae not impressed except 1 weakly, punctures small, deep, spaced within row by diameter of a puncture; interstriae four times as wide as striae, almost smooth, with obscure, minute points, impunctate. Declivity moderately steep, convex; striae obscurely impressed, punctures smaller and less distinct than on disc; interstriae each with a row of very fine granules. Vestiture confined to declivity, of rows of narrowly spatulate interstrial bristles, each bristle as long as distance between rows, more closely spaced within a row.

Male.- Similar to female in all respects.
Distribution.- Costa Rica.
COSTA RICA: 10 km SE Cartago, Cartago, 3-VII-63, Nos. 13, 15, 24-1N-63, No. 205, 1800 m , Myrica pubescens, S. L. Wood.

Biology.- This locally common species was taken from radiate tunnels in the cambium region of limbs and boles of recently cut trees.

Notes. - The above treatment was based on the type series of 69 specimens.

## 50. Araptus vinnulus Wood

Araptus cinnulus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):53 (Holotype, female: San Ignacio de Acosta, San José, Costa Rica. Wood Coll.)
Diagnosis.- This species is distinguished from nigrellus Wood by the smaller size, by the stouter form, by the more widely spaced, stouter interstrial bristles, by the almost obsolete strial punctures, and by the frons.

Female.- Length $1.2-1.5 \mathrm{~mm}, 2.4$ times as long as wide; color very dark brown, almost black.

Frons broadly convex, lower third with broad, smooth, shining, median line: surface densely, coarsely, deeply punctured; upper two-thirds on median two-thirds with moderately abundant, fine, long hair. Antenna essentially as in nigrellus.

Pronotum 1.03 times as long as wide; as in nigrellus except less strongly tapered anteriorly, moderately rounded in front, posterior areas dull. Glabrous.

Elytra 1.44 times as long as wide, 1.44 times as long as pronotum; sides straight and parallel on basal half, tapered then rather narrowly rounded behind; striae not impressed, punctures minute, shallow, many almost obsolete; interstriae shining, with many very minute impressed points and shallow, irregular lines, impunctate. Declivity rather steep, convex; as on disc except interstriae each with a row of small, rounded granules. Vestiture confined to declivity, of rather stout, spatulate bristles, each slightly shorter than distance between rows, similarly spaced within a row.

Male.- Similar to female except frons rather strongly convex, surface strongly reticulate, subglabrous.

Distribution.- Costa Rica.
COSTA RICA: San lgnacio de Acosta, San José, 5-VII6i3. 1500 m , No. 31, Roupala complicata, S. L. Wood.

Biology. - Specimens were taken from radiate tumnels in the cambium region of branches 2 cm in diameter.

Notes.- The above treatment was based on the type series of 20 specimens.

## 5l. Araptus furvus Wood

Araptus furvus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):53 (Holotype, female; Cerro Punta, Chiriquí, Panama; Wood Coll.)
Diagnosis.- This species is distinguished from vinnulus Wood by the larger size, by the more closely spaced interstrial setae, by the presence of strial hair, and by the longer, more abundant setae on the female frons.

Female.- Length $1.7-2.2 \mathrm{~mm}, 2.4$ times as long as wide; color almost black.

Frons convex, strongly reticulate, punctures rather small, sparse; upper two-thirds with rather dense marginal fringe of long hair, longest setae on vertex extend about two-thirds distance to epistomal margin; distance from upper level of eyes to vertex equal to 1.2 times distance from epistoma to upper level of eyes. Antenna as in cinnulus.

Pronotum 1.03 times as long as wide; as in cinnulus except more distinctly constricted on anterior half.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; as in vinnulus exeept strial punctures on basal half of dise more distinct; declivital strial punctures obsolete. Vestiture confined to declivity, of rows of minute, fine, strial hair, and rows of longer, spatulate, interstrial bristles, each bristle slightly shorter than distance between rows, more closely spaced within a row, each bristle very slender on its basal half, flattened on its apical half.

Male. - Similar to female except frons broadly convex, glabrous.

Distribution.- Panama.
PANAMA: Cerro Punta (Volcán Chiriquí), Chiriquí, 11-1-64, 1800 m . No. 422, Roupala limbs, S. L. Wood.

Biology.- Specimens were taken from longitudinal galleries in the phloem of broken tree limbs. One or rarely two females were associated with each male. Larval mines were entirely within the phloem and did not show on the surface of peeled bark.

Notes. - The above treatment was based on the type series of 47 specimens.

## 52. Araptus furvescens Wood

Araptus furvescens Wood, 1974. Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):53 (Holotype, female; Volcán Pacaya, Esquintla, Guatemala; Wood Coll.)

Diagnosis.- This species is distinguished from furcus Wood by the smaller average size, by the feebly impressed declivital striae, with minute strial punctures indicated, and by the longer female frontal pubescence. with pubescent area extending higher on the vertex.

Female.- Length $1.5-1.9 \mathrm{~mm}$; as in furvus Wood except female frontal pubescent area extending higher on vertex, distance from upper level of eyes to upper limits of pubescent area 1.5 times distance from epistoma to upper level of eyes, longest setae on vertex almost reaching epistomal margin, pubescent area extending ventrad in lateral areas almost to epistoma; declivital striae weakly impressed, punctures very small but usually visible; declivital interstrial bristles more nearly scalelike, each flattened on twothirds or more of its length.

Male. - Similar to female except frons more broadly convex, glabrous.

Distribution.-Guatemala.
GUATEMALA: Volcán Pacaya, Esquintla, 1-VI-64. 1300 m , No. 652, Roupala, S. L. W'ood.

Biology.-As in furvus.
Notes.- The above treatment was based on the type series of 42 specimens.

## 53. Araptus lepidus Wood

Araptus Icpidus Wood, 1974, Brighan Young Univ. Sci. Bull. Biol. Ser. 19(1):54 (Holotype, female: Volcán Puntarenas, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from the above three species in this group by the presence of discal interstrial punctures and by the stouter body form. It is distinguished from aztecus Wood by the narrowly rounded, serrate anterior margin of the female pronotum and by the very different female frons.

Female.- Length $1.7-2.0 \mathrm{~mm}, 2.26$ times as long as wide; color dark brown.

Frons convex, median area strongly impressed from slightly above upper level of eyes to just above epistoma, lower lateral margins of impressed area moderately elevated; surface shining, smooth, punctures rather fine, deep, sparse; glabrous except near epistoma. Antennal club very large, about as in nigrellus Wood, only median half of suture 1 septate.

Pronotum 1.05 times as long as wide; essentially as in vinnulus Wood, except crenulations on ridges on posterior half almost obsolete, posterior areas smooth, shining, punctures very small, shallow, rather sparse. Glabrous.

Elytra 1.3 times as long as wide, 1.2 times as long as pronotum; sides almost straight and parallel on basal half, rather broadly rounded behind; striae not impressed, punctures small, shallow, rows irregular on anterior twothirds; interstriae smooth, shining, about four times as wide as striae, punctures uniseriate, similar to those of straie. Declivity steep, convex; sculpture essentially as on disc except punctures slightly smaller, deeper. Vestiture largely confined to posterior half, consisting of interstrial rows of slender scalelike bristles, each slightly shorter than distance between rows, similarly spaced within a row.

Distribution.- Costa Rica.
COSTA RICA: Volcan, Puntarenas, 11-Xll-63, 1000 m, No. 304, tree branch, S. L. Wood.

Biology.- Specimens were taken from the phloem of a broken branch.

Notes.- The above treatment was based on the type series of four female specimens.

## 54. Araptus aztecus (Wood)

Sphenoceros astecus Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):54 (Holotype, female; 6 km W Tepic, Nayarit, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from lepidus Wood by the larger average size, by the acutely angulate anterior margin of the female pronotum, by the very different female frons, and by the confused punctures on the elytral disc.

Female.- Length $1.8-2.2 \mathrm{~mm}$, about 2.1 times as long as wide; color very dark reddish brown.

Frons broadly flattened from vertex to slightly below upper level of eyes, a thick, low, transverse elevation between flattened area and emarginate epistoma, its ends elevated to form a pair of rather strong tubercles; flattened area almost smooth, subshining, very minutely, densely punctured; margin of upper half of flattened area ornamented by a row of very long hair (except on median line), longest setae reaching epistoma. Antenna as in lepidus.

Pronotum 1.1 times as long as wide; triangular, anterior angle acutely acuminate: widest near base, basal half of sides rather weakly arcuate; asperities rather coarse, confused; posterior areas as in lepidus. Glabrous.

Elytra as in lepidus except discal punctures slightly more confused, declivital striae 1 im pressed, punctures in rows. Vestiture as in lepidus.

Male. - Similar to female except frons convex, rather coarsely punctured, median line slightly raised; pronotum as in female lepidus.

Distribution.-Nayarit and San Luis Potosí.
MEXICO: Nayarit: San Blas. 12-vil- 65.70 m , No. 235. sapling, S. L. Wood: 6 km W Tepic, 13-VII-65. 1040 m. No. 240 . himbs. S. L. Wood. San Luis Potosí: El Salto. 19-V1-53. Ficus (accidental?), S. L. Wood.

Brology.- This monogamous species constructs transverse, biramous tunnels in the cambium region of cut or unthrifty host material. Larval mines are longitudinal and entirely in the phloem. One dead female specimen was taken from an abandoned Corthylus gallery, in Ficus, where it had apparently found temporary refuge.

Notes.- The above treatment was based on the type series of 11 specimens and on 18 other specimens.

## Genus CONOPHTHOCRANULU'S Schedl

Conophthocranulus Schedl, 1935. Rev. de Ent. 5:343 (Type-species: Conophthocranulus blackmani Schedl, monobasic)
The status of this genus is uncertain. Of the seven species subsequently assigned to it by Schedl, none are related in even a remote sense to the type-species. An examination of the type suggested that blackmani Schedl is nothing more than a very large Pityophthorus allied to crotonis Wood.

## Conophthocranulus blackmani Schedl

Conophthocranulus blackmani Schedl. 1935, Rev. de Ent. 5:344 (Holotype, female; Turrialba, Cartago, Costa Rica; Schedl Coll.)
Diagnosis.- The large size and the shape of the pronotum distinguish this species from all other Pityophthorus-like species.

Female.- Length $3.3 \mathrm{~mm}, 2.2$ times as long as wide; color dark reddish brown.

Frons concealed on holotype, lower area flattened and with rather short, moderately abundant pubescence at least to level of antennal insertion. Antennae missing except for left scape.

Pronotum 0.98 times as long as wide; widest one-fourth of length from base; sides rather strongly arcuate on basal two-fifths, strongly converging on anterior three-fifths to rather narrowly rounded anterior margin; anterior margin costate, weakly serrate; summit broad, one-third pronotum length from base; anterior slope closely, rather finely asperate to summit, low asperities continued to base laterally almost to summit; posterior surfaces somewhat reticulate, with a few impressed points; pronotum rather similar to Conophthorus. Short, stout setae in asperate area sparse, inconspicuous.

Elytra 1.3 times as long as wide, 1.35 times as long as pronotum; sides feebly arcuate and subparallel on basal three-fourths, rather abruptly rounded behind, then rather shallowly emarginate on median fourth; disc occupying slightly more than basal half; discal punctures moderately fine, rather deep, surface shining, irregular, weakly subcrenulate; moderately abundant impressed points present. Declivity broadly sulcate much as in Ips, but lateral margins abruptly rounded, unarmed: posterolateral margins strongly, acutely elevated from striae 2 to about interstriae 7 ; face of impressed area with strial punctures indicated, interstriae 2 distinctly impressed; interstrial punctures less clearly impressed, minute granules on 3. Glabrous.

Tibiae typical of Pityophthorus.
Distribution.- Costa Rica.
COSTA RICA: Turrialba, 800 m , SLG. Schild.
Notes.- The above treatment was based on the holotype. It appears to be allied to Pityophthorus crotonis Wood from Venezuela.

## Genus SpERMOPHTHORUS

da Costa Lima
Fig. 198
Spermophthorus da Costa Lima, 1929. Suppl. Mem. Inst. Oswaldo Cruz 8:111 (Type-species: Spermophthorus apuleiae da Costa Lima, monobasic)
Diagnosis.- This genus closely resembles certain seed infesting Araptus except that the small antennal club has sutures 1 and 2 partly septate as in many neotropical Pityophthorus.

The tibiae are broader and bear more denticles than in Pityophthorus, the pronotum also lacks a definite summit, and the transition from the asperate to the punctured areas is gradual.

Description.- Length $1.4-1.8 \mathrm{~mm}, 2.4$ times as long as wide; color reddish brown to dark brown.

Frons dimorphic, male variously excavated, female convex, vestiture inconspicuous. Antennal scape elongate; funicle 5 -segmented; club small, largely glabrous, sutures 1 and 2 almost straight, both partly septate at sides. Pronotum without a definite summit, finely asperate anteriorly, transition from asperate to punctured areas gradual. Elytra striate, conservatively sculptured. Tibiae moderately stout, lateral margin armed by denticles on more than apical half.

Fig. 199. Pityophthorns, Pityoborus, Cnatholeptus spp., antennae and protibiae: 29-30. Pityophthorus deleoni, male, 31, same, female; 32, 32a, Pityoborus secumdus; 33, Pityophthorus regularis; 34, Pityophthorus costalimai; 35. Gnatholeptus suberibratus; 36, Gnathoteptus shaunoni. (After Blackman 1942:pl. 22.)

Distribution.- Costa Rica and S South America; three species are known, one from Costa Rica.

Biology.- Two species breed in seeds, one evidently in a gall.

## Spermophthorus aberrans Wood

Spermophthorus aberrans Wood, 1968, Great Basin Nat. 28:11 (Holotype, male; 6 km S San Vito, Puntarenas, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from both South American species by the reduced size of the head, by the general contour and sculpture of the pronotum and elytra, and by the very different frons in both sexes.

Male.- Length 1.4-1.7 mm, 2.4 times as long as wide; color dark brown.

Frons above upper level of eyes convex, with a low median elevation; rather abruptly, strongly, broadly impressed at upper level of eyes, subconcave area extending from eye to eye to epistomal margin; center of impressed area bearing a pointed tubercle; central part of each ventrolateral fourth of impressed area armed by a large, rounded, strongly developed process about twice as high as its basal width, directed cephalad and very slightly mesad; entire surface dull, above upper level of eyes also clearly reticulate and finely punctured; vestiture inconspicuous.

Pronotum 1.1 times as long as wide; sides almost straight and parallel on basal half, then rather abruptly rounded and continued straight to very narrow, narrowly rounded anterior margin; anterior margin a continuous, unbroken elevated costa, one pair of low teeth at its ends; dorsal profile a continuous, gradual arch from anterior to posterior margins; isolated, small, crenulate asperities extend to basal margin, surface between asperities irregular, apparently with obscure, coarse reticulation. Vestiture consisting of moderately abundant, erect, slender scales.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal half, then converging gradually to narrowly rounded posterior margin; striae 1 feebly, others not impressed, punctures small, shallow, not close or clearly evident; interstriae perhaps three times as wide as striae, very irregular, minutely rather densely punctured, with median row of small,
subvulcanate, squamiferous punctures. Declivity convex, rather steep; striae weakly impressed, punctures more distinct; interstriae 2 strongly narrowed, abruptly, strongly impressed, obsolete before apex; interstrial tubercles slightly larger. Vestiture consisting of interstrial rows of rather slender, erect scales.
Female.- Similar to male except frons weakly, uniformly convex to epistoma, median elevation continued to epistomal margin, with central tubercle minute, lateral tubercles minute but evident.

Distribution.- Costa Rica.
COSTA RICA: 6 km S San Vito. Puntarenas, 19-21-1II-67. C. Valencio.
Biology.- Specimens were taken from a pear-shaped gall ( 3.5 by 4.5 cm ) that was picked up on the forest floor.

Notes.- The above treatment was based on the type series of 32 specimens.

## Genus PSEUDOPITYOPhTHORUS Swaine

Pseudopityophthorus Swaine, 1918, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(2):93 (Type-species: Crypturgus minutissimus Zimmermann, original designation)
Diagnosis.- This genus is distinguished from Pityophthorus Eichhoff by the strongly reduced or absent striae, by the more abundant elytral vestiture, by the tuberculate posterior face of the protibiae, by the pubescent frons forming a male character, and by the distinctive biological characters.

Description.- Length $1.2-2.6 \mathrm{~mm}$, 2.6-3.1 times as long as wide; color medium, brown to almost black; vestiture hairlike to scalelike; rather abundant.
Frons usually dimorphic, convex to shallowly concave in either sex, abundant frontal vestiture a male character, in a few species females similarly pubescent, most females subglabrous. Antennal scape elongate; funicle 5 -segmented; club moderately large, sutures 1 and 2 partly septate, rather weakly to strongly arcuate. Elytral striae weak to obsolete, surface punctures on disc usually small, confused, abundant; declivity simple, steep, usually convex, very conservatively sculptured. Anterior tibiae tuberculate on posterior face.

Distribution.- Oregon and Quebec to Colombia; 22 species are known; 21 occur in

North and Central America, and one is from Colombia.

Blology. - All species except fagi occur in Quercus, although several are capable of breeding in other hosts. Cut, broken, or unthrifty branches, limbs, or boles are selected for attack. In all species an entrance tunnel and a short longitudinal tunnel are formed in the cambium region by the male; he may also begin two transverse egg tunnels near the middle of the longitudinal gallery. He is normally joined by two females that extend the straight, transverse egg galleries. The larval mines are longitudinal and are entirely in the phloem, although they usually show on the inner surface of peeled bark. In an area where several species occur on the same host tree, each beetle species usually confines its attacks to a particular part of the host, such as small branches, large limbs, or bole. Where only one species occurs on a host, it usually infests all areas of the tree.

Fig. 200. Pityophthorus spp., antennae and protibiae: 37, leiophyllae; 38, sambuci; 39-40, alni; 41-42, subopacus; 43-44, ciliatus: 45, nocturnus; 46, rudis. (After Blackman 1942:pl. 23.)

## Key to the Species of Pseudopityophthorus

2(1). Elytral declivity with either definite rows of strial punctures or with rows of conspicuous granules on interstriae 1-3

- Elytral declivity entirely devoid of granules (feeble granules on 1 and 3 in hondurensis), punctures either obsolete or strongly confused
3(2). Elytral declivity moderately to strongly flattened (except hispidus), interstriae 1 moderately elevated, punctures on striae 1 and 2 distinctly impressed, frontal hair a male character
- Elytral declivity convex to feebly impressed, punctures obsolete, interstriae 1-3 armed by rows of small granules; both sexes similarly ornamented by frontal hair
4(3). Pronotal disc longitudinally rugose from summit to basal margin; elytral declivity narrowly convex, discal and declivital punctures very coarse for this genus; elytral vestiture unusually long for this genus, coarse; Valle de Mexico; 2.0 mm
- Pronotal disc smooth, finely punctured; elytral declivity rather strongly impressed; elytral vestiture hairlike
5(4). Elytral declivity more gradual, with punctures on striae 1 and 2 and with rows of granules on interstriae 1 and 3,2 weakly impressed and unarmed; Colombia; $1.3-1.5 \mathrm{~mm}$ colombianus Wood
- Elytral declivity subvertical, striae 1 and 2 punctured, interstriae unarmed; Nayarit to Chiapas; 1.8 mm

2. declivis Wood

6(3). Interstrial bristles slender, shorter, spaced by one to two times length of a bristle; pronotal punctures averaging twice as large as those on elytral disc; frontal vestiture slightly less abundant in both sexes; Arizona; $1.3-1.7 \mathrm{~mm}$ 3. granulatus Blackman

- Interstrial bristles stout, longer, spaced within a row by distances less than length of a bristle; pronotal punctures fine, not larger than those on elytral disc; frontal vestiture slightly more abundant in both sexes
$7(6)$. Stout, longer interstrial and fine, short, hairlike strial setae on declivity in definite rows; declivital granules larger, equally developed on interstriae $1-3$; Chiapas to Honduras (see also 5. denticulus Wood); 1.6-2.0 mm
- $\quad$ Strial and interstrial setae on declivity stout, almost scalelike, largely confused; declivital granules smaller, of reduced size or entirely obsolete on interstriae 2; Hidalgo to Veracruz; $1.3-1.6 \mathrm{~mm}$

8(2). Pronotum at least 1.25 times as long as wide; antennal club at least 1.5 times as long as scape; elytral disc subglabrous on basal half, posteriorly strial setae less than one-fourth as long as fine interstrial bristles

- Pronotum less than 1.2 times as long as wide; antennal club less than 1.2 times as long as scape; elytral disc pubescent, strial setae at least two-thirds as long as coarser interstrial bristles
$9(8)$. Male and female frons subglabrous, female frons with no indication of a median carina; Maine and New York to E Texas and Florida; 1.2-1.4 mm 7. asperulus (LeConte)
- Male frons bearing a rather sparse tuft of long vellow hair, female frons glabrous or pubescent

10(9). Female frons pubescent as in male; declivital interstriae 1 and 3 each with two or three minute granules, 2 feebly impressed: Chiapas to Honduras; 1.2-1.6 mm (see also 9. cincinnatus Blandford)
8. hondurensis Wood

- Female frons glabrous; declivity convex, with no indication of granules

11(9). Female frons transversely impressed, coarsely, rather closely punctured; interstrial bristles longer than distance between rows; Veracruz to Chiapas; 1.3-1.6 men
10. singularis Wood

- Female frons flattened, a short median carina just below upper level of eves; interstrial bristles half as long as distance between rows: Hidalgo and Veracruz to Chiapas; 1.2-1.4 mm

11. tenuis Wood

12(8). Interstrial setae two to four times as long as distance between rows; all discal setae hairlike, ground vestiture on declivity scalelike; male frons shallowly concave; Virginia and North Carolina; $1.8-2.0 \mathrm{~mm}$............. 12. pubescens Blackman

- Interstrial setae shorter than distance between rows; all elytral setae hairlike; male frons flat

13(12). Punctures on pronotal disc moderately fine; elytral declivity narrowly, strongly
convex; Pennsvlvania to West Virginia. Fagus: convex; Pennsylvania to West Virginia; Fagus; 1.4-1.5 mm

- Punctures on pronotal disc very fine; elytral declivity more broadly convex, less strongly arched; California to Arizona; $1.5-1.9 \mathrm{~mm}$

14(1). Elytral vestiture fine, short, hairlike; elytral declivity convex, smooth, shining, devoid of punctures and vestiture (recently emerged specimens sometimes with declivital scales): Durango and Hidalgo to Oaxaca; $2.0-2.5 \mathrm{~mm}$....................... punctures evident
15(14). Smaller; pronotal disc finely reticulate; elytral punctures minute; elytral vestiture rather fine, short, of uniform proportions on disc and declivity; frons strongly reticulate, planoconcave to upper level of eyes; Maine and Minnesota to Louisiana and Florida; $1.5-1.8 \mathrm{~mm}$
Larger; pronotal disc never reticulate, smooth (except coarsely reticulate in squamosus); elytral punctures moderately fine to rather coarse; elytral vestiture rather coarse, ground vestiture more nearly scalelike on declivity (except
comosus) .............................................................................................................

16(15). Pronotum strongly reticulate; elytral vestiture on disc of minute, fine hair, usually abraded, on declivity of abundant small scales, if scales abraded surface densely, finely punctured; antennal club small for this genus, sutures almost straight; Durango to Sinaloa; 2.1-2.4 mm
18. squamosus Bright

- Pronotum smooth, shining; antennal club larger, sutures moderately to strongly arcuate
17(16). Elytral ground vestiture hairlike on disc and declivity; posterior half of elytra with rows of erect slender bristles, each bristle only slightly longer than ground vestiture; male frons glabrous on central half, with a rather dense row of long, dark hair on margins; female frons with rather abundant, moderately short hair except glabrous on median fourth, longest on lower half; Oaxaca; $2.2-2.4 \mathrm{~mm}$.

17. comosus Bright

18(17). Declivital ground vestiture subplumose, stout, scalelike; elongate setae, if present, stout, blunt, rarely more than twice as long as ground cover

- Declivital ground vestiture rather strongly plumose, elongate setae slender, almost hairlike, pointed, some at least four times as long as ground cover
19(18). Discal vestiture uniformly short, declivital vestiture either similar or setae in position of interstriae 1 and 3 sometimes erect, slightly longer; New York and Michigan to Florida and Honduras; $1.5-2.4 \mathrm{~mm}$

19. pruinosus (Eichhoff)

- $\quad$ Setae on some discal and declivital interstriae conspicuously longer and stouter than setae in ground cover
20(19). Erect scales on all interstriae of disc and all except 2 on declivity, each scale about six to eight times as long as wide; male frons broadly flattened, with no indication of a callus; Sinaloa; $1.6-1.8 \mathrm{~mm}$ 20. festivus Wood
- Erect scales on alternate odd-numbered interstriae of disc and declivity, each scale more than ten times as long as wide, some pointed on sides and near base of disc; male frons transversely impressed, a distinct median callus well above upper level of eyes; Arizona to Chiapas; $1.8-2.2 \mathrm{~mm}$

21. opacicollis Blackman
$21(18)$. Elongate elytral setae stout, less abundant, absent on declivital interstriae 2; pronotal disc usually with minute, sparse hair over entire surface (often abraded); Washington to California; $1.7-2.5 \mathrm{~mm}$
22. pubipennis (LeConte)

Elongate elytral setae hairlike, more abundant, on all declivital interstriae; pronotal disc glabrous except at margins; Arizona to Chihuahua; $1.7-2.6 \mathrm{~mm} .$.
23. yavapaii Blackman

## 1. Pseudopityophthorus hispidus Eggers

Pseudopityophthorus hispidus Eggers, 1931, Ent. Blătt. 26:170 (Holotype, female; Valle de Mexico, Mexico ; Berlin Mus.)
Diagnosis.- This unique species is distinguished from all others in the genus by the more rugose pronotal disc, by the coarser elytral punctures, and by the stout, very long elytral vestiture.

Female.- Length $2.0 \mathrm{~mm}, 2.7$ times as long as wide; color brown, pubescence pale.

Frons broadly convex, surface shining, feebly subaciculate; vestiture fine, short,
sparse. Antennal club apparently typical of genus.

Pronotum 1.1 times as long as wide; widest near middle, sides weakly arcuate on slightly more than basal half, rather narrowly rounded in front; anterior margin armed by 16 coarse serrations, median ones distinctly larger; summit at middle; anterior slope armed by closely set, small asperities; posterior area subgranulate, with fine, irregular, longitudinal rugosities from summit to basal margin. Vestiture moderately abundant, of delicate, coarse, moderately long hair.

Elytra 1.7 times as long as wide, 1.5 times as long as pronotum; sides straight and parallel on basal two-thirds, rather narrowly rounded behind; discal surface shining, with moderately abundant impressed points, punctures confused, moderately coarse (very coarse for this genus). Declivity rather steep, narrowly convex; declivital punctures in strial rows, interstriae twice as wide as striae, with very sparse interstrial punctures. Vestiture of rather abundant, long, stout but delicate setae, and slightly longer, coarser rows of interstrial setae on posterior half of elytra on interstriae $1,3,5$, and 7 , these setae about two-thirds as long as distance between alternate rows.

Distribution. - Presumably Mexico or the Distrito Federal.
Only the type specimen is known; it is labeled "R.d.M. Mexico" but was published by Eggers as "Valle de Mexico, Mex."

Notes.- The above treatment was based on the holotype.

## 2. Pseudopityophthorus declivis Wood

Pseudopityophthorus dechivis Wood, 1971, Brigham Yourg Univ. Sci. Bull., Biol. Ser. 15(3):50 (Holotype, female; Laguna Santa María, Nayarit, Mexico, Wood Coll.)
Pscudopityophthorus truncatus Bright. 1972. Canadian Ent. 104:1673 (Holotype, male; 184 km S Oaxaca, Oaxaca, Mexico: Canadian Nat. Coll.): Wood, 1973, Great Basin Nat. 33:184. Synonymy
Pseudopityophthorus curtus Bright, 1972. Canadian Ent. 104:1674 (Holotype, female: 13 km or 8 miles N Ocosingo, Chiapas, Mexico, 2-VI-69. Quercus, D. E. Bright; Canadian Nat. Coll.. 12634); Wood, 1973, Great Basin Nat. 33:184. Synonymy
Diagnosis.- This species is distinguished by the rather strongly impressed subvertical declivity, on which the rather coarse punctures of striae 1 and 2 are clearly impressed, and by the hairlike vestiture.
Female.- Length $1.8 \mathrm{~mm}, 2.6$ times as long as wide; color very dark brown.

Frons broadly convex above eyes, almost flat below, with epistomal area weakly elevated; surface very coarsely, deeply punctured above and at sides, almost impunctate in median area below; vestiture rather sparse except on epistoma, of fine, long hair. Antennal club moderately large, widest through segment 3 .
Pronotum 1.1 times as long as wide; widest near base, sides feebly arcuate and
converging very slightly on basal twothirds, rather broadly rounded in front; anterior margin armed by a continuous, elevated, serrate costa, summit at middle; anterior area rather finely asperate; posterior area rather coarsely, deeply, closely punctured, general surface subreticulate. Subglabrous.
Elytra 1.6 times as long as wide, 1.4 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly bisinuate behind; striae not impressed, punctures rather fine (coarse for this genus), deep; interstriae three times as wide as striae, with very fine, irregular lines, numerous impressed points, impunctate. Declivity subvertical, flattened, confined to less than posterior fifth; striae 1-3 clearly indicated, punctures shallow; surface almost flat except for strongly elevated interstriae 1 ; very fine punctures on all interstriae except 2 . Vestiture confined to posterior third, of very minute strial hair, and rows of erect, moderately long, interstrial bristles of uniform length.
Distribution.- Nayarit.
MEXICO: Chiapas: 13 km or 8 miles N Ocosingo. $2-$ V1-69. Quercus, D. E. Bright. Jalisco: 60 km E Guadalajara, 22-IV-7T., Quercus, M. M1. Furniss. Nayarit: Laguna Santa Maria. 6-VII-65, 1000 m , No. 203 Quercus. S. L. Wood. Oxaca: 184 km S Oaxaca, 12-VI-71, $2000 \mathrm{~m}, \mathrm{D}$. E. Bright.

## Host.- Quercus sp.

Biology.- One specimen was taken from an oak limb 30 cm in diameter.

Notes. - The above treatment was based on the holotypes of declivis and curtus, on two paratypes of truncatus, and on eight other specimens. The declivital punctures of curtus are slightly larger than in declivis; there are also minor differences on the pronotum, but the head and prothorax of the type of curtus are detached from the remainder of the body, and their slightly larger size suggests they may not belong to the remainder of the body. The paratypes of itruncatus have the declivital punctures slightly smaller than in declivis and the declivital setae are slightly longer and more slender. With only 12 specimens available, from four different localities, it is not possible to determine whether these differences are due to normal intrapopulational variation, geographical variation, or to specific differences. In view of the exceedingly close similarity of the
unique declivity, I consider all to represent the same species.

## 3. Pseudopityophthorns granulatus Blackman

 Fig. 202Pseudopityophthorus granulutus Blackman, 1931, J. Washington Acad. Sci. 21:230 (Holotype, male: Prescott N.F., Arizona; U.S. Nat. Mus., 43425)
Diagnosis.- This species is distinguished from granulifer Wood by the smaller size, by the shorter, more widely spaced interstrial bristles, by the larger pronotal punctures, and by the smaller average size of declivital granules.

Male.- Length 1.3-1.7 mm, 3.0 times as long as wide; color very dark reddish brown.

Frons as in gramulifer except setae very slightly shorter and evidently less abundant.

Pronotum 1.2 times as long as wide; as in granulifer except punctures on dise slightly larger, deeper, impressed points less conspicuous and less numerous.

Elytra 1.7 times as long as wide, 1.4 times as long as pronotum; as in granulifer except declivital granules usually smaller, less numerous; vestiture finer, shorter, more widely spaced, length of interstrial bristles shorter than distance between rows, spaced within a row by one to two lengths of a bristle.

Female.- Similar to male.
Distribution- Arizona.
USA: Arizona: Prescott N.F., 10-V1-30, Quercus, M. W. Blackman: Arivaca Road, 23-VIII-58, Qucrcus, S. L. Wood; Madera Canyon, 24-Vill-58, Qucrcus. S. L. Wood; Mt. Bigelow, Santa Catalina Mits., 11-VI-69. Quercus hypoleucoides, S. L. Wood; Santa Rita Mits., 13VI, Hubbard and Schwarz.

Hosts.- Quercus hypoleucoides, Q. spp.
Biology.- Specimens were taken from cut and broken branches less than 5 cm in diameter. The habits are as described for the genus.

Notes.- The above treatment was based on the holotype, on 53 paratypes, and on 21 other specimens.

## 4. Pseudopityophthorus granulifer Wood

Pseudopityophthorus granulifer Wood, 1967, Great Basin Nat. 27:42 (Holotype, female; Zamorano, Morazan, Honduras; Wood Coll.)
Diagnosis.- This species is distinguished from granulatus Blackman by the larger size, by the stouter, longer, closer interstrial
bristles, by the smaller discal punctures on the pronotum, and by the slightly different elytral declivity.

Male.- Length $1.6-2.0 \mathrm{~mm}, 2.8$ times as long as wide; color almost black.

Frons plano-convex over a broad area, with a dense marginal fringe of long, yellow hair as in male of most species. Segments 2 and 3 of antennal club equal in width.

Pronotum 1.2 times as long as wide; sides gradually, arcuately narrowed toward rather broadly rounded anterior margin; anterior margin armed by about 14 serrations; summit indefinite, at middle; posterior area smooth and shining, with fine, rather sparse, deep punctures and more abundant minute points; vestiture limited to sides and asperate area.

Elytra 1.5 times as long as wide; sides almost straight and subparallel on basal twothirds, rather narrowly rounded behind; striae I weakly impressed, others not at all impressed, punctures very small, shallow, in rather indefinite rows; interstriae obscure, with a few punctures, points, and surface lines. Decliviy convex, rather steep, with interstriae 2 impressed; strial punctures obsolete; interstriae 1,2 , and 3 each armed by a row of rounded granules that decrease in size and number toward apex; declivital surface smooth, dull. Vestiture consisting of rather sparse, erect bristles arranged in fine strial and coarse interstrial rows; some interstrial bristles on declivity strongly flattened.

Female.- Similar to male in all respects.
Distribution.- Chiapas to Honduras.
MEXICO: Chiapas: 8 km SE San Cristóbal de las Casas, 5-VII-56, D. D. Linsdale; Yerba Buena, 32 km N Bochil, 10-VI-69, Quercus, D. E. Bright. GUATEMALA: Guatemala City, 30-V-64, flight, S. L. Wood. HONDURAS: Zamorano, Morazán, I8-IV-64, Quercus hondurensis and $Q$. sapotaefolia, S. L. Wood.

Hosts.- Quercus hondurensis, $Q$. sapotaefolia.

Biology.- Specimens were taken from broken branches $3-5 \mathrm{~cm}$ in diameter. Habits were as described for the genus.

Notes.- The above treatment was based on the type series of 18 specimens, and on 2 other specimens.

A male fron Hochixtlan, Oaxaca, is tentatively assigned to this species. The elytral disc near the declivity is more rugosely punctured and the interstrial bristles on the declivity are slightly stouter and longer.

## 5. Pseudopityophthorus denticulus Wood

Pscudopityophthorus denticulus Wood, 1977, Great Basin Nat. 37:216 (Holotype, female; Boot Springs, Big Bend National Park, Brewster Co., Texas: Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from granulifer Wood by the different frons, by the less definite discal striae, by the more widely spaced, more slender interstrial bristles, and by the near absence of granules and bristles on declivital interstriae 2.
Female.- Length 1.9 mm (paratypes $1.6-2.0 \mathrm{~mm}), 2.9$ times as long as wide; color dark brown.
Frons as in granulifer except more shallowly, more broadly concave, punctures smaller, more widely spaced.
Pronotum and elytra as in granulifer except strial punctures on disc in less definite rows, erect interstrial setae more slender, more widely spaced, spaced by distances equal to length of a seta, setae and granules absent from declivital interstriae 2 , one or two granules sometimes present near base or apex.
Male. - Similar to female in all respects except antennal club sometimes more slender.
Distribution.- Texas.
USA: Texas: Boot Springs, Big Bend N.P., Brewster Co., 20-VIl-74, Quercus, D. E. Bright.
Notes. - The above treatment was based on the type series of 19 specimens.

## 6. Pseudopityophthorus virilis Wood

Pseudopityophthorus virilis Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):50 (Holotype, male; 1 km W Las Vigas, Veracruz, Mexico; Wood Coll.)
Diagnosis.- This species has the frons ornamented by setae in both sexes; it remotely resembles granulifer Wood, but it is distinguished by the smaller size, by the distinctly punctured elytral declivity, and by the presence of granules only on interstriae 1 and 3 .
Male. - Length $1.3-1.6 \mathrm{~mm}, 2.7$ times as long as wide; color black.

Frons transversely impressed, flattened from above eyes to epistoma; surface somewhat coarsely punctured above and at sides; evidently impunctate below in median area; vertex ornamented by a rather dense brush, its longest setae exceeding epistomal margin,
a few additional setae at sides and on epistomal area. Antenna about as in granulifer.
Pronotum as in granulifer except teeth on anterior margin of pronotum larger, punctures on disc very slightly larger, impressed points much smalier.
Elytra 1.6 times as long as wide; outline as in granulifer; punctures on dise confused, not in rows except near declivity, small; surface subshining, with a few irregular lines and impressed points. Declivity steep, convex; interstriae 1 and 3 each bearing a row of fine, rounded granules, three indistinct rows of minute, setiferous punctures between rows of granules, lateral areas similarly punctured. Vestiture almost hairlike at base, becoming scalelike toward declivity, those setae apparently derived from interstriae distinctly longer than those derived from striae; longest scales on declivity rather short, about six times as long as wide.
Female.- Similar to male.
Distribution.- Hidalgo to Veracruz.
MEXICO: Hidalgo: Tlahuehmpa, Zacualtipan, 16-X80, Quercus, T. H. Atkinson. Veracruz: $1 \mathrm{~km} W$ Las Vigas, 5-V11-67, No. 159. Quercus. S. L. Wood.
Biology.- Specimens were taken from a broken branch 3 cm in diameter. The habits were as described for the genus.
Notes. - The above treatment was based on the type series of 21 specimens.

## 7. Pseudopityophthorus asperulus (LeConte)

 Fig. 202Cryphalus asperulus LeConte, 1868, Trans. Amer. Ent. Soc. 2:155 (Holotype, male; Virginia; Mus. Comp. Zool., 1008)
Pseudopityophthorus asperulus: Blackman, 1931, J. Washington Acad. Sci. 21:244
Pseudopityophthorus gracilis Blackman, 1921, Mississippi Agric. Expt. Sta. Tech. Bull. 10:6 (Lectotype, male; Natchez, Mississippi; U.S. Nat. Mus., present designation); Blackman, 1931, J. Washington Acad. Sci. 21:228. Synonymy
Diagnosis.- This species is distinguished from tenuis Wood by the flattened, unarmed, subglabrous frons in both sexes and by the finer pronotal and elytral punctures.
Male.- Length $1.2-1.4 \mathrm{~mm}, 3.1$ times as long as wide; color very dark brown.

Frons rather broadly flattened from epistoma to well above upper level of eyes; surface shining, obscurely, shallowly, coarsely punctured; vestiture very sparse, short, inconspicuous. Antennal club moderately large,
widest through segment 3 , segment 1 short, sutures I and 2 moderately procurved.

Pronotum 1.3 times as long as wide; essentially as in granulatus Blackman except punctures on discal area very fine, rather shallow. Posterior half glabrous.

Elytra 1.8 times as long as wide, 1.5 times as long as pronotum; sides straight and parallel on basal two-thirds, rather narrowly rounded behind; striae not impressed, punctures small at base, becoming minute to obsolete at base of declivity; interstriae subshining, with some points and many fine, irregular lines, punctures evidently obsolete. Declivity steep, convex; strial punctures obsolete on surface, interstriae smoother than on disc, very minute impressed points usually indicated. Vestiture rather short, of rows of minute, fine strial hair, and rows of distinctly longer, fine, erect, interstrial bristles; each

Fig. 201. Corthylini spp., dorsal aspect of adult: a, Conophthorus resinosac; b, Gnathotrichus materiarius; c, Pseudopityophthorus minutissimus; d, Pityophthorus confinis. (After Bright 1976:213.)
bristle slightly shorter than distance between rows, spaced within a row by one to three lengths of a bristle.

Female.- Similar to male.
Distribution.- Maine to Florida and E Texas.

USA: Connecticut: Lyme. District of Columbia: Washington. Florida: Apalachicola, Oleno St. Pk. Louisiana: Covington, Zwolle. Maine: Kittery. Massachusetts: Middlesex Falls. Mississippi: Natchez, Nicholson. New Jersey: Westville. New York: Jamaica. North Carolina: Asheville, Pink Beds, Tryon. Pennsylvania: Chambersburg, Clark's Valley, Dauphin. Tennessee: Gatlinburg. West Virginia: Monongalia, Morgantown.

## Hosts.- Ostrya virginiana, Quercus spp.

Biology. - Specimens were taken from small branches in tunnels similar to those described for the genus.

Notes.- The above treatment was based on the holotype of asperulus, on the type series of gracilis, and on 183 other specimens. Blackman named gracilis from a syntypic series but labeled a male as the type; I here designate that male as the lectotype of his species.

## 8. Pseudopityophthorus hondurensis Wood

Pseudopityophthorus hondurensis Wood. 1967, Great Basin Nat. 27:42 (Holotype, male; Buenos Aires, Cortes, Honduras; Wood Coll.)
Pseudopityophthorus montanus Bright, 1972, Canadian Ent. 104:1667 (Holotype, male; Mt. Tzontehuitz, Chiapas, Mexico; Canadian Nat. Coll.); Wood, 1973, Great Basin Nat. 33:184. Synonymy
Diagnosis.- This species is distinguished from singularis Wood and tenuis Wood by the presence of minute granules on declivital interstriae 1 and 3 and by the female frons being pubescent as in the male.

Male.- Length $1.2-1.6 \mathrm{~mm}, 2.8$ times as long as wide; body color very dark brown, summit of pronotum somewhat lighter.
Frons plano-convex over a broad area, with a marginal fringe of long, yellow hair, median area punctured. Antennal club widest through segment 3 .

Pronotum 1.05 times as long as wide; sides straight and subparallel on basal half, then moderately constricted before broadly rounded anterior margin; anterior margin armed by about 14 low serrations; summit poorly developed, at middle; posterior area smooth and shining, with rather sparse, coarse, deep punctures and more numerous minute points. Subglabrous.

Elytra 1.5 times as long as wide; sides approximately straight and parallel on basal two-thirds, almost semicircularly rounded behind; striae not impressed, punctures fine, distinct but not deep, in definite rows; interstriae almost flat, smooth and shining, with a few fine lines and impressed points. Declivity convex, moderately steep; strial punctures obsolete; interstriae except 2 with a few minute setiferous granules. Vestiture mostly confined to declivity, consisting of slender, erect, hairlike, interstrial setae.

Female.- Almost indistinguishable from male, but evidently with frontal vestiture less abundant and shorter.

Distribution.- Mexico to Honduras.
MEXICO: Chiapas: Mt. Tzontehuitz, 12-VI-69, D. E. Bright. HONDURAS: Buenos Aires, Cortez, T-V-64, 2300 m . Quercus, S. L. Wood.

Biology.- Specimens were taken from a broken branch 3 cm in diameter. The habits were as described for the genus.

Notes. - The above treatment was based on the type series of 30 specimens.

## 9. Pseudopityophthorus cincinnatus (Blandford)

Pityophthorus cincinnatus Blandford, 1904, Biol. Centr. Amer., Coleopt. 4(6):242 (Holotype, female; Quiché Mts., Guatemala; British Mus. Nat. Hist.)
Diagnosis.- This species is distinguished from hondurensis Wood by the larger size, by the longer, more closely spaced declivital setae, and by the smoother, slightly wider discal interstriae.
Female.- Length 2.2 mm , about 2.8 times as long as wide; color very dark brown.

Head and pronotum missing from type.
Elytra as in hondurensis except declivity more broadly convex, interstriae 2 very feebly impressed, punctures obsolete, granules almost obsolete on lower half, vestiture distinctly longer, closer (particularly near base of declivity) and extending to base, slightly coarser.

Distribution.-Guatemala.
GUATEMALA: Quiché Mts. 7-9000 ft Champion.
Notes.- The above treatment was based on the type.

## 10. Pseudopityophthorus singularis Wood

Pseudopityophthorus singularis Wood, 1971, Brigham Young Univ. Sci. Bull., Biol. Ser. 15(3):50 (Holo-
type, male; 1 km W Las Vigas, Veracruz, Mexico; Wood Coll.)
Pseudopityophthorus acuminatus Bright, 1972, canadian Ent. 104:1671 (Holotype, male; 13 km or 8 miles NE San Cristobal de las Casas, Chiapas, Mexico; Canadian Nat. Coll.); Wood, 1973, Great Basin Nat. 33:185. Synonymy
Diagnosis.- This species is distinguished from tenuis Wood by the coarser pronotal punctures, by the longer elytral setae, by the weakly impressed male frons with slightly longer and more abundant setae, and by the subconcave female frons that lacks a median carina.

Male.- Length $1.3-1.6 \mathrm{~mm}, 3.0$ times as long as wide; color very dark brown.

Frons flattened, epistoma weakly elevated, surface indistinctly punctured; vertex bearing a sparse brush of about two dozen very long setae with tips reaching to epistoma, a few additional setae in epistomal area. Antenna as in tenuis.

Pronotum much as in tenuis, with anterior margin more broadly rounded; punctures on disc much larger, impressed points moderately abundant.

Elytra 1.8 times as long as wide; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, punctures small, distinct, in rows; interstriae almost smooth, at least three times as wide as striae, a few minute, impressed points, a few punctures toward declivity. Declivity steep, rather broadly convex; punctures of striae 1 minute, in a row, others obsolete; sutural interstriae feebly elevated, 1 , 3 , and some of lateral interstriae with sparse, minute, setiferous punctures. Vestiture of very minute strial hair and rows of widely spaced, moderately long, fine, interstrial hair on sides and declivity, almost obsolete on disc.

Female.- Similar to male except frons convex above eyes, transversely impressed above epistoma, impression extending slightly dorsad at center, surface very coarsely punctured, vestiture sparse, inconspicuous.

Distribution.- Veracruz to Chiapas.
MEXICO: Chiapas: 13 km or 8 miles NE San Cristóbal de las Casas, 15-V-69, Quercus, D. E. Bright. Veracruz: 1 km W Las Vigas 5-VII-67, No. 159, Quercus, S. L. Wood.

Biology.- Specimens were taken from the same branch as the type series of virilis Wood; the habits were similar.

Notes. - The above treatment was based on the type series of seven specimens of singularis and on the holotype and two paratypes of acuminatus.

## 11. Pseudopityophthorus tenuis Wood

Pseudopityophthorus tenuis Wood, 1959, Great Basin Nat. 19:1 (Holotype, male, I8 km or II miles NE Jacala, Hidalgo, Mexico; Snow Ent. Mus., Univ. Kansas)
Pseudopityophthorus hirsutus Bright, 1972, Canadian Ent. I $04: 1668$ (Holotype, male; 8 km or 5 miles SE Teopisca, Chiapas, Mexico; Canadian Nat. Coll.); Wood, 1973, Great Basin Nat. 33:I85. Synonymy
Diagnosis.- This species is distinguished from asperulus (LeConte) by the pubescent male frons, the presence of a small, median carina on the female frons, and by the smoother surface and finer punctures on the pronotum and elytra.

Male.- Length $1.2-1.4 \mathrm{~mm}, 3.0$ times as long as wide; color very dark brown.

Frons as in asperulus except with a conspicuous tuft of long, yellow hair. Pronotum as in asperulus except surface smoother, punctures smaller. Elytra as in asperulus except more brightly shining, surface evidently smoother, punctures finer.

Female.- Similar to male except frons glabrous, less extensively flattened, a small median carina at upper level of eyes.

Distribution.-Hidalgo and Veracruz to Chiapas.

MEXICO: Chiapas: 8 km or 5 miles SE Teopisca, 9-VII-69, Quercus, D. E. Bright. Hidalgo: 17 km NE Jacala, 22-VI-53, Quercus, S. L. Wood. Veracruz: It km E Huatasco, 7-VII-67, 250 m , No. 172, Qucreus, S. L. Wood.

## Hosts.- Quercus sp.

Biology.- Specimens were taken from cut branches 5 cm in diameter. The habits were as described for the genus.

Notes.- The above treatment was based on 7 paratypes of tenuis, on the holotype and 2 paratypes of hirsutus, and on 22 other specimens.

## 12. Pseudopityophthorus pubescens Blackman <br> Fig. 202

Pseudopityophthorus pubescens Blackman, I931, J. Washington Acad. Sci. 2I:229 (Holotype, male; Tryon, North Carolina; U.S. Nat. Mus., 43424)
Diagnosis.- This species is distinguished from others in the genus by the shallowly concave male frons and by the very long, hairlike elytral vestiture that is in rows.

Male.- Length $1.8-2.0 \mathrm{~mm}, 2.8$ times as long as wide; color dark brown.

Frons broadly, rather shallowly concave from epistoma to vertex; surface shining, obscurely punctured, a few short setae in concavity; vertex above concave area bearing a dense brush of long, yellow hair, longest setae exceeding epistomal margin.

Pronotum 1.17 times as long as wide; general sculpture as in asperulus (LeConte) except posterior areas with moderately abundant, short, hairlike pubescence.

Elytra 1.7 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, punctures small, somewhat obscure; interstriae irregular, four to six times as long as wide. Declivity steep, convex; surface smooth, with obscure points, setiferous punctures confused. Vestiture on disc hairlike, in rows, of short, semirecumbent hair, and long, erect, interstrial bristles, each bristle at least twice as long as distance between rows, similarly spaced within a row; declivital setae on central area short, almost scalelike.

Female.- Similar to male except frons more shallowly, less extensively impressed.

Distribution.-Virginia and North Carolina.
USA: North Carolina: Asheville, 8-VIII-55, Quercus borealis. E. P. Merkel; Tryon, Hopk. U.S. 3040, Castanca dentatu, W. F. Fiske. Virginia: E. Woodford, I-X-21, Quercus rubra, R. St. George: Carter Bridge, Quercus alba.

Hosts.- Quercus alba, Q. borealis, Q. rubra, Castanea dentata.

Biology. - Unknown except for the host records.

Notes.- The above treatment was based on the type series of 11 specimens and on 6 other specimens.

## 13. Pseudopityophthorus fagi Blackman Fig. 202

Pseudopityophthorus fagi Blackman, 1931, J. Washington Acad. Sci. 21:228 (Holotype, male; Morgantown, West Virginia; U.S. Nat. Mus., 43423)
Diagnosis.- This species is distinguished from asperulus (LeConte) by the conspicuously pubescent male frons, by the shorter interstrial bristles, and by the very slightly smoother elytral surface, with the impressed points more conspicuous.

Male.- Length $1.4-1.5 \mathrm{~mm}, 3.0$ times as long as wide; color dark brown.

Frons as in asperulus except margins of flattened area more abrupt, pubescence rather abundant, fine, very long. Pronotum 1.14 times as long as wide, as in asperulus except basal half with sparse pubescence, particularly on basal margin. Elytra 1.7 times as long as wide, 1.6 times as long as pronotum; as in asperulus except strial punctures smaller, surface smoother, with impressed points more abundant, deeper; interstrial bristles shorter, slightly longer than strial setae, each about two-thirds as long as distance between rows, more closely spaced within a row: declivity with very obscure, minute granules.
Female.- Similar to male except frons sparsely pubescent (not seen).

Distribution.- Pennsylvania and West Virginia.
USA: Pennsylvania: Newton, 13-111-15, Fagus atropunicea, W. P. Adams. West Virginia: Midland Farm, Morgantown. 26-X1-96, Hopk. W. Va. 7142a, Fagus, A. D. Hopkins.

## Host.- Fagus grandifolia.

Biology.- Only the host record of this rare species is known.

Notes. - The above treatment was based on the type series of six specimens and on three other specimens.

## 14. Pseudopityophthorus agrifoliae Blackman

Fig. 202
Pseudopityophthorus agrifoliae Blackman, 1931, J. Washington Acad. Sci. 21:230 (Holotype, male; Golden Gate Park, San Francisco, California; U.S. Nat. Mus., 43426)

Dragnosis. - This species is distinguished from fagi Blackman by the larger size, by the more finely punctured pronotal dise, and by the larger, more definite rows of setae on
declivital interstriae 1 and 3, with those on 2 entirely absent.

Male.- Length $1.5-1.9 \mathrm{~mm}, 2.9$ times as long as wide; color dark brown.

Frons broadly flattened from epistoma to vertex, surface subshining, punctures shallow, moderately coarse, rather close; vestiture of fine, very long hair, rather sparse in central area, abundant on upper and lateral margins to epistoma.

Pronotum 1.14 times as long as wide; as in fagi except punctures on posterior areas finer, impressed points larger, vestiture on disc less evident.

Elytra 1.7 times as long as wide, 1.5 times as long as pronotum; as in fagi except striae evidently obsolete in some specimens, strial and interstrial setae not always distinguishable: setae on declivital interstriae 1 and 3 slightly larger, in definite rows, those on 2 obsolete, but minute strial setae present (some setae on interstriae 2 present in fagi and those on 1 and 3 smaller).

Female.- Similar to male in all respects.
Distribution.- California and Arizona.
USA: Arizona: Madera Canyon, 24-VIII-58, Quercus, S. L. Wood. California: Golden Gate Park, San Francisco, 20-1V-99, Q. agrifolia, A. D. Hopkins; Mill Valley, Marin Co., 4-1V-57, Q. wislizeni, H. B. Leech; Santa Lucia Range, 5-VII-54, 600 m , agrifolia, O. Bryant; Big Pine Pk., S-IV-40, Q. kelloggi, C. R. Bruck.

Hosts.- Quercus agrifolia, Q. kelloggii, Q. wislizenii, Q. sp.

Biology. - Specimens were taken from cut branches.

Notes. - The above treatment was based on the holotype and on 92 other specimens. The Arizona specimen's declivity is more strongly convex and the elytral setae very slightly stouter, but it almost certainly belongs to this species.

## 15. Pseudopityophthorus limbatus Eggers

Pseudopityophthorus limbatus Eggers, 1931, Ent. Blätt. 26:169 (Holotype, female; "R.d.M.," Mexico; deposited in Eggers Coll. but apparently now on loan to Schedl)
Pseudopityophthorus micans Wood, 1967, Great Basin Nat. 27:44 (Holotype, male; 96 km or 60 miles W Durango, Durango, Mexico; Wood Coll.); Wood, 1975, Great Basin Nat. 35:394. Synonymy
Diagnosis. - This unique species is distinguished from others in the genus by the large size, by the obsolete striae, with confused discal punctures and minute, fine, strial hair,
and by the smooth, polished elytral declivity normally devoid of punctures and setae.

Male.- Length $2.0-2.5 \mathrm{~mm}, 2.7$ times as long as wide; color dark brown.

Frons plano-convex on three-fourths of a circle, smooth and shining at center, with a marginal fringe of closely placed, long, erect, hairlike setae, marginal pubescent area closely, finely granulate-punctate. Antennal club widest through segment 3 .

Pronotum 1.1 times as long as wide; sides weakly arcuate, almost parallel on basal half, then moderately constricted before rather narrowly rounded anterior margin; anterior margin armed by about 14 small teeth; summit indefinite; posterior area behind summit smooth and shining with rather abundant fine punctures and minute points. Glabrous except at margins.

Elytra 1.6 times as long as wide; sides straight and subparallel on basal two-thirds, abruptly narrowed at posterolateral angles, rather narrowly rounded behind; elytral punctures largely limited to anterior twothirds of disc, fine, confused except for striae 1 ; surface smooth and shining but marked with a few fine lines. Declivity abrupt, with apical and sutural area somewhat produced posteriorly; surface smooth and shining. Glabrous except for a few setae at anterolateral angles.

Female.- Similar to male, though frons finely, deeply punctured except for a narrow median line; frontal vestiture sparse, scattered; and declivital punctures minute but evident.

Distribution.- Durango and Hidalgo to Oaxaca.
MEXICO: Durango: 64 km , No. 15 , and 96 km , No. 22, W Durango, 5 -V1-65, 2200-2500 m: 5 km W El Salto, 7 -V1- $65,2500 \mathrm{~m}, \mathrm{No} .32$. Hidalgo: 31 km E Tulancingo, 12-V1-67, 2200 m , No. 15. Michoacán: 53 km E Morelia, 14-Vl-65, 3000 m , No. $51 ; 9 \mathrm{~km}$ S Carapan, 18 -V1-65, 2200 m , No. 78. Oaxaca: Nochixtlán, 16-V1-67. Tlaxcala: 17 km N Tlaxco, 9-V11-67, 2900 m , No. 178. All were taken by me from Quercus.

Hosts. - Quercus spp.
Biology. - Specimens were taken from boles and limbs of recently cut or fallen trees. The habits were as described for the genus.

Notes. - The above treatment was based on the holotype of limbatus, on the type series of 57 specimens of micans, and on 28 other specimens.

## 16. Pseudopityophthorus minutissimus (Zimmermann) Figs. 201, 202, 207

? Tomicus (?) pusillus Harris, 1837. Trans. Nat. Hist. Soc. Hartford 1:82
Crypturgus minutissimus Zimmermann, 1868, Trans. Amer. Ent. Soc. 2:143 (Lectotype, male; Carolina; Mus. Comp. Zool., 1007, present designation)
Pseudopityophthorus minutissimus: Swaine, 1918, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(2):93
Diagnosis.- This species is distinguished from others in the genus by the reticulate frons and pronotal dise in both sexes, by the very fine, confused elytral punctures, and by the uniformly short, confused, slender elytral setae.

Male.- Length $1.5-1.8 \mathrm{~mm}, 2.74$ times as long as wide; color dark brown.

Frons very broadly planoconcave from epistoma to vertex; surface strongly, finely reticulate, small punctures confined to marginal areas; lateral and upper margins ornamented by a dense brush of long, yellow hair; epistomal margin feebly emarginate. Antennal club comparative small, sutures 1 and 2 moderately arcuate.

Pronotum 1.1 times as long as wide; sides on posterior half very weakly arcuate, subparallel, feebly constricted just before broadly rounded anterior margin; anterior margin armed by about 16 coarse serrations; summit broad, slightly in front of middle; anterior slope rather coarsely asperate; posterior areas finely reticulate (obscure in some specimens), finely, rather closely punctured, impressed points not evident. Usually glabrous.

Elytra 1.66 times as long as wide, 1.44 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; surface shining, minutely somewhat irregular, punctures fine, confused, shallow, rather close. Declivity steep, convex; surface smoother and punctures much finer than on disc. Vestiture of short, fine, confused, reclining, moderately stout hair of uniform length, setae often very slightly stouter on declivity.

Female.- Similar to male except frons planoconvex on a smaller area, vestiture rather sparse, much shorter, confined to a smaller area; serration on anterior margin of pronotum usually finer.

Fig. 202. Pseudopityophthorus spp., antennae and tibiae: 1-2, asperulus; 3, fagi; 4, pubeseens; 5, 5a, granulatus; 6-7, minutissimus; 8, agrifoliae; 9-10, 13, pruinosus; 11-12, yavapaii; 14, pubipennis; 15, opacicollis. (After Blackman 1938:227.)

Distribution.- Minnesota and Maine to Louisiana and Florida.

USA: Arkansas: Camden. District of Columbia: Washington. Florida: Crescent City, Indian River, Oleno St. Pk., Sanford. Georgia: Brunswick, Cornelia. Iowa: "Ia." Kansas: Lawrence. Louisiana: Greenwell Springs. Maine: Wales. Maryland: Beltsville, Berwin, Bladensburg, Chevy Chase, College Park, Harper's Ferry, Oakland. Massachusetts: Middlesex Falls. Michigan: Detroit. Minnesota: Houston Co., Winona Co. Mississippi: Agricultural College, Meridian. Missouri: Dent Co. New Jersey: Alpine, Brunswick, Clementon, Denville, Grenlock, Montclair, Newark, Orange. New York: Ithaca, Long Island, Syracuse, West Point. North Carolina: Pink Beds, Tryon. Pennsylvania: Chambersburg, Frankford, Lazareth, Lehigh Gap, Mt. Alto, Perry Co., Sullivan Co. South Carolina: Chicora, Paris Mt., Spartinsburg. Virginia: Falls Church, Georgetown, Mt. Vernon. West Virginia: Dellslow, Laurel Hill, Monongalia Co., Morgantown, Pocahontas Co., Wood Co. Wisconsin: Clintonville.

Hosts.- Quercus muehlenbergii, Q. rubra, $Q$. velutina, $Q$. spp. Rare or probably accidental in other hosts.

Biology.-Specimens were taken from cut or broken limbs and branches. The habits are as described for the genus.

Notes. - Of the two male syntypes of minutissimus in the LeConte collection I here designate the first as the lectotype of Zim mermann's species. This specimen was compared directly to several specimens in my collection that were used for the above treatment; 394 specimens were examined.

The species named Tomicus (?) pusillus Harris is unknown. It was assumed by LeConte (1868:143) to be identical to minutissimus; however, the original description indicated that the elytral declivity of the type was scabrous and that the hairs and bristles on the elytral declivity were in rows. Neither of these features fit minutissimus.

## 17. Pseudopityophthorus comosus Bright

Pseudopityophthorus comosus Bright, 1972, Canadian Ent. 104:1670 (Holotype, male; Highway 131, 178 km S Oaxaca, Oaxaca, Mexico; Canadian Nat. Coll., 12629)
Diagnosis.- This species is distinguished from limbatus Eggers by the longer coarser vestiture, particularly on the declivity, and by the presence of minute declivital punctures.

Male.- Length $2.2-2.5 \mathrm{~mm}, 2.7$ times as long as wide; color dark brown.

All features essentially as in limbatus except elytral vestiture. Ground setae at least twice as long and slightly more abundant than in limbatus; posterior half of elytra with erect interstrial setae slightly longer and distinctly coarser than hair of ground cover. Declivity with minute setiferous punctures.

Female.- Similar to male except frons as in female limbatus.

Distribution.- Oaxaca.
MEXICO: Oaxaca: Highway 131, at $115 \mathrm{~km}, 178 \mathrm{~km}$, 184 km S Oaxaca, 11-30-V-71, 2000-2500 m, Quercus, D. E. Bright.

Notes.- The above treatment was based on a male and a female paratype.

Some series of limbatus have the elytral vestiture intermediate between these two forms. Because the known distributions are separated by a gap of more than 200 km , additional collecting will be necessary in Oaxaca to determine whether geographical races or distinct species are represented by these names.

## 18. Pseudopityophthorus squamosus Bright

Pseudopityophthorus squamosus Bright, 1972, Canadian
Ent. 104:1670 (Holotype, female; 9 miles or 14 km W La Ciudad, Durango, Mexico; Canadian Nat. Coll., 12628)
Diagnosis.- This species is distinguished from limbatus Eggers by the sculpture of the frons, by the reticulate pronotum, by the smaller antennal club with straight sutures, by the densely, minutely punctured elytral declivity, and, when not abraded, by the presence of declivital scales.

Male.- Length $2.1-2.4 \mathrm{~mm}, 2.6$ times as long as wide; color reddish brown.

Frons transversely impressed, almost flat, to upper level of eyes, a conspicuous, blunt, median, transverse elevation above eyes; surface subreticulately, finely punctate-granulate from epistoma to vertex except elevation almost smooth; vestiture of about two dozen long, yellow, hairlike setae arising on vertex, a few additional setae on lower areas.

Pronotum as in limbatus except surface of posterior areas strongly reticulate.

Elytra as in limbatus except declivity finely, rather densely punctured; recently emerged specimens with rather abundant, small scales.

Female.- Similar to male except long hair on vertex absent.
Distribution.- Durango to Sinaloa.
MEXICO: Durango: 29 km W El Salto, 7 -VI-65, 2500 m, No. 36, S. L. Wood; 59 km W El Salto, 10-VI-64, H. F. Howden; 15 km W La Ciudad, II-VI-64, L. A. Kelton. Sinaloa: 8 km N Mazatlán, 14-VllI-64, H. F. Howden.
Notes.- The above treatment was based on two topotypic paratypes and on four other specimens. The four specimens from El Salto were inadvertently designated as paratypes of micans Wood and compared to the types of squamosus rather than to true micans. On the basis of this error squamosus was incorrectly placed in synonymy.

## 19. Pseudopityophthorus pruinosus (Eichhoff)

 Fig. 202, 207Pityophthorus pruinosus Eichhoff, 1878, preprint of Mém. Soc. Roy. Sci. Liége (2)8:198 (Lectotype. male; published as Carolina, labeled "Am. bor.," no. "Il"; U.S. Nat. Mus., 4562, present designation)
Pseudopityophthorus pruinosus: Swaine, 1918, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. I4(2):94
Pityophthorus tomentosus Eichhoff, 1878. preprint of Mém. Soc. Roy. Sci. Liége (2)8:201 (Holotype, sex?: America borealis; presumably lost with Hamburg Mus.); Blackman, 193I, J. Washington Acad. Sci. 21:225. Synonymy?
Pityophthorus querciperda Schwarz, 1888, Proc. Ent. Soc. Washington I:56 (Syntypes; New York to Florida; U.S. Nat. Mus.); Eichhoff, 1896. Proc. U.S. Nat. Mus. 18:609. Synonymy

Pseudopityophthorus pulvereus Blackman, 1931, J. Washington Acad. Sci. 21:232 (Holotype, male; Chiricahua Reserve, Arizona; U.S. Nat. Mus., 43427); Wood, 1973, Great Basin Nat. 33:I85. Synonymy
Pseudopityophthorus tropicalis Wood, 1967, Great Basin Nat. 27:43 (Holotype, male; Zamorano, Morazán, Honduras; Wood Coll.); Wood, 1973, Great Basin Nat. 33:185. Synonymy
Pseudopityophthorus convexus Bright, 1972. Canadian Ent. 104:1672 (Holotype, male; 184 km or 115 miles S Oaxaca, Oaxaca, Mexico; Canadian Nat. Coll., 12632); Wood, 1973, Great Basin Nat. 33:185. Synonymy
Diagnosis.- This species is distinguished from minutissimus (Zimmermann) by the larger average size, by the larger elytral punctures, by the stouter, almost scalelike
elytral setae of uniform length, a row of declivital scales on interstriae 1 and 3 sometimes being erect and very slightly longer, and by the male frons being plano-convex, with the vestiture usually slightly longer and more abundant.

Male.- Length $1.5-1.8 \mathrm{~mm}, 2.8$ times as long as wide; color dark brown.

Frons weakly convex except distinctly, transversely impressed above epistoma; finely punctured on marginal areas; margins ornamented by a dense brush of long, yellow hair, longest setae arising on vertex exceeding epistomal margin. Antennal clu's as in minutissimus.

Pronotum as in minutissimus except posterior areas smooth, shining, not at all reticulate, impressed points rather abundant, conspicuous, punctures small, slightly larger than in minutissimus.
Elytra as in minutissimus except declivity more broadly convex, slightly flattened, discal punctures coarser, closer, interstriae little if any wider than punctures, setae very slightly longer, much stouter, laterally compressed; punctures on declivity smaller and setae stouter than on disc, some specimens in any series with setae on interstriae 1 and 3 slightly longer, erect.

Female.- Similar to male except frons more distinctly convex, transverse impression weaker, vestiture sparse, shorter, fine.

Distribution.- Michigan and New York to Honduras and Florida.

USA: Arizona: Chiricahua Reserve, Prescott, Santa Catalina Mts. Arkansas: Camden. District of Columbia: Washington. Florida: Crescent City, Gainesville, La Belle, Mariana, Oleno St. Pk., Orlando. Georgia: Atlanta, Clayton, St. Catherine Island. Louisiana: Covington. Maryland: Beltsville, Bladensburg. Michigan: Seney. Mississippi: luka, Laurel, Meridian, Nicholson, Summerland, Trimcane Swamp. New Jersey: Newark. New York: New York, Peekskill, Watermill. North Carolina: Asheville, Pink Beds, Tryon. Pennsylvania: Chester Hill, Lazareth, Rydal. South Carolina: Clemson, Spartinsburg. Tennessee: Knoxville. Texas: Kirbyville, Montell. West Virginia: Dellslow, Kanawha Station, Morgantown, Roosevelt, Wood Co. MEXICO: Durango: 37 km and 64 km W Durango, 48 km SW El Salto. Michoacán: Morelia, Quiroga. Oaxaca: Nochixtlán, 184 km S Oaxaca. Sinaloa: Copala. Veracruz: Huatasco. GUATEMALA: Volcán de Agua. HONDURAS: Zamorano.

Hosts.- Quercus hypoleuocoides, Q. marilandica, Q. nigra, Q. spp.

Biology.- Specimens were taken from cut and broken limbs and branches. The habits are as described for the genus.

Notes.- The above treatment was based on the holotypes of pulvereus, tropicalis, and convexus, on syntypes of pruinosus and querciperda, and on 385 other specimens. The male syntype of pruinosus in the U.S. National Museum is here designated the lectotype of Eichhoff's species.

## 20. Pseudopityophthorus festivus Wood

Pscudopityophthorus festicus Wood, 1974, Brigham Young Univ. Sci. Bull., Biol. Ser. 19(1):55 (Holotype, male; 11 km NE Copala, Sinaloa, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from pruinosus (Eichhoff) by the planoconcave male frons, by the more strongly impressed elytral declivity, by the more coarsely punctured elytral surface, and by the very different elytral vestiture.

Male.- Length $1.6-1.8 \mathrm{~mm}, 2.8$ times as long as wide; color dark brown.

Frons broadly plano-concave from epistoma to vertex; surface smooth, shining in central area, marginal areas finely punctured and bearing a dense tuft of long, yellow hair. Antenna as in pruinosus.

Pronotum 1.2 times as long as wide, as in pruinosus.

Elytra 1.6 times as long as wide, 1.3 times as long as pronotum; outline as in pruinosus; surface smooth, shining, punctures moderately coarse, shallow, confused, very close, width of interspaces about equal to diameter of punctures. Declivity steep, flattened; moderately elevated at suture, a moderately strong sulcus in area of interstriae 2 , lateral convexities rounded; punctures minute. Ground vestiture of fine, short, stout, reclining setae; erect scales in interstrial rows except obsolete on lower half of 2 on declivity, each scale about as long as distance between rows, similarly spaced within a row, each about four to eight times as long as wide.

Female.- Similar to male except frons plano-convex, pubescence sparse, fine, much shorter.

Distribution.- Sinaloa.
MEXICO: Sinaloa: 11 km or 7 miles NE Copala, 22 -VII-53, Quercus, S. L. Wood.

Biology.-Specimens were taken from a broken branch.

Notes.- The above treatment was based on the type series of four specimens.

## 21. Pseudopityophthorus opacicollis Blackman

Fig. 202
Pseudopityophthorus opacicollis Blackman, 1931, J. Washington Acad. Sci. 21:235 (Holotype, male; Santa Catalina Mts., Arizona; U.S. Nat. Mus., 43429)

Pscudopityophthorus acsculinus Bright, 1972, Canadian Ent. 104:1672 (Holotype, female; 112 km or 70 miles N Oaxaca, Oaxaca. Mexico; Canadian Nat. Coll.); Wood, 1973, Great Basin Nat. 33:185. Synonymy
Diagnosis.- This species is distinguished from festivus Wood by the larger size, by the more feebly impressed elytral declivity, and by the absence of longer, erect, interstrial setae on even-numbered interstriae.

Male.- Length $1.8-2.2 \mathrm{~mm}, 2.7$ times as long as wide; color dark brown.

Frons moderately convex above, transversely impressed on lower third, a slight callus at upper margin of impression; surface smooth and shining on lower median area, punctured in marginal areas; margins ornamented by a dense brush of long, yellow hair. Antennal club as in pruinosus (Eichhoff).

Pronotum 1.14 times as long as wide; about as in pruinosus except more distinctly constricted on anterior third, posterior areas more closely punctured.

Elytra 1.7 times as long as wide, 1.5 times as long as pronotum; sides straight and parallel on basal two-thirds, rather narrowly rounded behind; disc as in festivus except punctures smaller. Declivity steep, slightly flattened; sulcus on interstriae 2 feeble; punctures smaller than on disc. Vestiture of moderately abundant, recumbent, rather stout,
short ground cover, and rows of longer, erect setae on even-numbered interstriae beginning about middle of disc; longest setae about two to three times as long as ground vestiture, almost hairlike on disc, becoming scalelike on declivity, those on 9 hairlike throughout.

Female.- Similar to male except frons less strongly convex above, less strongly impressed below, vestiture sparse, shorter.

Distribution.-Arizona to Chiapas.
USA: Arizona: Madera Canyon, 24-VIII-58, Quercus, S. L. Wood; Miller Canyon, 22-VIl1-58, Quercus, S. L. Wood: Santa Catalina Mts., 28-VII-13, Blackjack oak, Hopk. U.S. 10519a, M. Chrisman. MEXICO: Chiapas: Mt. Tzontahuitz, 13-VI-69, Quercus, D. E. Bright. Durango: 56 km SW El Salto, 23-VII-53, Quercus, S. L. Wood. Hidalgo: 16 km E Pachuca, 10-VI-67, 2700 m , No. 5. Quercus, S. L. Wood; 8 km W Tulacingo, 11-VI67, 2400 m , No. II, Quercus, S. L. Wood. Oaxaca: Oaxaca, 18-V-71, 2800 m , Quercus, D. E. Bright. Tlaxcala: 17 km N Tlaxco, 9-V11-67, 2900 m , No. 179, Quercus, S. L. Wood.

Hosts.- Quercus spp.
Biology.- Specimens were taken from boles, limbs, and branches of cut and broken trees. The habits are essentially as described for the genus.

Notes.- The above treatment was based on the type series of both aesculinus and opacicollis, and on 44 other specimens.

## 22. Pseudopityophthorus pubipennis (LeConte)

Fig. 191, 202, 208-209
Bostrichus pubipennis LeConte, 1860, Rept. Expl. Surv. Railroad Mississippi River-Pacific Ocean 9(1):59 (Lectotype, female; San Jose, California; Mus. Comp. Zool., 2022, present designation)
Pseudopityophthorus pubipennis: Swaine, 1918, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(2):93.
Diagnosis.- This species is distinguished from yavapaii Blackman by the less numerous, much stouter elytral bristles, which are absent on declivital interstriae 2 , and, usually, by the presence of minute setae on the pronotal disc.

Male.- Length 1.7-2.5 mm, 2.7 times as long as wide; color dark brown.

Frons broadly flattened from epistoma to vertex, a narrow, abrupt, transverse impres-
sion above epistoma, upper margin of impression with a moderately strong median callus; surface shining, punctures mostly in marginal areas; vestiture mostly on margins, of abundant, long, yellow hair, tips of longest setae on vertex exceeding epistoma. Antennal club moderately large, oval, segment 1 very small, sutures 1 and 2 strongly arcuate, 2 reaching middle.

Pronotum 1.14 times as long as wide; essentially as in opacicollis Blackman.

Elytra 1.6 times as long as wide, 1.45 times as long as pronotum; sides straight and parallel on basal two-thirds, rather broadly rounded behind; punctures on disc abundant, small, confused, surface shining, subrugulose. Declivity steep, rather broadly convex; sculpture about as on disc, with punctures smaller, surface smoother, numerous impressed points evident. Vestiture consisting of ground cover of abundant, rather short, subplumose setae, and of long, slender, interstrial bristles, bristles sparse on dise, absent on declivital interstriae 2.

Female.-Similar to male except frons without transverse impression or callus, vestiture fine, sparse, short.

## Distribution.- Oregon to California.

USA: California: Alameda Co., Bass Lake, Berkeley, Calaveras Co., Contra Costa Co., Del Monte, Del Norte Co., El Dorado Co., Grass Valley, Halsey, Humboldt Co., Kaweah, Kern Co., Lafayette, Lake Co., Los Angeles, Los Gatos, Madera Co., Mendocino Co., Montecito, Monterey Co., North Fork, Oakland, Palo Alto, Pasadena, Placer Co., Riverside Co., Sacramento, Salyer, San Bernardino Co., San Diego, San Rafael, San Francisco, Santa Barbara Co., Santa Clara Co., Santa Cruz, Shasta Co., Sylvania, Tapia Pk., Ventura Co., Yolo Co., Yosemite Valley, Yuba Co. Oregon: Ashland, Corvallis, Forest Grove, Hood River, Jacksonville, Portland.

Hosts.- Quercus agrifolia, Q. garrayana, and Q. kelloggii.

Biology.- Specimens were taken from boles, limbs, and branches. The habits are as described for the genus.

Notes.- The above treatment was based on 435 specimens 2 of which were compared to the 4 syntypes in the LeConte collection. The first syntype, a female, is in better condition than the others and is here designated as the lectotype of pubipennis.

## 23. Pseudopityophthorus yavapaii Blackman

 Fig. 202Pseudopityophthorus yavapaii Blackman, 1931, J. Washington Acad. Sci. 21:233 (Holotype, male; Prescott N.F., Arizona; U.S. Nat. Mus., 43428)
Diagnosis.- This species is distinguished from pubipennis (LeConte) by the more abundant, more slender elytral bristles, which also occur on declivital interstriae 2 , and by the glabrous pronotal disc.

Male.- Length 1.7-2.6 mm, 2.7 times as long as wide; color dark brown.

Frons and pronotum essentially as in pubipennis except pronotal disc glabrous.

Elytra as in pubipennis except elongate interstrial bristles more numerous, more slender, some bristles on declivital interstriae 2.

Female.- Similar to male except frons slightly convex, more coarsely punctured, impression and callus obscure or absent, vestiture fine, sparse, short.

Distribution.-Arizona to Chihuahua.
USA: Arizona: Chiricahua Mts., Huachuca Mts., Paradise, Patagonia, Prescott, Santa Catalina M1ts., Santa Rita Mts. MEXICO: Chihuahua: 24 km NW Chihuahua.

Hosts.- Quercus hypoleucoides, and $Q$. spp.

Biology.- The bole, limbs, and branches of cut or brokn host material were selected for attack. The habits were as described for the genus.

Notes.- The above treatment was based on 2 paratypes and on 215 other specimens. The holotype was also examined.

## Genus CONOPHTHORUS Hopkins

Conophthorus Hopkins, 1915, J. Washington Acad. Sci. 5:430 (Type-species: Pityophthorus coniperda Schwarz, original designation)
Diagnosis.- This genus is distinguished from Pityophthorus Eichhoff by the larger size, by the stout body form, by the aseptate antennal club, by the pronotum that has an indefinite summit on the basal third and the asperities continuing to or near the base in
the lateral areas, and by the monogamous, cone-infesting habit (one apparent exception).

Description.- Length 2.2-4.1 mm, 2.3-2.4 times as long as wide; color brown to black.

Frons simple, essentially convex, sparsely punctured, vestiture sparse, sexual differences inconspicuous. Eye emarginate, finely faceted. Antennal scape slender, rather long; funicle 5 -segmented; club oval, with lateral constrictions at sutures, sutures 1 and 2 aseptate, conspicuously marked by grooves and setae. Pronotum longer than wide, indefinite summit on basal third, anterior slope with numerous asperities, asperities descending in height gradually posterolaterally, some extending to or near base in lateral areas. Elytra with punctures in more or less definite strial and interstrial rows, declivity sulcate, rather simple. Vestiture hairlike. Tibiae similar to Pityophthorus.

Distribution.-S Canada to Mexico; 14 species are known.

Biology.- These monogamous species infest cones of the genus Pinus, except that banksianae McPherson infests twig terminals. Other species are apparently able to survive in twigs when cones are not available. Young cones are usually attacked from May to midJuly in the second year of their growth. When the beetles are under stress, first-year cones are sometimes attacked. In severe infestations more than half the seed production may be destroyed. The larvae develop in the cones and the young adults do not emerge from them until spring. Occasional specimens may not emerge until the second spring.

Notes.- Character diversity in this genus is limited. Characters are poorly developed and variable, making the separation of some species extremely difficult. It is suspected that one or more sibling species occur in the western forms, but their recognition must await detailed biological studies.

Key to the Species of Conophthorus

1. Declivital striae 1 and 2 with punctures moderately coarse, interstriae 2 not more than twice as wide as 1 , less strongly impressed, surface gradually ascending to striae 3 , punctures on interstriae 3 usually not granulate; in pinyon pines

- Declivital striae 1 with punctures largely or entirely obsolete, those on 2 usually very small to obsolete, interstriae 2 three or more times as wide as 1 , rather strongly impressed, lateral summit at middle of 3, usually armed by small tubercles; on other pines, not pinyon

2(1). Discal interstriae about four times as wide as striae, strial punctures on declivity much smaller than on disc; color uniformly very dark brown to almost black; California to W Utah; Pinus monophylla; $2.7-3.1 \mathrm{~mm}$

1. monophyllae Hopkins

- Discal interstriae about two and one-half times as wide as striae, strial punctures on declivity only slightly smaller than on disc; elytra reddish brown.
3(2). Punctures on pronotum and elytra averaging smaller; declivital interstriae 2 less strongly impressed; frons somewhat flattened; Arizona to Hidalgo; Pinus cembroides; $2.2-2.5 \mathrm{~mm}$

2. cembroides Wood

- Punctures on pronotum and elytra averaging larger; declivital interstriae 2 more distinctly impressed; frons more strongly convex; Utah and Colorado to Arizona and W Texas; Pinus edulis; 2.3-3.0 mm

3. edulis Hopkins

4(1). Elytral declivity with about 6-12 small tubercles more or less uniformly distributed from base to apex of interstriae 1; male declivity with suture and lateral convexities subequal in height

- Elytral declivital interstriae I unarmed on at least lower two-thirds, one tubercle sometimes present just before apex; lateral convexities on declivity much higher than suture, at least in male

5(4). Elytral declivity not as steep, without minute impressed points, interstriae 1
armed by about $6-8$ small tubercles; California; Pinus radiata; 3.3-4.1 mm
4. radiatae Hopkins

- Declivity much steeper, with numerous, minute, impressed points, interstriae 1 armed by about 8-12 small tubercles

6(5). Smaller; punctures on declivital striae 2 slightly larger, more closely, more regularly spaced; punctures on discal interstriae averaging closer, more regular; elytral setae slightly shorter

- Mostly larger; punctures on declivital striae 2 slightly smaller, not as close, spacing somewhat irregular; punctures on discal interstriae usually not as close, spacing more irregular; elytral setae slightly longer
7(6). Smaller; declivity more strongly arched, particularly at suture on middle half, sulcus not as deep, slightly narrower; pronotal and elytral punctures distinctly larger, deeper, interstriae less than three times as wide as striae; transverse frontal impression not as strong; Missouri; Pinus echinata; 2.3-2.5 mm 5. echinatae Wood
- Larger; declivity more weakly arched, particularly on middle half, sulcus deeper, wider; pronotal and elytral punctures smaller, interstriae usually four times as wide as striae; transverse frontal impression slightly deeper; Minnesota and Maine to North Carolina; Pinus strobus; 2.4-3.0 mm

6. coniperda (Schwarz)

8(6). Average size smaller; elytral setae slightly longer; breed in twigs; Minnesota
and Wisconsin to W Ontario and Michigan; Pinus banksiana; 2.4-2.9 mm .......
7. banksianae McPherson

- Average size larger, 95 percent of them larger than 3.0 mm ; elytral setae slightly shorter; breed in cones; Minnesota and New Hampshire to New Jersey, West Virginia, and Wisconsin; Pinus resinosa; $2.6-3.4 \mathrm{~mm}$

8. resinosae Hopkins

9(4). Declivity very strongly, rather narrowly impressed, denticles on lateral summit larger; punctures on discal striae small, interstriae four to six times as wide as striae; discal interstriae without impressed points; female frons with profile convex, without an epistomal tubercle; Puebla; Pinus; 3.3-4.1 mm
9. mexicanus Wood

- Declivity moderately impressed, lateral denticles smaller; punctures on discal striae larger, interstriae about three times as wide as striae
10(9). Declivity strongly, broadly impressed, tubercles on 3 larger, punctures on striae 2 rather coarse; disc smooth, punctures larger, somewhat confused; body stouter, elytra 1.4 times as long as wide; Hidalgo and Mexico to Puebla; Pinus leiophylla; 3.3-3.8 mm
- Declivity much less strongly impressed, punctures on striae 2 smaller, less regular, tubercles on 3 small to obsolete; strial punctures on disc in distinct regular rows, interstrial punctures either smaller or widely spaced; body more slender, elytra at least 1.5 times as long as wide
11(10). Profile of frons convex, female epistoma without a median, subtuberculate, low elevation (a feeble impression on upper half in michoacanae); average size larger
- Profile of frons weakly concave from epistoma to upper level of eyes, female with a median, subtuberculate elevation (obscure or absent in male ponderosae); elytral disc without impressed points; average size smaller
12(11). Interstriae on basal half of disc usually wrinkled, punctures much more abundant, confused; declivity much steeper, more strongly arched, impression narrower; frons more evenly convex; body stouter; Arizona; Pinus engelmannii; $3.7-3.9 \mathrm{~mm}$

11. apachecae Hopkins

- Interstriae on basal half of disc smooth, punctures sparse, confused only at base; declivity more gradual, less strongly arched, impression much broader; frons with a weak, transverse impression on upper half; body more slender; Michoacán; Pinus michoacana; 3.9-4.2 mm

12. michoacanae Wood

13(11). Male frons never with a median carina, epistomal tubercle reduced to obsolete; declivital striae 2 usually with punctures to near its apex; declivital sulcus usually deeper, narrower; British Columbia and Montana to Michoacán and Mexico; Pinus; 2.5-4.0 mm
13. ponderosae Hopkins

- Frons with a conspicuous, subacutely elevated carina in both sexes, its lower end forming a distinct tubercle; punctures on declivital striae 2 obsolete except minute on less than basal fourth; declivital sulcus not as deep, broader; Michoacán; Pinus teocote; 3.1-3.7 mm

## 1. Conophthorus monophyllae Hopkins

Conophthorus monophyllae Hopkins, 1915, J. Washington Acad. Sci. 5:433 (Holotype, female; Ventura County, California; U.S. Nat. Mus., 7474)
Diagnosis.- This species is distinguished from edulis Hopkins by the slightly larger size, by the black color, by the much smaller
elytral punctures on disc and declivity, by the host, and by the distribution.

Female. - Length $2.7-3.1 \mathrm{~mm}, 2.3$ times as long as wide; color almost black.

Frons convex, a feeble transverse impression at level of antennal insertion; surface smooth, shining, punctures small,
rather sparse; vestiture short, sparse, inconspicuous.

Pronotum 1.06 times as long as wide; widest near base, sides on basal two-thirds weakly, arcuately converging to moderate constriction, rather broadly rounded in front; anterior margin irregularly armed by about 8-12 variable serrations; summit slightly behind middle; asperities not attaining base even in lateral areas; posterior areas smooth, shining, punctures rather coarse, deep, close. Vestiture of fine, rather short, moderately abundant hair.

Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on slightly more than basal half, then converging slightly and broadly rounded behind; striae not impressed except 1 moderately on posterior two-thirds, punctures rather small, deep, irregularly rather close; interstriae almost smooth, shining, three to four times as wide as striae, punctures slightly smaller than those of striae, closer and slightly confused on basal third, more sparsely uniseriate on posterior half. Declivity steep, convex, shallowly bisulcate; striae 1 impressed, punctures on 1 and 2 smaller than on disc, distinctly impressed; interstriae 1 distinctly elevated, with a few fine punctures, 2 moderately impressed, ascending slightly laterally, lateral convexities slightly higher than suture, their summits at striae 3, punctures on interstriae 3 mesad of summit, very feebly granulate. Strial setae minute, usually abraded; interstrial hair of moderate length except short on 1 on declivity.

Male.- Apparently identical to female.
Distribution.- California to W Utah.
USA: California: Whitney Portal in Inyo Co., Baldwin Lake and San Bernardino N.F. in San Bernardino Co., Ventura Co. Nevada: Baker, Reno. Utah: Iron Co., Sawtooth N.F. in Box Elder Co.

## Host.- Pinus monophylla.

Biology.- Because new attacks occur in the spring and fall and both larvae and adults overwinter in the cones, it is presumed that one or more overlapping generations occur.

Notes. - The above treatment was based on the holotype and on 19 other specimens.

## 2. Conophthorus cembroides Wood

Conophthorus cembroides Wood, 1971, Great Basin Nat. 3I:74 (Holotype, male; Miller Canyon, Huachuca Mits., Arizona; Wood Coll.)
Diagnosis.- This species is distinguished fro medulis Hopkins by the smaller average size of punctures on the pronotum and elytra, by the less strongly impressed interstriae 2 on the declivity, by the slightly impressed frons, by the host, and by the distribution.

Female.- Length 2.2-2.5 mm, 2.3 times as long as wide; color very dark brown, elytra reddish brown.

As in edulis except frons more distinctly impressed, median epistomal tubercle averaging larger, punctures on frons, pronotum, and elytra slightly smaller, discal interstriae 2 more sparsely punctured, declivital interstriae 2 less strongly impressed.

Male.-Similar to female except frontal impression stronger.

Distribution. - Arizona to Hidalgo.
USA: Arizona: Miller Canyon, Huachuca Mts., 8-ViII62, Pinus cembroides, S. L. Wood. MEXICO: Coahuila: 53 km SE Saltillo, 25-V1I-63, A. T. Howden. Hidalgo: Zimapan, I2-VI-60, P. cembroides, F. Islas.

Host. - Pinus cembroides.
Notes. - The above treatment was based on the type series of 17 specimens and on 2 other specimens.

## 3. Conophthorus edulis Hopkins

Conophthorus edulis Hopkins, 1915, J. Washington Acad. Sci. 5:430 (Holotype, female; Las Vegas Hot Springs, New Mexico; U.S. Nat. Mus., 7472)
Diagnosis.- This species is distinguished by the comparatively small size, by the coarse punctures on declivital striae 1 and 2, by the shallow, broad, declivital sulcus, by the absence of granules on declivital interstriae 3, by the host, and by the distribution.

Female.- Length 2.3-3.0 mm, 2.3 times as long as wide; color dark brown, elytra reddish brown.

Frons and pronotum as in monophyllae except punctures on disc not as close, slightly smaller.

Elytra similar to monophyllae except strial punctures on disc larger, interstriae two to
two and one-half times as wide as striae, interstrial punctures almost as large as those of striae, declivital striae 1 and 2 with punctures almost as coarse as those on disc and conspicuously larger than in monophyllae, vestiture slightly longer.

Male.- Similar to female except weak transverse frontal impression stronger, extending from epistoma to upper level of eyes.

Distribution.- Utah and Colorado to Arizona and W Texas.

USA: Arizona: Chiricahua Mts., Kaibab N.F., Santa Catalina Mts., Tucson, Walnut Canyon. Colorado: Buena Vista, Colorado Springs, El Paso, Ft. Garland, Trinidad, Ute Pass. New Mexico: Capulin, High Rolls, Las Vegas Hot Springs. Texas: Big Bend N.P. Utah: Beaver, Iron Co., Junction, Monticello.

Host.- Pinus edulis.
Biology.-Apparently there is one generation per year; only adults overwinter.

Notes.- The above treatment was based on the holotype and on 85 other specimens.

## 4. Conophthorus radiatae Hopkins

Conophthorus radiatae Hopkins, 1915, J. Washington Acad. Sci. 5:432 (Holotype, female; Pacific Grove, California; U.S. Nat. Mus., 7481)
Diagnosis.- This species is distinguished from ponderosac Hopkins by the presence of a row of tubercles on declivital interstriae 1, by the absence of a low, median, subtuberculate elevation on the female epistoma, by the host, and by the distribution.

Female.- Length 3.1-4.1 mm, 2.4 times as long as wide; color black.

Frons as in pondcrosae except punctures much finer, median epistomal, subtuberculate elevation usually absent.

Pronotum as in ponderosae.
Elytra as in ponderosae except declivital interstriae 1 armed by a row of regularly spaced, fine granules, 2 much narrower, about twice as wide as 1 , tubercles on 3 usually slightly larger.

Male.-Similar to female except transverse impression on frons slightly deeper, declivital interstriae 2 more strongly impressed, tubercles on declivital interstriae 3 smaller.

## Distribution.-California.

USA: California: Aptos, Correlitas, and Watsonville in Santa Cruz Co.; Aromas, Asilomar, Pt. Lobos S.P., Pacific Grove, and Prunedale in Monterey Co.; Strawberry Hills in Alameda Co.; Tunitas Creek in San Mateo Co.

Host.- Pinus radiata.
Biology.- Overwintered adults emerge from the broad cone in late February or March and attack two-year-old cones. The female enters the cone near the pedicel on the lower side, bores about 1.5 cm , then constructs a spiral tunnel around the central axis, following which she bores parallel to the axis to near the apex of the cone then tirns and bore on the opposite side of the axis toward the base. The cone turns brown and shrinks to two-thirds of normal size. Eggs ( $1-30$ ) are placed in niches along the tunnel walls and mature in about 40-60 days. Parent adult females may emerge and attack a second cone. There is one generation per year (Schaeffer 1962, 1963, 1964).

Notes.- The above treatment was based on the holotype and on 74 other specimens.

## 5. Conophthorus echinatae Wood

Conophthorus echinatae Wood, 1978, Great Basin Nat. 38:398 (Holotype, female; Winona, Missouri; Wood Coll.)
Diagnosis.- This species is distinguished from coniperda (Schwarz) by the smaller size, by the more slender form, by the more strongly arched elytral declivity, by the coarser pronotal and elytral punctures, and by the weaker transverse frontal impression.

Female.- Length 2.3-2.5 mm, 2.5 times as long as wide; color very dark brown.

Frons as in coniperda except transverse impression between epistoma and upper level of eyes not as deep.

Pronotum as in coniperda except punctures on dise and near base larger, their lateral margins almost never bearing a granule.

Elytra as in coniperda except punctures larger; interstriae two and one-half to three times as wide as striae, declivital sulcus narrower and less strongly impressed, vestiture averaging slightly longer.

Male.-Similar to female except lower half of frons with a distinct, median, subcarinate summit.

Distribution.- Missouri.
USA: Missouri: Winona, VIII-1967, Pinus echinata cone.
Notes.- The above treatment was based on the type series of seven specimens.

## 6. Conophthorus coniperda (Schwarz) Fig. 208

Pityophthorus comiperda Schwarz, 1895. Proc. Ent. Soc: Washington 3:144 Lectotype, male; Marquette, Michigan; U.S. Nat. Mus.; designated by Wood. 1978, Great Basin Nat. 38:384.)
Conophthorus clumicus Hopkins, 1915, J. Washington Acad. Sci. 5:432 (Holotype, female; 13, 122, Tomicus clunicus Fitch, Det. No. 12 Hopk., Collection Fitch; U.S. Nat. Mus.); Wood, 1977, Great Basin Nat. 37:38.4. Synonymy
Conophthorus tacdac Hopkins, 1915, J. Washington Acad. Sci. 5: 431 (Holotype, sex? Ft. Monroe, Va.; U.S. Nat. Mus., 7473.); Wood, 1977, Great Basin Nat. 37:385. Synomymy
Diagnosis.- This species is distinguished by the comparatively small size, by the steep elytral declivity, by the presence of tubercles on declivital interstriae 1 , by the host, and by the distribution.

Female.- Length $2.4-3.0 \mathrm{~mm}, 2.3$ times as long as wide; color almost black.

Frons convex, with a very weak, transverse impression from epistoma to upper level of eyes; surface smooth, shining, punctures rather sparse, moderately coarse; vestiture rather short, sparse, inconspicuous.

Pronotum essentially as in radiatae Hopkins.

Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; essentially as in radiatae except punctures closer, declivity much steeper. Declivital striae 1 and 2 with fine, distinct punctures; interstriae 1 distinctly elevated, armed by a row of fine granules, 2 moderately impressed, about three times as wide as 1 , with numerous impressed points, 3 weakly elevated, armed at summit by a few fine tubercles.

Male.- Similar to female except frons more strongly impressed, punctures evidently coarser, median epistomal tubercle more strongly raised.

Distribution.- Minnesota and Maine to North Carolina.

CANADA: Ontario: Algonquin Park, Angus, Haley Station, Hurkett, Ottawa, Simcoe. Quebec: Lanorare, Quebec. Nova Scotia: Hants Co. USA: Maine: Bangor,

Orono. Massachusetts: Cambridge, Framingham, Marion, Martha's Vineyard, Petersham. Maryland: Ashton. Michigan: Bear Lake, Eagle Harbor, Marquette. Minnesota: Chippewa Falls, Filmore Co., St. Anthony. New Hampshire: Durham, Pike. New Jersey: Clemonton, Greenwood, Lakehurst, Orange Mt. New York: Ithaca, Olcott, Upper Jay, Westbury, West Point. North Carolina: Henderson. Pennsylvania: Cooks Forest, Mt. Alto. Virginia: Culpepper. Monroe, Norfolk. Wisconsin: Clintonville.

Host--Pinus strobus, accidental in other hosts.

Biology.- Specimens were taken from cones of the host.

Notes. - The above treatment was based on the lectotype of coniperda, on the holotypes of clunicus and tacdae, and on 113 other specimens.

## 7. Conophthorus banksianae McPherson

Conophthorus banksianae McPherson, 1970, in McPherson, Stehr, and Wilson, Canadian Ent. 102:1020 (Holotype, male; Fife Lake, Michigan; Michigan State Univ. Coll.)
Diagnosis.- This species is distinguished from resinosae Hopkins by the habit of infesting twig terminals rather than cones and by the host.

Female. - Length $2.4-2.9 \mathrm{~mm}, 2.3$ times as long as wide; color almost black.

Identical to resinosae except elytral hair evidently slightly longer.

Male. - Similar to female except sexes differing as in coniperda.

Distribution.- Ontario to Wisconsin and Michigan.

CANADA: Ontario: Black Sturgeon Lake, Oba, Franz, Sault Ste. Marie. Michigan: Cadillac, Christensen Nursery, Fife Lake, Fish Lake, Grand Traverse Co., Kalkaska Co., Wellston, Wexford Co. Minnesota: Cass Lake, Itasca Co. Wisconsin: Three Lakes.

Host.-Pinus banksiana.
Biology.- This species was originally distinguished entirely on the basis of its habits. Its bores into the pith of its host's twig terminals.

Notes. - The above treatment was based on 14 paratypes and on 27 other specimens. This could be a valid species, but identifying anatomical characters that distinguish it from resinosae have not been found. Of the 41 specimens examined, the largest was 2.9 mm in length. Of 66 specimens of resinosae measured, all but 4 were larger than 3.0 mm . Nevertheless, it is noted that resinosae may
also breed in twigs. The less favorable habitat and abnormal host could account for the size difference in what is here recognized as banksianae. Additional studies are needed to confirm its validity.

## 8. Conophthorus resinosae Hopkins

 Fig. 201Conopthorus resinosae Hopkins, 1915, J. Washington Acad. Sci. 5:431 (Holotype, male; Conoph. resinosae Hopkins, 1 Harring., Conophthorus resinosae; U.S. Nat. Mus., 7483)
Conophthorus virginianae Hopkins, 1915, J. Washington Acad. Sci. 5:4:31 (Holotype, male, not a female as labeled; Huttonsville, West Virginia; U.S. Nat. Mus., 7482); Wood, 1977, Great Basin Nat. 37:385. Synonymy
Diagnosis.- This species is distinguished from coniperda (Schwarz) by the larger average size, by the slightly longer elytral setae, by the more closely spaced interstrial punctures on the disc, and by the smaller punctures on declivital striae 2 .

Female.- Length 2.6-3.4 mm ( 95 percent are larger than 3.0 mm ), 2.3 times as long as wide; color almost black.

As in coniperda except as noted in diagnosis and key.

Male.- Sexual differences as in coniperda.
Distribution.- Minnesota and Wisconsin to New Hampshire and New Jersey.

CANADA: Ontario: Burnt River, Camp Borden, Carp, Chalk River, Dorset, Luden, Midland, Parry Sound, Sault Ste. Marie, Temagami. Quebec: Laniel, Kazubazua, Park Reserve. Nova Scotia: Kentville, USA: Michigan: Keweeno Co., Raco. Minnesota: Cass Lake, ltasco Co. New Hampshire: Effingham. New Jersey: Greenwood Lake. New York: East Hampton, Farmingdate. West Virginia: Huttonsville. Wisconsin: Chippewa Falls.

Host.- Pinus resinosa.
Biology.- This species breeds in the cones of its host, less commonly in twigs.

Notes.- The above treatment was based on the holotypes of resinosae and virginianae and on 166 other specimens.

## 9. Conophthorus mexicanus Wood

Conophthorus mexicanus Wood, 1962, Great Basin Nat. 22:79 (Holotype, male, Necaxa, Puebla, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from ponderosae Hopkins by the larger average size, by the much more strongly impressed elytral declivity, by the smaller
elytral punctures, and by the absence of a median epistomal elevation in the female.

Female.- Length 3.3-4.1 mm, 2.3 times as long as wide; color very dark brown.

Frons largely concealed in only available female (allotype), apparently much more strongly convex than ponderosae, a weak, transverse impression near upper level of eyes; surface smooth, shining, punctures smaller and slightly closer than in ponderosac.

Pronotum about as in ponderosae except lateral crenulations extending to base, margins of punctures on disc each bearing a tubercle, vestiture more abundant.

Elytra 1.3 times as long as wide, 1.7 times as long as pronotum; striae 1 weakly, others not impressed, punctures rather fine, moderately close, in poorly defined rows; interstriae about four times as wide as striae, punctures as large and as close as those of striae, in poorly defined rows, largely confused on basal third. Declivity steep, rather strongly sulcate; striae 1 and 2 almost obsolete, fine punctures obscure; interstriae 1 moderately elevated, usually with tubercles only at extreme base and one just before apex, 2 strongly impressed, three times as wide as 1 , shining, surface not smooth, almost subrugose in some specimens, 3 much higher than 1 , armed at summit by about eight rather coarse tubercles. Vestiture slightly more abundant than in related species.

Male.- Similar to female except declivital tubercles apparently slightly larger.

Distribution.- Puebla.
MEXICO: Puebla: Necaxa, 17-III-60, ex cono, J. Carillo.

Notes. - The above treatment was based on the type series of six specimens and on three other topotypic specimens.

## 10. Conophthorus conicolens Wood

Conophthorus conicolens Wood, 1977, Great Basin Nat. 37:212 (Holotype, female; 8 miles or 13 km W Texmelucan, Puebla, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from ponderosae Hopkins by the convex profile of the frons, by the absence of a median epistomal tubercle or carina in either sex, by the presence of numerous impressed points on the elytral disc, and by the slightly deeper declivital sulcus, with the lateral convexities
very slightly higher than the suture and armed by slightly larger tubercles; margins of punctures on pronotal dise usually less conspicuously subasperate. From mexicanus Wood it is distinguished by the larger elytral punctures and by the much less strongly sulcate declivity, with the lateral convexities only slightly higher than the suture and the tubercles much smaller.

Female.- Length $3.3-3.8 \mathrm{~mm}, 2.2$ times as long as wide; color very dark brown.

Frons and pronotum as in mexicanus, crenulations on pronotal disc distinctly smaller.

Elytra about as in ponderosae except numerous minute, impressed points present on disc, discal punctures slightly larger, slightly confused, declivital sulcus slightly deeper, lateral convexities very slightly higher than suture, and lateral tubercles very slightly larger. Some specimens with surface of disc undulating conspicuously, other smooth.

Male--Similar to female except punctures on frons evidently slightly larger.

Distribution.- Hidalgo and Mexico to Puebla.
MEXICO: Hidalgo: Tulancingo, 24-VI-53, pine cones, S. L. Wood. Mexico: Tlalmonalco, 24 -IX-49, Pinus leiophylla, \#13A, J. P. Perry. Puebla: 13 km W Texmelucan, 13-VI-67, Pinus cones, S. L. Wood.

Host.- Pinus leiophylla.
Biology.- All specimens were taken from cones of the host.

Notes. - The above treatment was based on the type series of 18 specimens.

## 11. Conophthorus apachecae Hopkins

Conophthorus apachecae Hopkins, 1915, J. Washington Acad. Sci. 5:432 (Holotype, male; Chiricahua Mts., Arizona; U.S. Nat. Mus., 7484)
Diagnosis.- This species is distinguished from ponderosae Hopkins by the larger size and by other characters indicated below.

Male.- Length $3.7-3.9 \mathrm{~mm}, 2.3$ times as long as wide; color dark brown.

Frons convex, a weak median summit on lower half, elevation absent.

Pronotum about as in ponderosae except more broadly arched, punctures on disc distinctly larger.

Elytra about as in ponderosae except discal surface slightly irregular (ripples occur on dise corresponding to positions of interstrial punctures; this character is variable), punctures deeper; declivity more strongly impressed, lateral convexities higher than suture, vestiture distinctly longer.

Female.- Similar to male except frontal summit not evident.

Distribution.-Arizona.
USA: Arizona: Chiricahua Mts., 6-VI, Hubbard and Schwarz; Madera Canyon, Santa Rita Mts., 1-VI-78, Pinus cngelmannii, S. L. Wood.

Host.- Pinus engelmannii.
Notes.- The above treatment was based on the holotype, and on six other specimens.

## 12. Conophthorus michoacanae Wood

Conophthorus michoacanae Wood, 1980, Great Basin Nat. 40:354 (Holotype, male; Uruapan, Michoacán, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from apachecae Hopkins by the more slender body, by the less densely punctured, smoother basal half of the elytral disc, by the broader, more gradual elytral declivity, and by other characters cited below.

Male.- Length 3.9-4.2 mm, 2.4 times as long as wide; color very dark reddish brown.

Frons as in apachecae except never with a median crest or tubercle, a weak, transverse impression usually present on upper half of median half of area below upper level of eyes.

Pronotum essentially as in apachecae except slightly more slender.
Elytra resembling apachecae except 1.48 times as long as wide; discal striae with punctures not as close, mostly in rows, interstriae sparsely punctured, punctures only slightly confused on basal fifth, surface smooth, not wrinkled; declivity not as steep, less strongly arched, sulcus deeper and much wider, tubercles on interstriae 3 very small (less strongly arched and more broadly sulcate than in ponderosae); vestiture less abundant, slightly coarser.

Female. - Similar to male in all respects.
Distribution.- Michoacán.
MEXICO: Michoacán: Uruapan, Il-80, Pinus michoacana cones, A. A. del Río Mora.

Notes.- The above treatment was based on the type series of seven specimens.

## 13. Conophthorus ponderosae Hopkins

 Figs. 203-204, 209Conophthorus ponderosae Hopkins, 1915, J. Washington Acad. Sci. 5:4.31 (Holotype, female; Ashland, Oregon; U.S. Nat. Mus., 7479
Conophthorus scopulorum Hopkins, 1915, J. Washington Acad. Sci. 5:431 (Holotype, female; Flagstaff, Arizona; U.S. Nat. Mus., 7480); Wood, 1977, Great Basin Nat. 37:385. Synonymy
Conophthorus contortac Hopkins, 1915, J. Washington Acad. Sci. 5:432 (Holotype, female; Newport Oregon; U.S. Nat. Mus., 7476); Wood, 1977. Great Basin Nat. 37:385. Synonymy
Conophthorus monticolae Hopkins, 1915, J. Washington Acad. Sci. 5:432 (Holotype, female; Priest River, Idaho; U.S. Nat. Mus., 7477); Wood, 1977, Great Basin Nat. 37:385. Synonymy
Conophthorus flexilis Hopkins, 1915, J. Washington Acad. Sci. 5:433 (Holotype, female; Mount Manitou, Colorado U.S. Nat. Mus., 7.475); Wood, 1977, Great Basin Nat. 37:385. Synonymy

5 cm

Fig. 203. lmmature cones of sugar pine attacked by Conophthorus ponderosae. The arrows point to pitch tubes. (After Bedard 1968:3.)

Conophthorus lambertianae Hopkins, 1915, J. Washington Acad. Sci. 5:433 (Holotype, female; Hilt, California; U.S. Nat. Mus., 7478); Wood, 1977, Great Basin Nat. 37:385. Synonymy
Diagnosis.- This species is distinguished by the absence of tubercles on the lower twothirds of declivital interstriae 1 , by the lateral convexities on the declivity being much higher than the suture, by the presence of a low, median, epistomal elevation in the female, by the host, and by the distribution.

Female. - Length 2.5-4.0 mm, 2.4 times as long as wide; color very dark brown, elytra often brown.

Frons transversely convex, longitudinally very weakly concave from epistoma to upper level of eyes; epistoma with a median summit, usually with a conspicuous, low tubercle, often with an obscure, low carina extending dorsad; surface smooth, shining, punctures rather sparse, of moderate size; vestiture inconspicuous.

Pronotum about as long as wide; as in radiatae Hopkins and resinosae Hopkins, disc longer and less strongly arched longitudinally than in mexicanus Wood, discal punctures rather coarse, margins not subasperate.

Elytra 1.6 times as long as wide, 1.7 times as long as pronotum; striae not impressed except 1 near declivity, punctures rather coarse, deep, mostly in rows; interstriae two to three times as wide as striae, smooth, shining, without impressed points, punctures rather sparse, closer and confused toward base. Declivity steep, convex, broadly, shallowly bisulcate; punctures on striae 1 and 2 smaller than on disc, distinct; interstriae 1 moderately elevated, unarmed except a few fine tubercles at base and one near apex, 2 broadly, moderately impressed, three times as wide as 1 , surface shining, with numerous obscure, minute impressed points, 3 distinctly elevated, as high as 1 , tubercles very fine to moderately coarse. Vestiture as in allied spe cies, not abundant.

Male.- Similar to female except frontal tubercle usually absent, transverse impression often more pronounced.

Distribution.- British Columbia and Montana to Michoacán and Mexico.

CANADA: British Columbia: Castlegar, Cobble Hill, Cowichan Lake on Vancouver Island, Crawford Bay, Vancouver. USA: Arizona: Flagstaff, Kaibab N.F., Santa

Catalina Mts. Califomia: Alameda Co., Barton Flat in San Bernardino Co., Big Meadows in Calaveras Co., Cypress Camp in Lassen Co., Dead Horse Summit in Siskiyou Co., Fallen Leaf Lake in El Dorado Co., Hilt, Lake Co., Madera Co., Mariposa Co., Mendocino Co., Modoc Co., Mono Co., Norval Flats, North Fork, Pine Crest, Placerville, Shaver Lake, Plumas Co., Riverside Co., San Diego Co., Santa Barbara Co., Shasta Co., Tehama Co., Tulare Co., Tuohme Co., Yosemite N.P. Colorado: Buena Vista, Boulder, Cheyenne Mts., Crystal Springs, Colorado Springs, Estes Park, Evergreen, Larkspur, La Veta Pass, Longmont, Monument, Mountain Home, Mt. Manitou, Woodland Park. Idaho: Bannock Creek in Boise Co., Bonner Co., Coeur d'Alene. Emida, Idaho City, Mica, Priest Lake. Montana: Lodgegrass. Nebraska: Nenzel, Valentine. Nevada: Baker, Mt. Rose. New Mexico: Cloudcroft, Gila N.F., Lincoln N.F., Silver City. Oregon: Ashland, Colestein, Ferrin G.S., Frederick, Jemmie Creek, Klamath, Mistletoe, Pinehurst. Talent, Tollgate, Waldo. Utah: Beaver, Dutch John, Huntington Canyon, Logan Canyon. Washington: Longmires, Pullman. Wyoming: Centennial, Saratoga, Shell. MEXICO: Durango: El Salto. Mexico: Zoquiapan N.P. Michoacán: Uruapan.

Hosts.- Pinus aristata, P. contorta, $P$. douglasiana, P. durangensis, P. flexilis, P. jeffreyi, P. lambertiana, P. leiophylla, P. monteぇumae, $P$. monticola, $P$. strobiformis, $P$. washoensis.

Biology.- Second-year cones are attacked near their base. The parent adults make a spiral tunnel around the axis of the cone, causing its death, then form an egg tunnel along the axis. The attack apparently begins in May and continues until early July. One female evidently may attack more than one cone. The brood matures in late summer and overwinters in the brood cone.

Notes. - The above treatment was based on the holotypes of ponderosae, scopulorum, contortae, monicolae, flexilis, and lambertianae, and on 784 other specimens. The variability in this material is difficult to interpret. It is entirely possible that two or more sibling species are represented. The material from five-needle pines could be different.

## 14. Conophthorus teocotum Wood

Conophthorus teocotum Wood, 1980, Great Basin Nat. 40:354 (Holotype, male; Uruapan, Michoacán, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from ponderosae Hopkins by the subacutely elevated median carina on the lower half of the frons in both sexes, by the totally obsolete punctures on declivital striae 2 except near base, and by other characters cited below.

Male.- Length 3.1-3.7 mm, 2.3 times as long as wide: color very dark brown.

Frons weakly, transversely impressed as in ponderosae; median line on more than lower half with a conspicuous, subacutely elevated carina, end of carina somewhat tuberculate near epistomal margin.

Pronotum as in ponderosae except asperities averaging smaller, serrations on anterior margin usually reduced, impressed points rather numerous and sharply, distinctly impressed.

Elytra as in ponderosae except punctures on declivital striae 2 obsolete (sometimes resent on less than basal fourth), declivity more broadly, slightly less strongly impressed, tubercles on declivital interstriae 3 slightly larger.

Female. - Similar to male except transverse frontal impression more extensive, slightly more conspicuous, carina slightly shorter.

Distribution.- Michoacán.
MESICO: Michoacán: Uruapan, IIl-80, Pinus teocote cones, A. A. del Río Mora.

Notes.- The above treatment was based on the type series of four specimens.

Genus Pityophthorus Eichhoff

Pityophthorus Eichhoff, 1864, Berliner Ent. Zeitschr. 8:39 (Type-species: Bostrichus lichtensteini Ratzeburg, subsequent designation by Hopkins, 1914, Proc. U.S. Nat. Mus. 48:127)
Trigonogenius Hagedorn, 1912, Deutsche Ent. Zeitschr. 1912:354 (Type-species: Trigonogenius fallax Hagedorn, monobasic); Schedl, 1952, Dusenia 3:347. Synonymy
Hagedornus Lucas, 1920, Cat. Alphabet. Gen. Subgen. Coleopt. 1:683. Replacement name for Trigonogenius; Schedl, 1952, Dusenia 3:347. Synonymy
Myeloburus Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Pub. 25:16 (Type-species: Pityophthorus ramiperda Swaine, original designation); Bright, 1977, Canadian Ent. 109:511. Synonymy
Cnathophorus Schedl, 1935 (nec Kirby, 1837), Rev. de Ent. 5:342 (Type-species: Gnathophorus sparsepilosus Schedl, monobasic); Wood, 1975, Great Basin Nat. 35:391. Synonymy
Pityophthoroides Blackman, 1942, Proc. U.S. Nat. Mus. 92:199 (Type-species: Pityophthoroides pudens Blackman, original designation); Wood, 1977, Great Basin Nat. 37:207. Synonymy
Cladoborus Sawamoto, 1942, Insecta Matsum. 16:165 (Type-species: Cladoborus arakii Sawamoto); Bright, 1977, Canadian Ent. 109:511. Synonymy

Ctenyophthorus Schedl, 1955, Zeit. Angew. Ent. 38:26 (Type-species: Ctenyophthorus glabratulus Schedl, monobasic); Bright, 1977, Canadian Ent. 109:511. Synonymy
Gnathophthorus Wood, 1962, Great Basin Nat. 22:76 (Replacement name for Gnathophorus); Wood, 1975, Great Basin Nat. 35:391. Synomymy
Diagnosis.- This large, diversified genus is distinguished from Araptus Eichhoff by the equally, partly or entirely septate sutures 1 and 2 on the antennal club (sutures sometimes marked only at margins; club small and
sutures straight when septa almost obsolete),
by the reduction or absence of denticles or rugae on the lateral margin of the basal half of the protibia, by the (usually) distinct transverse impression behind the pronotal summit, and by a different assortment of habits.

Description.- Length $0.8-3.2 \mathrm{~mm}$, 2.0-3.4 times as long as wide; color yellowish brown to almost black.

Frons usually sexually dimorphic, male convex to variously impressed, with or without a carina, female convex to concave, commonly ornamented by a tuft of hair. Antennal

Fig. 204. Conophthorus ponderosac: A, adult: B, egg: C, larva; D, pupa. (After Bedard 1968:6.)
scape slender, elongate; funicle 5 -segmented (except 3-5 segmented in costatus Wood), usually about as long as scape; club subcircular to elongate-oval, of moderate size, sutures 1 and 2 straight to rather strongly procurved, partly to entirely, equally septate (when septa strongly reduced, sutures straight and club comparatively small). Pronotum usually elongate, summit usually near middle, usually with a transverse impression behind summit; asperities usually on a definite area on anterior half; lateral margins with a fine, raised line. Scutellum rather large, flat. Elytra usually striate, punctures confused in some species groups; declivity moderately to very steep, convex to strongly bisulcate. Anterior tibiae usually armed by two denticles on apical margin and one subapical denticle on lateral margin. Supplemental rugae on lateral margin sometimes on distal half.

Distribution.- Alaska to Argentina, temperate Europe and Asia, Africa; 213 species occur in North and Central America, about 50 in South America, and about 50 in the remainder of the world.
Biology.- Many of the more primitive species are monogamous; most of the more advanced species are polygynous. A few species breed in the bole of the host; others characteristically infest unthrifty seedlings, shaded out branches, injured tops, slash or broken branches, or the pith of green twigs. A few ubiquitous species may spread into several of these habitats; others are rigidly restricted to one of them. Most species infest the phloem, where the parental tunnels are visible on the inner surface of peeled bark;
others occur only in the central axis of pith in tiny twigs. The parental tunnels of most species are of the radiate type; however, some pith-boring species construct a simple, uniramous tunnel. All species deposit their eggs in niches.

Notes. - The exact limits of Pityophthorus are somewhat obscure. A certain amount of intergradation with Araptus occurs, but I am unable to justify synonymy of them. Conophthocranulus almost certainly should be made a synonym; Conophthorus, Gnatholeptus, and Pityotrichus all contain distinctive species groups, but there is a questicn as to their validity as genera. All four are tentatively given generic status here, but future collecting and study may modify the classification of them.
Note added in press: In 1965, D. E. Bright undertook a revisional study of Pityophthorus in order that his study might become part of this treatise. Our schedule asked that it be completed by 1970. In the early to mid-1970s, I was informed that he had abandoned the study and it was left to me to prepare the revision of this genus. When my study was nearing completion, his study was revived. He examined the entire manuscript of this treatise prior to submission of his manuscript (Bright 1981); I examined his manuscript after my manuscript was submitted for publication. We have attempted to work closely together, but some inconsistencies, differences of opinion in interpretation, and oversights remain. Still, it is felt that both treatments are valuable contributions to our knowledge of this large and very difficult group.

## Key to the Species of Pityophthorus

1. Pronotal asperities confused; punctures on declivital striae 1 and 2 rather small or obsolete; male frons usually with a definite longitudinal or transverse carina; on coniferous and broadleaf hosts

- Asperities on anterior slope of pronotum between anterior margin and summit arranged into two or more definite, concentric rows, adjacent asperities within a row usually basally contiguous (if doubtful, then declivital striae 1 and 2 with punctures rather strongly impressed); male frons either without a definite carina or with a transverse carina; sutural apex of elytra never acuminate (see also couplet 136); rarely on coniferous hosts

| 2(1). | Elytral apex obtusely rounded at suture (see also accuminatus, sparsepilosus, tropical); male frons either without a carina, with a longitudinal carina, or with a poorly developed transverse carina (in which case interstrial punctures absent on disc); when declivity sulcate, punctures on striae 1 and 2 usually obsolete if on coniferous hosts (except nocturnus) |
| :---: | :---: |

Elytral apex moderately to strongly acuminate, when acumination poorly
developed, punctures on elytral disc confused (except sparsepilosus) and
male frons with a conspicuous transverse carina at upper level of eyes ............. 136

3(2). $\quad$| Tropical species in nonconiferous hosts; female frons unmodified, without a |
| :--- |
| tuft of hair, except a small tuft in pudicus and inceptis, male frons never |
| with a carina of any kind (a subcarinate crest in elegans); declivital sculpture |
| usually conservative, with punctures on striae 2 distinct ....................................... 4 |

- Temperate and tropical species, mostly in conifers or Quercus; female frons modified from that of male, almost always with a tuft of long setae, male frons either with or without a carina, almost always conspicuously different from female (except ramiperda group, lecontci); declivital sculpture variable16
4(3). Elytral declivity convex, interstriae 3 never armed by granules ..... 5
- Elytral declivity rather shallowly to strongly bisulcate, interstriae 2 impressed and without punctures or granules, 3 armed by small granules in male and usually also in female10
5(4). Pronotal asperities low, costiform, length of some equal to more than one- fourth width of pronotum; pronotal disc strongly reticulate, punctures fine, sparse; elytra with numerous impressed points, strial punctures small, rather shallow; Costa Rica; woody vine; 1.1-1.2 mm 1. costatus Wood- Pronotal asperities normal, short, not costiform; pronotal disc rather weaklyreticulate, coarsely punctured; elytra with points inconspicuous or absent,strial punctures rather coarse and deep; larger species6
6(5). Smaller; declivital striae 1 and 2 not impressed, punctures smaller; female frons ornamented by a conspicuous tuft of long hair ..... 7
- Larger; declivital striae 1 and 2 weakly to moderately impressed, punctures rather coarse; female frons with vestiture sparse, inconspicuous ..... 8

7(6). Punctures on pronotum and elytra smaller; male frons less strongly convex; Jalisco; Sambucus; 1.3-1.5 mm

- Punctures on pronotum and elytra coarser; male frons more strongly convex; Michoacán to Jalisco; 1.5-1.6 mm (generic placement doubtful) 3. exquisitus (Blackman)

8(6). Pronotum rugose-reticulate, rugae on posterior half coarser; elytral surface wrinkled, punctures slightly confused; Chiapas; Quercus; 1.7-2.0 mm
4. melanurus Wood

- Pronotal disc almost smooth and with etched, impressed points or reticulate, rugae smaller or absent, less numerous; elytral surface smooth or nearly so
9(8). Pronotum smooth, shining; strial punctures coarser, deeper, interstriae on disc smooth, about twice as wide as striae; declivital interstriae 2 with setae; Hidalgo to Veracruz; Alnus; 2.0-2.4 mm

5. alni Blackman

- Pronotum reticulate, dull; strial punctures very small, shallow, interstriae with numerous impressed lines, three or more times as wide as striae; Oaxaca; Alnus; 1.5-1.7 mm

6. alnicolens Wood

10(4). Head and pronotum smooth, shining; frons, at least in male, weakly to very
strongly, transversely impressed ..... 11

- Head and pronotum reticulate; frons convex in both sexes ..... 15
11(10). Male frons very strongly, transversely impressed just below upper level of eyes; declivity shallowly sulcate, interstriae 3 rather weakly elevated ..... 12
- Male frons shallowly impressed; declivity very strongly bisulcate, interstriae 3 strongly elevated, rather coarsely tuberculate (except without tubercles in female degener)

12(11). Very slender, 3.1 times as long as wide; declivity more broadly flattened on lower two-thirds, sulcus rather wide; male frons rather strongly, evenly, transversely impressed from epistoma to upper level of eyes; color light brown; Guatemala; 1.3 mm
7. elegans Schedl

Slender, 2.6-2.8 times as long as wide; declivity more convex, sulcus narrow; male frons more irregularly impressed; color dark brown
13(12). Larger; pronotal punctures averaging larger; punctures on female declivital interstriae 3 at least weakly granulate; declivital setae slightly longer, more slender; Panama; 1.8-2.0 mm
8. timidulus Wood

- Smaller; pronotal punctures averaging smaller; punctures on female declivital interstriae 3 not granulate: declivital setae shorter, stouter; Costa Rica; $1.5-1.7 \mathrm{~mm}$ 9. mendosus Wood

14(11). Median line reticulate to transversely etched from upper level of eyes to vertex; male frons somewhat irregular, lateral areas at least partly rugose, female frons finely punctured, finely pubescent; female declivital interstriae 1 and 3 unarmed; Panama; $1.7-2.0 \mathrm{~mm}$ (see also 11. punctiger Schedl, "Mexico," 1.7 mm )

- Median line smooth, brightly shining from upper level of eyes to vertex; frons not sexually dimorphic, surface coarsely punctured, neither rugose nor of irregular sclupture; declivital interstriae 1 and 3 armed by tubercles in both sexes; Veracruz to Costa Rica; woody vine; $1.7-1.9 \mathrm{~mm}$

12. amiculus Wood

15(10). Frontal punctures fine; declivity with striae strongly impressed, surface of sulcus ascending from striae 1 to 2; Costa Rica to Panama; woody vine; $1.4-1.6 \mathrm{~mm}$ 13. dissolutus Wood

- Frontal punctures coarse; declivital sulcus broad, deep, its surface on lower half not ascending from striae 1 to 2; Puebla woody vine; $1.5-1.7 \mathrm{~mm}$

14. explicitus Wood

16(3). Male frons unarmed or with a median carina between epistoma and upper level of eyes, those species having male carina poorly developed or absent with interstrial punctures on at least alternate discal interstriae or with all discal punctures confused; species with male frontal carina poorly developed, usually with declivital sulcus shallowly impressed, its margins weakly tuberculate and punctures on striae 2 visible (except margins spectacularly elevated in cristatus)
Male frons either with a transverse carina, a weak median carina above upper level of eyes, or, when absent, strial punctures in definite rows and discal interstriae devoid of punctures (except medialis)

17(16). Male frons either with or without a median carina; female frons simple or pubescent, with or without a median carina; declivital interstriae 2 little if any wider than on disc, either not impressed or narrowly impressed only at or near striae 1 , interstriae 1 and 3 usually devoid of granules, very minute granules present in two species; strial punctures very small, usually in rows, interstrial punctures sparse to obsolete; elytra usually with rather abundant, short setae of about equal length arising from strial and interstrial punctures; mostly smaller species

- Male frons with or without a median carina; female frons simple or pubescent, never with a median carina; declivital interstriae 2 much wider than on dise, shallowly to rather strongly impressed, 1 and 3 usually with distinct tubercles; discal punctures confused or in rows, interstrial punctures absent and striae in definite rows only when male frons with a conspicuous median carina; mostly larger species with strial setae obsolete
18(17). Anterior margin of pronotum armed by 14 serrations; long hair on female frons extending to vertex; Durango; Pinus cooperi; 1.3-1.5 mm

15. thomasi Bright

- Anterior margin of pronotum armed by 2-8 serrations; hair on female frons never extending more than slightly above upper level of eyes
19(18). Anterior margin of pronotum armed by six to eight denticles; female frons never ornamented by a tuft of long hair; male frons either with or without a median carina
- Anterior margin or pronotum usually armed by two or four denticles (up to eight if female frons pubescent); female frons either with or without a tuft of long hair, when female hair present then male carina short, occupying about half distance from epistoma to upper level of eyes

20(19). Frons with a sharply elevated median carina in both sexes, carina extending
from epistomal margin at least to upper level of eyes

- Either frons without a definite median carina in either sex or else male with short carina
21(20). Elytral disc with punctures conspicuously smaller toward declivity, those on basal fourth strongly confused, interstrial punctures moderately abundant; British Columbia and Alberta to California and New Mexico; Pinus; 1.4-2.0 mm 16. digestus (LeConte)
- Strial punctures on disc in rows to base, not conspicuously reduced in size posteriorly, interstrial punctures sparse to absent; pronotum at least partly reticulate on posterior areas; Arizona and Jalisco to Veracruz; Pinus; 1.3-1.6 mm
22(20). Male carina absent; elytral disc with punctures confused; pronotal disc usually partly reticulate; Minnesota and Kansas to Nova Scotia and Virginia; Pinus, Abies; $1.2-1.5 \mathrm{~mm}$

18. puberulus (LeConte)

- Elytral punctures in distinct rows, interstrial punctures sparse or absent

23(22). Strial punctures on disc coarse, interstriae only slightly wider than striae, only slightly smaller on declivity; female frontal vestiture short, male frons with small, subdentate, median carina on lower half; Veracruz; Pinus; $1.5-1.6 \mathrm{~mm}$

- Strial punctures smaller, interstriae at least twice as wide as striae, punctureson declivity much smaller; frons variable24

24(23). Male carina usually absent or poorly defined; female body less than 2.6 times as long as wide; strial punctures larger, interstriae about twice as wide as striae; basal area of elytra not wrinkled; elytra smooth, brightly shining, declivity more strongly convex, sulcus not indicated (punctures of declivital striae 2 and 3 replaced in one species by minute granules similar to those of interstriae)

- Male carina always present; female body more slender, 2.8 or more times as long as wide; strial punctures very small, interstriae about four or more times (only two times in minus) as wide as interstriae, discal surface often subreticulate; female frons punctured, with or without long hair; base of elytra usually wrinkled

$$
26
$$

25(24). Female frons broadly convex, rather coarsely punctured, vestiture short, inconspicuous; declivital interstriae 2 indistinctly if at all impressed, punctures on 3 not granulate; California to New Mexico; Pinus edulis, P. monophylla, P. quadrifolia; $1.4-1.8 \mathrm{~mm}$ 20. punctifrons Bright Female frons flat to plano-concave, impunctate and brightly shining, with a
confused row of punctures on margins, punctures bearing a marginal row of
long setae; median side of declivital interstriae 2 weakly impressed, on 3
minute granules replacing punctures; California and Baja California to Utah
and Durango; Pinus edulis, P. monophylla; 1.5-1.8 mm ................................................................................................................................... Blackman
26(24). Pronotal and elytral surfaces often obscurely articulate; discal interstriae impunctate; odd-numbered declivital interstriae with a few rather long setae; male frons reticulate, a definite median carina on lower half, its highest point at epistoma, female frons with rather sparse, moderately long, almost uniformly distributed setae to upper level of eyes
Pronotal and elytral surfaces smooth; at least some punctures on oddnumbered discal interstriae; declivital setae short; male frons never reticulate
27(26). Elytral declivity with interstriae 1 and 3 entirely devoid of granules; elytral setae minute, interstrial setae not longer than those of striae; Arizona; 1.8 mm 22. minus Bright

- Declivital interstriae 1 and 3 each armed by a row of very fine granules; odd-numbered declivital interstriae with a few setae two to four times as long as those of striae; Arizona and New Mexico to Durango; Pinus; 1.6-1.9 mm (see also subopacus Blackman)

23. segnis Blackman

28(26). Declivity narrowly, rather deeply sulcate, lateral convexities much higher than suture; female frons never with long hair; Nuevo León; Pinus culminicolae; $1.5-1.9 \mathrm{~mm}$
24. culminicolae Bright

- Declivity feebly to weakly sulcate, suture as high as lateral convexities; female frons pubescent or not
29(28). Larger; interstrial punctures on disc sparse, but more abundant; pronotal dise without granules behind summit; female frons plano-concave, rather coarsely punctured, ornamented by more abundant, longer hair; British Columbia and Alberta to California and Colorado; Abies lasiocarpa, Pinus; $1.6-1.8 \mathrm{~mm}$

25. absonus Blackman

Smaller; interstrial punctures on disc minute, sparse, pronotal disc with several small, distinct granules behind summit; female frons plano-convex to moderately convex, finely to moderately punctured, glabrous to ornamented by a sparse marginal fringe of moderately long hair; Alaska and Nova Scotia to California and West Virginia; Picea, less common in Abies, Pinus; 1.1-1.6 mm
26. opaculus LeConte

30(19). Pronotum usually reticulate; male frontal carina extending from epistoma to
well above eyes, female vestiture short; punctures on basal third of elytral disc moderately confused; Hidalgo to Guatemala; Pinus; 1.3-1.5 mm
27. pellitus Schedl

Pronotal disc smooth or partly reticulate; male carina short, not extending
above eyes (an obscure extension in woodi) ......................................................... 31
31(30). Female frons broadly, shallowly concave; male carina attaining upper le...............................................................................................................................

- Female frons convex, more uniformly punctured; male carina not attaining $\begin{aligned} & \text { upper level of eyes ............................................................................................. } 33\end{aligned}$

32(31). Larger; female frons shallowly concave to well above upper level of eyes, lateral and dorsal margins ornamented by long hair; declivital interstriae 3 armed by a row of fine granules; Utah and Arizona to California; Pinus aristata, P. flexilis; $1.7-1.9 \mathrm{~mm}$
28. mormon Bright

- Smaller; female frontal impression not extending above upper level of eyes, vestiture mostly short, sparse; declivital interstriae 3 unarmed; New Mexico; Pinus edulis; $1.1-1.3 \mathrm{~mm}$

29. woodi Bright

33(31). Elytral punctures very fine, usually entirely obsolete on declivity; pronotum often partly reticulate or subreticulate; male carina fine, low, extending to upper level of eyes; female frons broadly flattened, coarsely punctured, and ornamented by moderately abundant, long hair; California; Pinus lambertiana, P. ponderosa; 1.3-1.5 mm ............................................ 30. dolus Wood

- Elytral punctures rather fine, usually visible on declivity; pronotum surface between punctures smooth; female frons flattened on a smaller area, punctures on lower half fine, with or without long hair
34(33). Declivity not as steep, sulcus wider, interstriae 1 and 3 armed by minute granules; strial punctures distinctly larger; female frons more broadly flattened, bearing a rather sparse marginal fringe of long hair; Nuevo León; Pinus strobiformis; $1.6-1.7 \mathrm{~mm}$

31. clivus Bright

- Declivity steep, sulcus feeble to moderate, narrow, unarmed; strial punctures smaller; female frons less extensively flattened, with or without sparse pubescence; California and South Dakota to Durango; Pinus; 1.3-1.7 mm .... 32. deletus LeConte

35(17). Male and female frons similar, at least weakly convex, rather coarsely punctured, with or without a weak median carina on lower half; female frons never ornamented by long hair; antennal club with sutures aseptate; elytral punctures rather fine, in rows; declivity shallowly bisulcate; pith borers in twigs of Pinus36

- Male frons usually convex, often with a conspicuous median carina, female frons either bearing a tuft of long hair, or, when hair absent, much more densely, more finely punctured than in male and never with a median carina43

36(35). Frons more strongly convex, carina absent; antennal club subcircular in outline, suture 2 at or beyond middle of club; interstriae 8 never convexly elevated37

- Frons less strongly convex, with a weak, median carina on lower half; suture 2 usually attaining middle of club, antennal club distinctly longer than wide (antennal characters obscure in some males); interstriae 8 at base of declivity distinctly convex, weakly elevated

37(36). Interstrial setae very short, not longer than those of striae; declivital interstriae without granules, striae 1 strongly impressed, lateral area evenly convex from striae 1; California; Pinus radiata; $1.5-1.9 \mathrm{~mm} . . .33$. trepidus Bright

- Interstrial setae four or more times as long as those of striae; declivital interstriae 2 more distinctly impressed, 3 with fine granules 38
38(37). Elytral declivity more nearly convex, very feebly sulcate; declivital interstriae 2 with a row of setiferous punctures or minute granules; frontal punctures much smaller, interspaces mostly twice as wide as a puncture; California to Colorado; Pinus monophylla, P. edulis; 1.8-2.2 mm

34. keeni (Blackman)

- Elytral declivity weakly sulcate, interstriae 2 without punctures, granules, or setae except at base; frontal punctures very coarse, interspaces mostly narrower than punctures; E Nevada and Wyoming to Arizona and New Mexico; Pinus flexilis, P. strobiformis; 1.9-2.3 mm ............ 35. pinguus (Blackman)
39(36). Declivital sulcus very shallow, narrow, interstriae 2 with a row of punctures and/or minute granules, striae 1 and 2 distinctly punctured; South Carolina; 2.4 mm

36. separatus Bright

- Declivital sulcus more strongly impressed, interstriae 2 never with punctures or granules, punctures on striae 1 and 2 strongly reduced or absent
40(39). Declivity with convexity on interstriae 8 ending before junction with 3,3 not convex; margins of punctures on pronotal disc bearing small granules; elytral punctures moderately fine to very fine; frons less strongly convex below upper level of eyes, punctures finer; British Columbia and California to South Dakota and Colorado; Pinus; 1.9-2.9 mm

37. boycei Swaine

- Punctures on pronotal disc not armed by fine granules; elytral punctures averaging larger; frons very slightly more strongly convex
41(40). Declivity with convexity on interstriae 8 ending before junction with 3,3 weakly if at all convex; elytral punctures rather coarse; declivital interstriae 2 twice as wide as 1; Arizona and New Mexico; Pinus ponderosa; 2.1-3.0 mm

38. amplus (Blackman)

- Declivital interstriae 8 convex to junction with 3,3 weakly elevated; elytral punctures rather fine; declivital interstriae 2 one and one-half times as wide as 1 42
42(41). Smaller; pronotal dise smooth, shining, punctures larger; lateral convexities of declivity ascending from striae 1, much higher than suture; Wisconsin and Quebec to New York; Pinus; $1.9-2.6 \mathrm{~mm}$

39. ramiperda Swaine

- Larger; pronotal disc reticulate, punctures finer; lateral convexities of declivity ascending from striae 2, very slightly higher than suture; Nuevo León to Puebla; Pinus; $3.0-3.5 \mathrm{~mm}$
43(35). Declivital striae 1 and 2 with punctures small to moderately large, distinctly impressed, with discal punctures coarse, deep, confused; male frons usually without a carina or carina not clearly formed44
- Punctures on declivital striae 1 and 2 obsolete, or, if present (diglyphus
group from Mexico and Central America), discal striae in rows and
interstriae impunctate; male frons with or without a carina
53

44(43). $\begin{aligned} & \text { Pronotum 0.8-1.0 times as long as wide, sumnit at or posterior to middle; } \\ & \text { anterior margin weakly serrate; declivity more broadly, more shallowly } \\ & \text { sulcate, interstriae } 1 \text { and } 3 \text { never granulate; larger, stouter species .................... } 45\end{aligned}$
Pronotum 1.1-1.2 times as long as wide, summit at or slightly in front of
middle, anterior margin moderately to coarsely serrate; declivity broadly to
rather narrowly sulcate, impression shallow to moderately deep, interstriae 1
and 3 either with or without granules ................................................................... 49

45(44). Declivital interstriae 2 three times as wide as 1 ; male frons with a strong transverse impression but without any indication of a carina in or below this impression; elytral vestiture fine, very long, rather abundant, arising from both strial and interstrial punctures; Arizona and New Mexico to Durango; Pinus ponderosa; 2.3-3.2 mm 41. comosus Blackman

- Declivital interstriae 2 less than one and one-half times as wide as 1 ; male
frons with a short median carina dividing impressed area; elytral vestiture
shorter

46(45). Male frons indistinctly impressed; declivity more strongly impressed, discal punctures less abundant; Durango to Mexico; Arceuthobium globosum; 1.8-2.0 mm .............................................................................. 42. arceuthobii Wood

- Much larger species, on Pinus; male frons rather strongly impressed; declivital sulcus shallow, discal punctures more abundant 47

> 47(46). Male frons with transverse impression rather weak, not at all concave; punctures on discs of pronotum and elytra moderately fine, spaces between punctures equal to one to three diameters of a puncture, vestiture much shorter, less abundant; Mexico to Veracruz; Pinus; $2.3-3.6 \mathrm{~mm}$............ 43 . aztecus Bright

- Upper two-thirds of area below upper level of eyes on male frons rather deeply, concavely impressed; punctures on discs of pronotum and elytra coarse, spaces between punctures equal to diameter of a puncture or less, vestiture distinctly longer, coarser, more abundant48

48(47). Male frons moderately, less strongly, rather narrowly concave, median carina evident only at lower margin, rather weak; female frons irregularly, more narrowly flattened, more finely punctured, vestiture shorter, finer; pronotal disc obscurely reticulate, less closely punctured, interspaces as wide as a puncture; declivital interstriae 1 and 2 with closely spaced, short setae (spacing equal to one-third length of a seta); Chiapas; Pinus; 2.1-2.8 mm ......
44. dispar Bright

- Male frons broadly, very strongly biconcave, median carina conspicuous; female frons more broadly flattened, more coarsely punctured, vestiture coarser, more conspicuous; pronotal disc smooth, shining, much more closely punctured, interspaces about one-fourth as wide as a puncture; setae on declivital interstriae 1 and 2 more widely spaced, spaced by more than onehalf length of a seta; Nevada and Arizona to Honduras; Pinus; 2.2-2.8 mm ... 45. schwerdtfergeri (SchedI)

49(44). Declivital interstriae 1 and 3 punctured, with no indication of granules; female frons with vestiture short to moderately long, less abundant, never extending above upper level of eyes

- $\quad \begin{aligned} & \text { Declivital interstriae } 1 \text { and } 3 \text { each with a row of granules; female frons with } \\ & \text { abundant long hair, pubescent area extending well above eyes, male frons } \\ & \text { with a median callus at upper level of eyes ............................................................ } 52\end{aligned}$

50(49). Declivital interstriae 2 narrow, as wide as 1 ; male frons evenly convex, female frons ornamented by long hair; Minnesota and Nova Scotia to Texas, Florida, and Cuba; Pinus; $1.5-2.2 \mathrm{~mm}$
46. pulicarius (Zimmermann)
Declivital interstriae 2 twice as wide as 1; male frons transversely impressed, longitudinally concave in median area between epistoma and upper level of eyes, female frons weakly convex, vestiture rather sparse, a few moderately long setae ..... 51
51(50). Declivital interstriae 2 coarsely, closely punctured, 1 and 3 with obscure rounded granules, 1 higher than 3 ; declivital sulcus broad, very shallow; Arizona and New Mexico to Chiapas; Pinus; $1.5-2.6 \mathrm{~mm}$ 47. solus Blackman Guatemala; Pinus; 1.9-2.5 mm 48. aciculatus Bright
52(49). Elytral declivity shallowly impressed, interstriae 2 twice as wide as 1 , tu-bercles on 1 and 3 minute; body slender, 2.7 times as long as wide;California; Pinus; $1.9-2.7 \mathrm{~mm}$49. carmeli Swaine
Elytral declivity rather strongly impressed, interstriae 2 little if any widerthan 1 , tubercles on 1 and 3 rather coarse; body stout, 2.4 times as lorg aswide; Nayarit to Honduras; Pinus; 1.9-2.4 mm50. scabridus Schedl
53(43). Mostly smaller (1.4-2.4 mm), more slender species; strial punctures in rows to base or, if moderately confused, then male frons without a carina, male carina strongly developed when discal interstriae impunctate ..... 54

- Larger (2.1-2.9 mm), stouter species; punctures on elytral disc coarse, deep, very strongly confused; male frons armed by a short, strongly elevated carina; elytral declivity rather strongly sulcate ..... 10254(53).54(53). Lateral margins of punctures on pronotal disc armed by a granule (exceptscalptor, fuscus); declivity more gradual, occupying 35-40 percent of elytrallength, broadly, shallowly sulcate, striae 2 distinctly, regularly, minutelypunctured to apex, interstriae 2 at least twice as wide as 1 (except scalptor),granules on 1 and 3 subequal in size, minute; pronotal disc never reticulate(except scalptor); male frontal carina weakly elevated, strongest onepistomal margin; declivital interstriae 8 sometimes feebly convex55
- Lateral margins of punctures on pronotal disc unarmed (except elatinus); de- clivity steeper, usually occupying less than 30 percent of elytral length, de- clivity variable, punctures on striae 2 obsolete through most of its course (except orarius, sierraensis); interstriae 8 never elevated ..... 62
55(54). Elytral surface at least weakly reticulate; declivital interstriae 2 one and one-half times as wide as 1 ; punctures on pronotal disc without granules on their lateral margins; female frons very shallowly concave on central half, ornamented by yellow hair ..... 56
Elytral surface smooth, often with irregular lines; declivital interstriae 2 twoto three times as wide as 1 ; margins of punctures on pronotal disc armed bygranules; female frons weakly convex to narrowly plano-concave (exceptconcave in scalptus), epistoma with a weak elevation or fine tubercle57
56(55). Female frons almost flat to shallowly concave on small area not extendingabove eyes, vestiture more uniformly distributed, little if any longer on mar-gins, longest setae equal to less than one-third distance between eyes; elytralvestiture more consistently present; declivital tubercles usually slightlylarger; California; Pinus ponderosa; $2.0-2.6 \mathrm{~mm}$51. leechi Wood
- Female frons rather strongly, broadly concave, impression extending wellabove eyes, vestiture sparse and short in central area, dense and very long onmargins, longest setae equal to at least two-third distance between eyes; ely-tral vestiture often less abundant to absent; declivital tubercles usually small-er; British Columbia to California; Pinusp; 2.2-2.7 mm

57(55). Female frons concave, concavity rather sparsely punctured, margin ornamented by long hair; discal interstriae 2 and 4 impunctate; declivital interstriae 2 less strongly impressed; British Columbia to Colorado; Pinus ponderosa; 2.3-2.8 mm

- Female frons convex; all discal interstriae with at least some punctures (absent on 2 and 4 on posterior two-thirds in nitidus); declivital interstriae 2 more strongly impressed
58(57). Discal interstriae 2 and 4 impunctate on posterior two-thirds; female frons feebly to moderately convex, with or without long hair, margins near eyes rounded; male frons with carina fine, low, usually long; punctures on declivital striae 1 and 2 usually conspicuous; Alaska and Newfoundland to Oregon, Colorado, and Nova Scotia; Picea, Pinus; $1.6-2.4 \mathrm{~mm}$

54. nitidus Swaine

- Discal interstriae 2 and 4 punctured at least on posterior third; female frons either plano-convex and with long hair or convex and with very minute hair; male carina much more strongly developed
59(58). Discal punctures on pronotum minute or entirely replaced by granules; discal punctures on elytra minute, interstriae regularly punctured; female frons convex, margins near eyes rounded, vestiture minute
- Discal puntures on pronotum moderately coarse, usually larger than granules; discal punctures on elytra moderately fine, interstrial punctures irregular; female frons at least partly plano-concave, margins abruptly subangulate near eyes, lateral and dorsal margins ornamented by long hair
60(59). Pronotal and elytral discs with punctures minute, interstriae at least six times as wide as striae; declivital sulcus slightly deeper; Colorado; Pinus contorta; 2.0-2.3 mm

55. indigus Wood

- Pronotal and elytral punctures moderately coarse, interstriae not more than twice as wide as striae; declivital sulcus not as deep; British Columbia to Montana; Pinus contorta; $2.0-2.2 \mathrm{~mm}$
61(59). Lower half of male frons more shallowly impressed, smoother, more finely punctured; longitudinal crest of carina concave, poorly developed on upper half; female frons dull, more finely punctured, spaces between punctures equal to one to three diameters of a puncture, hair usually longer; declivital striae 1 and 2 finely, distinctly punctured; Alberta to Idaho; Larix lyallii; $2.3-2.7 \mathrm{~mm}$....................................................................... 57. alpinensis G. Hopping
- Lower half of male frons more strongly impressed, more coarsely, subgranulately punctured, longitudinal crest of carina convex, upper half more strongly elevated; female frons more nearly shining, more coarsely punctured, spaces between punctures equal to less than diameter of a puncture, marginal hair usually slightly shorter; declivital striae 1 and 2 obsolete or very minutely punctured; British Columbia and Alberta to California and Utah; Pinus; 2.1-2.7 mm ................................................................. 58. toralis Wood
62(54). Male declivity convex or normally sulcate, with minute to moderately coarse granules on interstriae 3 and usually on 1 ; female frons convex, flat, or shallowly concave, variously ornamented by setae; stouter species63

Male declivity entirely devoid of granules, interstriae 3 with middle area
rather prominently elevated to almost spinelike process and weakly to very
strongly protruding or displaced toward suture; female frons variously, con-
cavely impressed and ornamented by spongy areas, carinae, or patches of
setae; rather small, slender species from NE North America (see also
carinulatus) .................................................................................................... 96

| 63(62). | Declivital striae 2 regularly punctured to near apex, these punctures coarse to very minute, but clearly indicated on surface (see also brevis) $\qquad$ 64 |
| :---: | :---: |
| - | Punctures on declivital striae 2 obsolete except near base (an occasional puncture sometimes present, but not in a row, except variable in brevis) $\qquad$ 80 |
| 64(63). | Declivity moderately to strongly, rather narrowly sulcate, striae 2 finely to rather coarsely punctured, striae 1 and 2 almost parallel, tubercles on interstriae 3 usually more numerous and regularly placed to level of junction with 8,1 partly or entirely without tubercles, S USA to Honduras |
| - | Declivital sulcus moderately impressed to almost absent, rather wide when present, punctures on striae 2 minute but distinct on surface, interstriae 2 much wider near middle of declivity, tubercles on interstriae 3 usually less numerous, often obsolete on lower fourth, 1 always with fine tubercles. $\qquad$ 74 |
| $65(64)$. | Lower third of declivital interstriae 3 convex, rather weakly, narrowly elevated, elevation continued to junction with 8 and along apical part of 8 $\qquad$ 66 |
| - | Lower third of declivital interstriae 3 not elevated or convex ........................... 71 |
| $66(65)$. | Male frons convex, carina short to long, if long more strongly elevated on its middle third; female frons minutely punctured, vestiture moderately abundant, very fine, slightly longer on margins, longest setae equal to less than half distance between eyes; declivital setae rather short $\qquad$ 67 |
| - | Male frons conspicuously, transversely impressed below upper level of eyes, carina strongly developed (except absent in ineditus), subdentate on its lower half; female frontal vestiture distinctly more abundant and longer ............ 68 |
| 67(66). | Male frontal carina extending about half distance from epistoma to upper level of eyes; female frons distinctly convex, punctures slightly larger; pronotal disc smooth; declivital interstriae 2 ascending laterally; declivital setae moderately long; Veracruz; Pinus; $1.5-1.6 \mathrm{~mm}$ (see also 60 . sapineus Bright) $\qquad$ 59. litos Bright |
| - | Male frontal carina much longer, extending to upper level of eyes; female frons more broadly flattened, punctures minute; pronotal disc reticulate; declivital interstriae 2 flat; declivital setae short; Oaxaca to Guatemala; Pinus; $1.7-2.1 \mathrm{~mm}$ $\qquad$ 61. glabratulus (Schedl) |
| 68(66). | Male frontal carina absent; declivital striae 1 impressed, interstriae 2 ascending, little if any wider than 1 , tubercles on 3 rather coarse; Veracruz to Oaxaca; Pinus; 1.7-2.0 mm $\qquad$ 62. ineditus Bright |
| - | Male frontal carina well developed; declivital striae 1 and 2 equally impressed, interstriae 2 flat, twice as wide as 1 , tubercles on 3 fine $\qquad$ 69 |
| 69(68). | Female frons with median sixth glabrous from epistoma to vertex, this area usually impunctate; declivital setae short, rarely longer than diameter of an interstriae; punctures on pronotal dise averaging larger; Michoacán to Veracruz and Oaxaca; Pinus; $1.9-2.3 \mathrm{~mm}$ $\qquad$ 63. leiophyllae Blackman |
| - | Female frons with punctures and setae on mesal sixth; either some declivital setae three or more times longer than width of an interstriae or else pronotal disc subreticulate; punctures on pronotal disc averaging smaller .. |
| 70(69). | Elytral declivity with setae on interstriae 3 three or more times as long as width of an interstriae; pronotal disc smooth; male frons more strongly impressed, carina more strongly elevated, occupying only lower half of impressed area; Guatemala; Pinus pseudostrobus; 2.3-2.3 mm |

| - | Elytral declivity with setae short, none longer than width of an interstriae; pronotal disc usually reticulate; male frons weakly impressed, a weak median carina occupying most of length of impressed area; Durango; Pinus; $1.7-1.8 \mathrm{~mm}$ $\qquad$ 65. vespertinus Bright |
| :---: | :---: |
| 71(65). | Elytral surface subreticulate; declivity more gradual, setae on interstriae 3 very long; Mexico; Abies religiosa; 2.3-2.7 mm $\qquad$ 66. rudis Blackman |
|  | Elytral surface smooth; declivity steep, setae shorter ........................................ 72 |
| 72(71). | Male carina acutely elevated; declivity more narrowly, less strongly sulcate, its lateral convexities more broadly rounded, granules fine, punctures on striae 2 very fine; British Columbia and South Dakota to California and W Texas; Pinus; $1.7-2.1 \mathrm{~mm}$ $\qquad$ 67. venustus Blackman |
| - | Male frontal carina low, long, thick to obsolete; declivity very steep, strongly sulcate, its lateral convexities rather abruptly rounded and armed on interstriae 3 by a row of rather large tubercles, punctures on striae 2 moderately fine to rather coarse (not clearly visible in male laticeps) |

73(72). Female frons more distinctly convex, punctures slightly coarser, not as close, vestiture of moderate length; declivity with suture more strongly arched, sulcus deeper, lateral convexities higher, particularly on lower third, margins armed by about six tubercles; Arizona to Oaxaca; Pinus; 1.9-2.6 mm
68. durus Blackman

- Female frons weakly plano-convex, punctures smaller, closer, more abundant, vestiture much longer; declivity less strongly arched, very weakly in male, margins armed in female by two to four small tubercles, in male areas laterad from interstriae 3 much more massive, causing lower third to appear more broadly flattened; Оахаса; Pinus; 2.1-2.8 mm

69. laticeps Bright

74(64). Interstriae 2 at base of declivity armed by two or three fine granules, usually a few additional punctures present; female frons not entirely flat, with pubescence sparse, short, inconspicuous; male frontal carina not as high 75

- Interstriae 2 at base of declivity never with tubercles, rarely with punctures; female frons mostly flat, with a conspicuous brush of long hair (glabrous in tumidus); male frontal carina higher, usually subdentate 78

75(74). Declivity shallowly, broadly sulcate, granules on interstriae 1 and 3 very fine; punctures on posterior half of pronotum much closer, surface often subrugose in lateral areas; color black; British Columbia; Pseudotsuga; 2.0-2.2 mm
70. orarius Bright

- Declivity rather strongly sulcate, granules on interstriae 3 rather coarse; punctures on posterior half of pronotum less numerous, surface regular; color brown 76
76(75). Declivital sulcus rather shallow, suture as high as lateral convexities; elytral and pronotal punctures rather fine; British Columbia; Picea; 1.8-2.0 mm ......

71. recens Bright

- Declivital sulcus rather deep, lateral convexities conspicuously higher than suture; elytral and pronotal punctures rather coarse; Veracruz to Oaxaca; Pinus; $1.4-1.7 \mathrm{~mm}$ (see also 72. amoenus, Guatemala, 2.0 mm )

73. declivisetosus Bright

78(74). Declivital interstriae feebly impressed at striae 1 ; female frons rather coarsely, closely punctured, subglabrous, male frons with a strong, subdentate carina; pronotal disc very coarsely, very closely punctured; California; 2.1-2.2 mm
74. tumidus Blackman

- $\quad$| Declivity more distinctly impressed, pronotal disc less closely, more finely |
| :--- |
| punctured; female frons pubescent ....................................................................... 79 |

79(78). Male frontal carina poorly developed, visible only near epistoma; female frons more extensively flattened, about one-third of area above eyes, very closely, rather coarsely punctured, vestiture more abundant, slightly longer; surface of elytral dise more regular, punctures mostly finer, more regularly in strial rows; British Columbia and California to Wyoming; Pinus, Abies; $2.0-2.5 \mathrm{~mm}$
75. sierraensis Bright

- Male frontal carina strongly, acutely elevated, subdentate in many specimens; female frons flattened on a semicircular area, less than one-sixth of it above upper level of eyes, vestiture much finer, less abundant, slightly shorter; surface of elytral disc often irregular, punctures averaging slightly larger, interstrial punctures more commonly present; Alberta and California to New Mexico; Pinus; 1.9-2.2 mm

76. aquilus Blackman

80(63). Male and female frons similar, moderately convex, coarsely, deeply punctured, a conspicuous carina from epistoma to upper level of eyes; declivity very broadly, rather shallowly sulcate, upper third of striae 2 strongly divergent from suture and armed by a row of very fine granules similar to those on interstriae 1 and 3; Arizona and New Mexico to Chihuahua; Pinus cembroides, P. edulis; 1.7-2.2 mm ............................................... 77. lecontei Bright

- Male and female frons strikingly dissimilar; declivital striae 2 never armed by granules except for one to three at extreme base present in some species
81(80). Male frontal carina absent or weakly developed, its summit obtusely
rounded; interstriae 2 at base of declivity armed by about one to three
tubercles, several punctures sometimes also present ............................................ 82
- Male frontal carina strongly, acutely elevated; interstriae 2 at base of declivity unarmed and usually devoid of punctures
82(81). Discal interstriae 2 impunctate (all interstriae impunctate in some specimens), strial punctures in definite rows to base, strial setae obsolete; declivital sulcus deep, rather narrow; Mexico
- Discal interstriae 2 punctured, strial punctures on disc usually confused toward base, strial setae present to base (abraded in some older specimens); declivital sulcus shallow, broad (except moderately deep in blandus, brevis)85

83(82). Female frons plano-convex; vestiture sparse, short; posterior areas of pronotum obscurely subreticulate; elytral declivity with no tubercles lateral to those on interstriae 3; length of setae on lateral areas of declivity three or more times greater than width of an interstriae; Colorado to Durango; Pinus; $1.6-2.1 \mathrm{~mm}$
78. brevis Blackman

- Female frons more broadly flattened, more coarsely punctured, vestiture abundant, very long; posterior areas of pronotum almost smooth, impressed points sometimes visible; elytral declivity with two or three tubercles lateral to those on interstriae 3, vestiture about half as long
84(83). Female frons densely, finely punctured, vestiture much more abundant; lower declivity lateral to interstriae 3 more fully rounded; Oregon to California; Pinus ponderosa; 2.2 mm

79. electus Blackman

- Female frons less closely, more coarsely punctured, vestiture less abundant; lower declivity in lateral areas more narrowly rounded; California to Colorado and Arizona; Pinus edulis, P. monophylla; 1.8-2.0 mm

| 85(82). | Declivity very strongly, broadly excavated from base to apex, lateral margins strongly, subacutely elevated throughout, its crest serrate on basal third; <br> Arizona to Michoacán and Veracruz; Pinus; 1.8-2.2 mm ......... 81. cristatus Wood |
| :---: | :---: |
| - | clivity rather s |

86(85). Pronotal disc reticulate; male frontal carina strongly elevated, subdentate on lower half; declivital sulcus rather shallow, lateral margins armed by small tubercles; Alaska to Arizona and New Mexico; Picea engelmannii, P. pungens; 2.1-2.4 mm
82. carinulatus Swaine

- Pronotal disc smooth, often with impressed points; male carina absent or very weakly elevated; declivital sulcus more deeply impressed, tubercles usually larger87

87(86). Declivital sulcus moderately to rather strongly impressed, lateral convexities strongly elevated, summit of male more broadly rounded, interstriae 1 with granules throughout its length; female frontal pubescence separated from margin of eye by space equal to diameter of about two facets

- Declivital sulcus strongly to very strongly impressed, lateral convexities in male strongly, subacutely elevated, interstriae 1 unarmed by granules on basal two-thirds; female frontal pubescence usually extending to margin of eye or less than diameter of one facet from it89

88(87). Female frontal vestiture very little longer on margins, male frons more strongly convex; declivital sulcus narrower, ascending laterally from striae 1 , sulcus slightly deeper, areas laterad from interstriae 3 more fully rounded; Chiapas to Guatemala; Pinus hartwegii; 1.9-2.2 mm
83. blandulus Schedl

- Female frontal vestiture much longer on margins, male frons less strongly convex; declivital sulcus wider; interstriae 2 flatter, ascending from its lateral third, area laterad from interstriae 3 more narrowly rounded; Veracruz; Pinus; 1.7-2.1 mm

84. ciliatus Blackman

89(87). Smaller; punctures (when present) on interstriae 2 at base of declivity not tuberculate; lateral convexities on declivity less strongly elevated, summit armed by fine tubercles; anterior margin of pronotum rather narrowly rounded; California; Pinus attenuata; 1.7 mm
85. californicus Bright

- Larger; interstriae 2 at base of declivity with a row of $2-5$ small tubercles; lateral convexities on declivity strongly elevated, summit armed by several moderately coarse tubercles; anterior margin of pronotum rather broadly rounded
$90(89)$. Female frons minutely punctured, interspaces two to five diameters of a puncture; male frons with a broad callus or low carina; lateral margins of declivital sulcus less strongly elevated
- Female frons finely punctured, interspaces averaging about one diameter of a puncture in width, male frons with a definite carina92

91(90). Pronotal disc dull, reticulate; female frons plano-convex, vestiture on margins less abundant, not as long; male declivity deeply impressed, sulcus not as narrow; male frons with a median callus or carina near and above upper level of eyes; color almost black; Arizona; Abies concolor; 2.0-2.4 mm
86. apachae Bright

- Pronotal dise smooth, shining; female frons feebly, transversely impressed near middle, vestiture on margins more abundant, much longer; male declivity much deeper, narrower; male frons with a low, obtuse carina almost from epistoma to upper level of eyes; color dark brown; Mexico; Abies religiosa; 2.0-2.5 mm (see also 88. micans Bright)

87. blackmani Bright

92(90). Carina on male frons short, at upper level of eyes, female frontal setae more abundant, longer, longest setae equal to almost one-third distance between eyes; declivity not as steep, middle third of lateral margins more abruptly elevated; Durango to Guatemala and El Salvador; Pinus; 2.2-2.4 mm
89. nigricans Blandford

- Carina on male frons long, extending from epistoma to upper level of eyes; female frontal setae less abundant, shorter, longest setae equal to less than one-fourth distance between eyes; declivity steeper, suture and lateral margins more evenly arched; Oaxaca to Veracruz; Pinus; $1.6-2.5 \mathrm{~mm}$

90. lepidus Bright

93(81). Female frons very broadly plano-concave, margins abrupt, pubescence reddish yellow, longest setae equal in length to distance between eyes; male frontal carina almost uniformly elevated, rather low; declivity strongly sulcate, lateral convexities very much higher than suture94

- Female frons plano-convex, setae shorter; male carina strongly elevated, subdentate; declivity less strongly sulcate, suture about as high as lateral convexities 95
94(93). Punctures on pronotal disc with fine granules; declivital sulcus more strongly impressed, interstriae 1 and 3 without definite granules; Michoacán to Tlaxcala; Abies religiosa; 1.8-2.5 mm

91. elatinus Wood

- Punctures on pronotal disc without granules; declivital sulcus less strongly impressed, interstriae 1 and 3 with small tubercles; Nuevo León; Abies, Pseudotsuga; 1.9-2.7 mm

92. speculum Bright

95(94). Lateral convexities of declivity armed on interstriae 3 by a single row of tubercles, rarely one or two supplemental tubercles in lateral areas, vestiture sparse, normal; male frons weakly convex, carina subdentate; female frons almost flat, vestiture less abundant in central area; Alberta and Nova Scotia to North Carolina; Picea; 1.9-2.2 mm 93. dentifrons Blackman

- Lateral convexities of declivity armed by numerous small, rounded granules, pubescence much more abundant, forming a conspicuous tuft in female; male frons impressed to upper level of eyes; female frons more strongly convex, vestiture more abundant; California; Pinus radiata; 1.8-2.0 mm

94. setosus Blackman

96(62). Male declivity normally bisulcate, lateral summits not noticeably displaced toward suture (except concacus); female frons highly variable 97

- Male declivity with lateral summits displaced mesally and reaching interstriae 1 ; female frons variable ..... 99
$97(96)$. Female frons biconcave to upper level of eyes, with elevated median line subcarinate, concavities glabrous, brightly shining, lateral and dorsal margins of frons ornamented by a fringe of moderately long hair; Ontario to New York and Maine; Picea, Pinus; 1.7-2.0 mm 95. biovalis Blackman
- Female frons with spongy areas, median line impressed or sulcate ....................... 98

98(97). Median half or more of female frons concave to upper level of eyes, lateral areas spongy and protuberant or not; male declivity with lateral convexities almost reaching striae 1; British Columbia, Ontario, and Wisconsin to New Brunswick and Maine; Pinus, Picea; 1.8-2.0 (see also 96. cavatus and 97. hesperius) 97. concavus Blackman

- Female frons usually more narrowly sulcate, lateral spongy areas variable, median half of spongy areas sometimes protuberant; if so, then sulcus usually carried on protuberance or occasionally replaced by a median elevation; Ontario and Minnesota to New Brunswick and Pennsylvania; Pinus, Picea; $1.6-1.9 \mathrm{~mm}$

98. briscoei Blackman
\(\left.\begin{array}{ll}99(96). Female frons slightly convex, broadly spongy, median line feebly elevated, <br>

with or without a median epistomal tubercle; Michigan and Nova Scotia to\end{array}\right\}\)| North Carolina; Picea, Abies, Pinus; 1.6-1.8 mm ..........99. balsameus Blackman |
| :--- |

100(99). Median crest on female frons obtuse, rather low, lateral concavities shallow;
Ontario and Nova Scotia to North Carolina; Abies, Picea, Pinus; 2.0-2.1
$\mathrm{mm} . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . ~ 100 . ~ a n g u s t u s ~ B l a c k m a n ~$

- Median crest on female frons strongly, acutely elevated, forming a thin, rather high partition, lateral concavities deep, rather extensive101

101(100). Median crest on female frons very thin, its summit glabrous; New Brunswick to New York; Picea; 1.8-1.9 mm ............................ 101. carinatus carinatus Bright

- Median crest on female frons thicker, its crest pubescent; British Columbia to Alberta; Pinus contorta; 1.9-2.1 mm

102. carinatus monticolae Bright

102(53). Male declivital sulcus very narrow on upper half, lateral convexities appearing to arise from interstriae 2, a blunt, hornlike process arising just above middle on lateral convexity and projecting toward suture, often crossing striae 1 (specimens from southern part of range may lack this horn); female frons minutely pilose to above eyes (North Carolina specimens somtimes with longer, less dense setae); Manitoba and Nova Scotia to Kentucky and North Carolina; Picea, Pinus, Abies; 2.1-2.5 mm .............. 103. cariniceps LeConte

- Declivity more broadly sulcate, lateral convexities arising from lateral half of interstriae 2, lateral convexities in male armed by small denticles directed caudad; female frons with long to moderately long setae
103(102). Male carina consisting of a coarse, blunt tubercle slightly below upper level of eyes and receding to slightly above eyes; female frons convex except flattened on median half of lower half, pubescent area extending slightly above eyes; British Columbia and Montana to California and New Mexico; Pinus; 2.2-2.9 mm 104. confinis LeConte
- Male carina acute, occupying part or all of median line on lower half, frons transversely impressed at upper level of eyes (except in montezumae); female frons flattened and pubescent to well above upper level of eyes

104(103). Male frons not impressed, its surface reticulate; pronotum reticulate; vestiture on female frons distinctly longer; interstriae 1 on declivity armed by a row of fine tubercles; Chiapas; Pinus montezuma; 2.3-2.5 mm
105. montezumae Bright

- Male frons distinctly impressed below upper level of eyes, its surface shining; pronotum smooth, shining, usually with impressed points; vestiture on female frons distinctly shorter; declivital interstriae l usually unarmed

105(104). Antennal club larger, subcircular in outline, its width equal to length of scape; male frontal carina very short, subdentate, occupying less than middle third of distance between epistoma and upper level of eyes; male declivital interstriae 3 terminating abruptly at middle of declivity, its summit strongly elevated but short, armed by about three or four granules, granules on lower area confused, not in line with those on elevated area; female frons less extensively flattened above eyes, its surface more finely, more sparsely punc tured; longest setae on elytral disc not longer than width of an interstriae, those on declivity about twice as long; Utah to Tlaxcala; Pinus edulis, P. cembroides, etc.; $1.8-2.5 \mathrm{~mm}$
106. schwarzi Blackman

- Antennal club smaller, elongate, scape 1.2 times as long as width of club; male frontal carina occupying about two-thirds of median line between epistoma and upper level of eyes; crest of elevation on male declivital interstriae 3 longer, declining posteriorly more gradually, armed by five to ten granules, most of those on lower half of declivity in line with those on crest; longest setae on disc equal to one to three times width of an interstriae, those on declivity little if any longer; Wyoming to Oaxaca and Veracruz; Pinus; 2.5-2.9 mm

107. crassus Blackman

106(16). Elytral declivity convex to moderately impressed (if moderately impressed then host Quercus), striae 2 distinctly, regularly punctured to near apex; male frons either without a carina or with a weak median carina; in either coniferous or nonconiferous hosts

- Declivity moderately to strongly sulcate, striae 2 impunctate or at most with a few minute, irregularly placed punctures near apex; male frons either without a carina or with a transverse carina at upper level of eyes; in coniferous hosts
107(106). Male frons convex, without any indication of a carina between epistoma and upper level of eyes; discal interstriae with confused impressed points appearing as minute punctures; tropical species in nonconiferous hosts ..... 108
- Male frons with a short, poorly developed median carina at epistomal mar- gin (occasionally somewhat longer, but absent in anthricinus); declivity convex to narrowly, shallowly impressed; in coniferous hosts ..... 115
108(107). Pronotum less than 1.05 times as long as wide; lateral granules on elytral de- clivity minute to obsolete, declivity convex or very shallowly sulcate; in hosts not Quercus ..... 109
- Pronotum 1.1-1.3 times as long as wide; lateral granules on elytral declivity minute to rather coarse, sulcus feebly to strongly impressed; in Quercus ..... 110
109(108). Declivity convex, lateral granules obsolete; pronotal disc with numerous im- pressed points; declivital interstriae 1 and 3 each with a row of about 12 setae; Costa Rica; tree branch; $1.6-1.7 \mathrm{~mm}$ 108. laetus Wood
- Declivity rather narrowly, moderately sulcate, lateral granules small, distinct; pronotal dise reticulate; declivital interstriae 1 and 3 each with a row of about six setae; Costa Rica; woody vine; 1.2-1.4 mm 109. lenis Wood
110(108). Punctures on declivital striae 1 and 2 rather coarse, only slightly smaller than on dise; smaller species ..... 111
- Punctures on declivital striae 1 and 2 minute, usually less than one-fourth as large as those on dise ..... 112

111(110). Declivity convex, interstriae 1 distinctly, weakly elevated, 1 and 3 with a few fine granules; pronotal disc subreticulate, punctures moderately coarse; female frons with marginal hair rather long, setae in central area uniformly short; Honduras; Quercus; $1.6-1.7 \mathrm{~mm}$ 110. parilis Wood

- Declivity steep, rather strongly sulcate, suture unarmed, lateral convexities armed by two pairs of denticles on upper half; pronotal disc shining, minute and rather fine punctures intermixed; female frons with central pubescence only slightly shorter than on margins; Costa Rica and Panama; Quercus; $1.8-2.1 \mathrm{~mm} . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . ~ 111 . ~ s c i t u l u s ~ W o o d ~$
112(110). Declivity not impressed, granules on 1 and 3 very small; sutures 1 and 2 on antennal club rather strongly procurved; male frons almost flat, shining, more sparsely, more finely punctured; female frons flattened on smaller area, vestiture less abundant; Costa Rica; Quercus; 1.6-1.8 mm
- Declivity sulcate, granules on 1 and 3 larger; male frons strongly convex and granulate-punctate above; female frons flattened on a larger area, vestiture rather abundant; sutures on antennal club either straight or moderately procurved

113(112). All discal interstriae with a row of punctures subequal to those of striae in addition to confused, minute impressed points; declivity less strongly impressed, granules on lateral areas slightly smaller; female frons more extensively flattened, with more abundant hair; antennal club with sutures 1 and 2 moderately procurved; Costa Rica; Quercus; 1.9-2.4 mm
113. medialis Wood

- Discal interstriae impunctate, minute, confused, impressed points present; declivity more strongly impressed, granules on interstriae 1 and 3 larger; sutures 1 and 2 on antennal club straight

114(113). Female frons more distinctly convex, finely punctured only on median half below upper level of eyes, smooth median area on lower third distinctly carinate, vestiture confined to median half below upper level of eyes; Guatemala; Quercus; $1.8-2.7 \mathrm{~mm}$............................. 114. guatemalensis Blandford

- Female frons broadly flattened, more coarsely punctured, carina absent, vestiture confined to median two-thirds, at least one-third of setae above upper level of eyes; Durango to Michoacán and Oaxaca; Quercus; 1.9-2.4 mm

115. quercinus Wood

115(107). Elytral dise reticulate; declivital striae 1 and 2 rather coarsely punctured, punctures almost as coarse as on disc, interstriae 2 weakly impressed; vestiture on female frons less abundant, shorter

- Elytral dise shining; punctures on declivital striae 1 and 2 very small, sulcus narrow but distinctly impressed; female frontal vestiture more abundant, longer

116(115). Declivity more evenly convex, sulcus at striae 1 almost obsolete; male frons more distinctly convex on lower half, carina obtuse to obsolete, female frontal vestiture sparse; Durango and Nuevo León to Michoacán and Veracruz; Pinus; $1.6-2.0 \mathrm{~mm}$ (to 2.2 mm in var. elimatus) (intergrades with segnis) 116. subopacus Blackman

- Declivity more distinctly sulcate; male frons more nearly flattened on lower half, carina short, usually acutely elevated, female frontal vestiture more abundant; Durango to Michoacán and Mexico; Pinus; 1.5-2.0 mm

117. impexus Bright

117(115). Female frons flat, male frons without a carina; strial punctures very fine, interstriae more irregular, with impressed lines; color almost black; Nuevo León; Abies; $1.6-1.7 \mathrm{~mm}$ 118. anthracinus Bright

- Female frons slightly, transversely impressed on middle third, uniformly, rather closely, finely punctured over entire surface; male frontal carina moderately long, setae very short, inconspicuous; color brown; Hidalgo to Guatemala; Pinus; $1.7-1.9 \mathrm{~mm}$

119. nocturnus Blandford

118(106). Interstriae 2 at base of declivity smooth, without punctures or tubercles (occasionally present in some cascoensis); male with or without a carina, transverse carina when present usually rather poorly developed or with a dorsal extension

- Interstriae 2 at base of declivity with a row of punctures and/or tubercles, in several species these tubercles form a row slightly mesad of lateral crest and supplement those of interstriae 3 ; male frons with transverse carina strongly, rather sharply elevated, never with a dorsal extension on median line

119(118). Male frons convex, coarsely punctured, without a carina; female frons flat, coarsely, closely punctured, setae in central area minute, those on margins very long; pronotal punctures small, elongate; Guatemala; Abies guatemalensis; 1.9-2.2 mm
120. mesembria Bright

- Male frons either with a carina or variously impressed, female frons finely or more sparsely punctured; north temperate species

120(119). Male frons convex, not transversely impressed on lower half, a weak median carina usually present on lower half; elytral disc feebly reticulate, almost never with impressed points, interstriae 2-5 usually sparsely punctured; declivital interstriae 1 with a row of regularly placed setae; female frons variable, pubescent or not but marginal setae never longer than those in central area; Northwest Territories to Newfoundland and New York; Picea; 1.6-2.2 mm
121. cascoensis Blackman

- Male frons transversely impressed on lower half, never with a median carina on lower half; elytral dise smooth, shining, often with impressed points (reticulate in some tuberculatus); declivital interstriae 1 glabrous or with only one or two setae and discal interstriae impunctate, impunctate only when setae in central area of female frons subequal in abundance and length with those on margins

121(120). Declivital interstriae 1 glabrous, rarely with one or two setae; discal interstriae impunctate; female frons variable, glabrous to densely pubescent, setae uniformly distributed; male transverse carina at upper level of eyes present or absent, never with a dorsal extension, interstrial setae on female declivity usually minute

- Declivital interstriae 1 with a row of regularly spaced setae; discal interstriae frequently sparsely punctured; female frons with central area subglabrous and impunctate to sparsely punctured; male carina usually with a dorsal extension

122(121). Female frons glabrous to rather densely pubescent, lateral margins rounded, longest setae equal to up to one-fourth distance between eyes; male transverse carina at upper level of eyes obscure or absent; British Columbia and Wyoming to Newfoundland and West Virginia; Picea; 1.4-2.0 mm
122. intextus Blackman

Female frons rather densely pubescent, margins rather abruptly subangulate,
longest setae on dorsal margin equal in length to at least half distance be-
tween eyes; male transverse carina usually subacutely elevated (not elevated
in some species) ..................................................................................................... 123
123(122). Female frontal pubescence rather dense, mostly of uniform length; male carina usually well defined, surface more coarsely punctured; Utah to Wyoming and Colorado; Picea pungens; $1.6-2.3 \mathrm{~mm}$......... 123. ornatus Blackman
Female frontal pubescence less dense in central area, very long on margins, particularly above, longest setae almost equal in length to distance between eyes; male frons less distinctly carinate at upper level of eyes

124. infulatus Blackman

- Pronotal disc smooth, shining, discal punctures each with a feeble granule on margin; female frontal punctures apparently more numerous; California; Pinus sabiniana; 1.9 mm

125. novellus Blackman

125(121). Female frons with central area near lateral and upper margins bearing a few rather coarse setiferous punctures, row of marginal setae rather sparse; elytra never reticulate, punctures averaging slightly larger; NE British Columbia and New Brunswick to E Texas and North Carolina; Pinus; 1.6-2.2 mm
126. pulchellus Eichhoff

- Female frons almost never with punctures or setae in central area, marginal row of setae rather dense and longer; elytra frequently reticulate, punctures averaging smaller; Alaska and Alberta to California and Coahuila; Pinus; $1.7-2.4 \mathrm{~mm}$

127. tuberculatus Eichhoff

126(118). Elytral disc rather strongly, uniformly reticulate; male frontal carina less strongly elevated, female frons smooth, with moderately coarse, rather widely spaced punctures; male declivital sulcus similar to female, punctures at base of interstriae 2 weakly if at all tuberculate; British Columbia and Montana to California and Colorado; Abies, Pseudotsuga, Picea, Pinus; 1.6-2.0 mm
128. pseudotsugae Swaine

- Elytral dise shining; male carina more strongly elevated (except montivagus, furnissi), female frons either much more finely punctured or punctures much more abundant; male declivital sulcus much stronger than female and punctures at base on interstriae conspicuously tuberculate and continued on inner margin of lateral crest to middle of declivity in addition to tubercles on interstriae 3

127(126). Smaller; male frons without a median carina, transverse carina only moderately elevated; declivital sulcus narrow, tubercles on lateral convexities very small

- Larger; lower half of male frons with a median carina, transverse carina much more strongly elevated; declivital sulcus deeper, wider, tubercles on lateral convexities larger
128(127). Female frons with short hair uniformly distributed; declivity rather narrowly sulcate in both sexes, without an additional constriction near middle; declivital vestiture much more abundant; Mexico; Pinus hartwegii; 1.9-2.3 mm

129. furnissi Bright

- Male elytral declivity at middle with sulcus very narrow, lateral margins devoid of tubercles; female frons rather strongly biconcavely impressed, lateral margin on lower half of each concavity with a small tuft of very short hair; Oaxaca; Pinus; 1.9-2.3 mm

130. montivagus Bright

129(127). Hair on femate frons uniformly short, longest setae equal to less than onesixth distance between eyes; declivital sulcus not as deep; declivital vestiture much more abundant; Nuevo León; Pinus strobiformis; 1.9-2.1 mm 131. brevicomatus Bright

- Hair on female frons long, much longer on margins; declivital sulcus deeper; declivital hair less abundant

130(129). Female frons with punctures very small, less abundant, vestiture on vertex of
greater length than distance to epistomal margin .......................................... 132

- Female frons with punctures moderately coarse, rather abundant, vestiture much shorter

132(131). Elytral setae on disc and declivity short, interstrial setae little if any longer than those of striae, particularly in female; punctures on discal interstriae and striae smaller; declivity less strongly sulcate in male, in female striae 2 with punctures absent; SW Wyoming, SE Utah, Colorado, and New Mexico; Picea engelmannii, $P$. pungens; $1.9-2.4 \mathrm{~mm}$ 132. occidentalis Blackman

- $\quad$ Strial setae on disc usually absent, interstrial setae on and near declivity at least four times as long as those of striae; punctures on discal interstriae larger; pronotal disc more nearly glabrous; male declivity much more strongly sulcate, female striae 2 with minute punctures through much of its course (except in cortezi)

133(132). Smaller; declivity steeper, sulcus not as deep or as wide; Alaska and California to Utah and South Dakota; Picea, Pinus; 1.8-2.6 mm
133. nitidulus (Mannerheim)

- Larger; declivity not as steep, sulcus much deeper, wider 134

134(133). Smaller; declivity not as deep, wider on basal half; strial setae on disc usually obsolete; longest female frontal setae equal in length to less than half distance between eyes; Nuevo León; Pinus culminicola; $2.5-2.7 \mathrm{~mm}$ 134. viminalis Bright

- Larger; declivity deeper, narrower on basal half; strial setae on disc usually conspicuous, extending to base; longest setae on female frons equal in length to two-thirds distance between eyes; Mexico to Puebla; Pinus hartwegii; $2.4-3.2 \mathrm{~mm}$ 135. cortezi Bright

135(130). Posterolateral areas of pronotum reticulate, rather coarsely punctured; female frons rather closely punctured, punctures spaced by about one diameter of a puncture, vestiture finer, slightly shorter, less abundant; Mexico and Puebla to Oaxaca; Abies religiosa; $2.0-2.4 \mathrm{~mm}$ 136. abiegnus Wood

- Posterolateral areas of pronotum smooth, finely punctured; female frons densely punctured, interspaces between punctures less than half as wide as a puncture, vestiture moderately coarse, slightly longer, more abundant; Arizona to New Mexico; Pinus strobiformis; $1.9-2.8 \mathrm{~mm}$

136(2). Tropical and temperate species in coniferous hosts; pronotum smooth, shining (partly, weakly reticulate in perotei); declivity not as steep, punctures on striae 2 smaller to obsolete, interstriae 2 usually less strongly, more broadly impressed

- Tropical species in nonconiferous hosts; pronotum strongly reticulate (except sparsepilosus); declivital striae 2 with punctures strongly impressed, usually larger; declivity steeper, interstriae 2 usually more strongly impressed (pronotal asperities in some species either confused or concentric; although some species always have confused asperities, all are referred to the division where allied species are placed; see also couplet 1)

137(136). Male frons weakly convex to slightly impressed on lower half, never with a transverse carina at upper level of eyes; strial punctures varying from straight, regular rows to slightly confused; declivital striae 2 usually more strongly punctured; interstriae 2 at base of declivity usually without punctures or tubercles

- Male frons with a conspicuous transverse carina at upper level of eyes, area below carina moderately impressed (never finely, densely punctured or with fine, abundant vestiture); strial punctures varying from strongly confused to definite, regular rows; punctures on declivital striae 2 fine to obsolete; punctures or tubercles usually present on interstriae 2 at base of declivity

138(137). Male frons punctured similar to female (very fine and dense except in perotei) and ornamented by moderately long, rather abundant, fine hair (less abundant and shorter than in female), surface (except discretus) finely, densely punctured (as in females of many species), sometimes irregularly to rather strongly impressed; lateral margin of pronotum never grooved

- Male frons with vestiture short, sparse, inconspicuous, punctures rather coarse, larger and much less abundant than in female; lateral margin of pronotum sometimes longitudinally grooved

139(138). Male frons moderately convex, rather coarsely punctured, female frons plano-convex; pronotal disc either reticulate or else with granules replacing punctures; elytral apex strongly acuminate

- Male frons almost flat to irregularly impressed, surface densely, finely impressed; pronotum never reticulate; elytral apex subacuminate

140(139). Pronotal disc rather strongly reticulate, punctures moderately coarse, their margins not tuberculate; frons more coarsely punctured, vestiture shorter, longest setae in female equal in length to about one-fifth distance between eyes, shorter in male; declivity slightly steeper, sulcus slightly wider and deeper; Durango to Jalisco and Puebla; Pinus; 1.6-2.2 mm

- Pronotal disc smooth and shining, small, rounded tubercles replace most punctures; frons more finely punctured, longest setae in female equal in length to half distance between eyes, shorter in male; declivity more gradual, sulcus narrower, not as deep; Veracruz; Pinus; 1.5-1.9 mm

139. perotei Blackman

141(139). Frons coarsely, closely, deeply punctured in both sexes, frontal vestiture less abundant, male frons shallowly impressed on lower half, a conspicuous median callus on vertex, female frons plano-convex; Michoacán to Mexico; Pinus; 2.4-2.5 mm
140. chalcoensis Hopkins

- Frons very finely, densely punctured in both sexes, vestiture more abundant, $\begin{aligned} & \text { male without a median ele....................................................... } 142\end{aligned}$

142(141). Male and female frons plano-convex, surface sometimes granular in female; female frons with a few marginal setae longer than those in central area; Oaxaca to NW Nicaragua; Pinus; 2.1-2.6 mm
141. miniatus Bright

- Male frons subconcavely impressed; female frons flat to feebly impressed, punctures fine, dense, close, pubescence much more abundant, numerous marginal setae conspicuously longer than those in central area; Arizona to Durango; Pinus; 2.3-3.2 mm

142. ingens Blackman

143(138). Lateral margin of pronotum longitudinally grooved (occasionally obscure in
males); female frons feebly to moderately concave on more than central
two-thirds, marginal vestiture rather abundant, long

- Lateral margin of pronotum normal, marked by a finely elevated line; fe
male frons flat to moderately concave, vestiture variable, often sparse, short,
or absent ..... 145

144(143). Larger; female frons rather strongly concave, rather coarsely, closely punctured; male frons transversely impressed to moderately concave, closely, rather coarsely punctured; declivital interstriae 2 minutely reticulate; Pennsylvania and E Texas to Florida, Durango and Jalisco to N Nicaragua; Pinus; $1.9-2.4 \mathrm{~mm}$
143. confusus Blandford

- Smaller; female frons plano-concave, smooth, shining, punctures minute, rather abundant; male frons rather weakly, transversely impressed, often with a weak transverse carina at upper level of eyes, coarsely, less closely punctured; declivital interstriae 2 smooth, brightly shining; Virginia and West Virginia to E Texas and Florida, Durango and Veracruz to British Honduras; Pinus; 1.3-1.7 mm

144. annectens LeConte

145(143). Female frons more extensively plano-convex and pubescent to well above eyes, punctures smaller, vestiture finer and much longer; interstriae 2 at base of declivity often without punctures or tubercles; from Mexico and Central America

- Female frons usually more strongly convex, short pubescent not extending above upper level of eyes (some variants of murrayanae with frons flat and densely pubescent to vertex); interstriae 2 at base of declivity with a few punctures or tubercles; from America north of Mexico

146(145). Female frons more broadly, more densely pubescent, flattened area separated from eye by distance equal to diameter of two facets, punctures much finer, closer; body 2.9 times as long as wide; declivity steeper, apex less strongly acuminate, interstriae 2 minutely reticulate, its lateral margin more strongly impressed; Jalisco to Honduras; Pinus; 1.5-1.7 mm
145. cacuminatus Blandford

- Female frons more narrowly, more sparsely pubescent, flattened area separated from margin of eye by at least diameter of four facets, punctures coarser, not as close; body 3.1 times as long as wide; declivity not as steep, apex more strongly acuminate, interstriae 2 smooth, usually shagreened (slightly), its lateral margin not impressed; Oaxaca to Guatemala; Pinus; $1.3-1.7 \mathrm{~mm}$ (see also couplet 209)

209. subsimilis Schedl

147(145). Female frons partly to extensively flattened, more finely, more densely punctured, varying from glabrous to elaborately ornamented by short or long setae; discal interstriae only slightly wider than striae, a few interstrial punctures usually present; body 3.1 times as long as wide; Alaska and Manitoba to California and Arizona; Pinus; $1.8-2.4 \mathrm{~mm}$
146. murrayanae Blackman

- Female frons more strongly convex, more coarsely punctured, vestiture usually absent, sometimes short and rather sparse; discal interstriae about twice as wide as striae, almost never with any interstrial punctures; body 2.9 times as long as wide

| 148(147). | Declivital interstriae 1 and 3 unarmed or granules very feeble; male frons |
| :--- | :--- |
| with elevation obscure to absent, female frons flattened on a larger area, |  |
| more finely, more closely punctured; NE British Columbia and Nova Scotia |  |
| to E Texas and Florida; Pinus; $1.3-1.7 \mathrm{~mm} . . . . . . . . . . . . . . . . ~ 147 . ~ c o n s i m i l i s ~ L e C o n t e ~$ |  |

149(137). Mostly smaller than 2.3 mm (except grandis); sutural apex subacuminate, sutural profile at least weakly convex, more strongly so near apex

- Larger than 2.5 mm ; sutural apex very strongly, acutely acuminate (except megas), sutural profile straight, often slightly concave near apex (except female megas)
150(149). Male and female frons similarly sculptured, with a conspicuously elevated transverse carina at upper level of eyes; elytral punctures coarse, deep, strongly confused
- Male frons with a transverse carina; female frons flattened or weakly concave, more finely, densely punctured, with or without a brush of hair, without a carina

151(150). Transverse impression on lower frons shallow, sculpture much finer; elytral declivity steeper, sulcus not as wide; Michigan and New York to E Texas and South Carolina; Pinus; 1.8-2.6 mm ........................ 149. pullus (Zimmermann)

- Frons below upper level of eyes rather strongly, transversely impressed, its sculpture rather coarse; elytral declivity more gradual, sulcus distinctly wider; British Columbia and South Dakota to Arizona and New Mexico; $2.3-3.1 \mathrm{~mm}$

150. grandis Blackman

152(150). Discal punctures on elytra rather strongly confused; female pronotum usually stouter 1.0-1.1 times as long as wide; female frons flat or with a transverse impression, punctures finer, more dense, vestiture more abundant (usually) and with setae in central area rather long, at least half as long as those on margins

- Discal punctures largely or entirely in rows; female pronotum usually more slender, 1.2-1.3 times as long as wide; female frons weakly convex to weakly concave, punctures fine to moderately coarse, less abundant, vestiture variable

153(152). Declivital interstriae 1 unarmed by tubercles, lateral convexities very strongly elevated, summit conspicuously higher than suture and armed on upper two-thirds by a row of $10-14$ moderately coarse denticles; British Columbia and Idaho to California; Pinus ponderosa; 2.1-2.2 mm 151. serratus Swaine

- Elytral declivity with interstriae 1 armed by a few fine tubercles, lateral convexities about as high as interstriae 1 and armed by about 3-6 fine denticles; British Columbia and Montana to California and Hidalgo; Pinus; $1.8-2.3 \mathrm{~mm}$
154(152). Female frons moderately convex to flattened on a limited area extending to only slightly above upper level of eyes, vestiture sparse, rather short to obsolete; declivity usually steeper, sulcus deeper 155
- Female frons broadly flattened to well above eyes, vestiture abundant, long; declivity usually more gradual, sulcus not as deep (except very deep in bassetti)

155(154). Declivity slightly steeper, striae 1 and 2 clearly punctured, interstriae 2 only slightly wider than 1 ; female frons with a slight median callus at upper level of eyes, vestiture slightly more abundant and longer in lateral areas; Arizona; Pinus ponderosa; $2.0-2.1 \mathrm{~mm}$
153. clarus Blackman

Declivity not quite as steep, striae 1 and 2 with punctures minute, obscure,
interstriae 2 about twice as wide as 1 ; female frons without median callus,
vestiture less abundant, shorter ........................................................................... 156
156(155). Female frontal vestiture extending slightly above eyes, more abundant, longer; pronotal and elytral dises smoother; declivital sulcus distinctly wider and deeper, more strongly reticulate, vestiture slightly longer; Oaxaca; 1.9-2.2 mm
154. solatus Wood

- Female frontal vestiture not extending above eyes, vestiture less abundant, shorter; pronotal and elytral dises usually with impressed points or other irregularities, not as smooth; declivital sulcus slightly narrower, not as deep, obscurely reticulate, vestiture slightly shorter; Utah to Chihuahua; Abies; $1.5-2.1 \mathrm{~mm}$

155. solers Blackman

157(154). Sutural interstriae on declivity unarmed in male, fine, sparse tubercles sometimes present in female; lateral convexities of declivity in male much higher than suture, summit armed by 8-12 rather coarse denticles; female frons variable, glabrous to rather densely pubescent, longest setae equal to as much as half distance between eyes; Northwest Territories to Chihuahua; Picea; $1.8-2.4 \mathrm{~mm}$
156. bassetti Blackman

- Sutural interstriae armed by tubercles in both sexes, lateral convexities as high as suture; pronotal asperities either confused or subconcentric; female frons flat to plano-concave, punctures rather fine to very fine, close

158(157). Female frons more extensively flat to plano-concave, more than one-third of flattened area above upper level of eyes, punctures minute, spaced by one to four diameters of a puncture, vestiture more abundant, longer; pronotal asperities confused, punctures on posterior areas usually armed by a minute granule on lateral or posterior margin; declivital sulcus deeper, apparently narrower; strial hair longer on posterior half; Chihuahua to Guatemala; Pinus; $\mathbf{1 . 6 - 2 . 1 ~ m m ~}$
157. delicatus Wood

- Female frons flat to plano-convex, one-fourth or less above upper level of eyes, punctures larger, spaced by less than diameter of a puncture; pronotal asperities subconcentric, punctures never with a granule on margins; declivital sulcus not as deep, apparently narrower; strial hair very short, not longer on declivity; Nevada to Arizona and W Texas; Pinus ponderosa; 1.7-1.8 mm 158. arcanus Bright

159(149). Smaller; discal striae with punctures in definite rows, interstriae without punctures; declivital suture usually as high as lateral convexities

- Larger; punctures on elytral disc confused or at least with interstriae punctured; declivital lateral convexities usually much higher than suture

160(159). Declivital striae 1 and 2 strongly punctured, sulcus rather shallow; female frontal vestiture very long, unusually dense; Arizona to Nuevo León; Pinus; 2.2 mm
159. zonalis Bright

- Declivital striae 1 with punctures obsolete, 2 punctured or not; sulcus much more strongly impressed

161(160). Declivity much less strongly impressed, interstriae 2 less than twice as wide as 1 , its base rarely with punctures, almost never with a granule; declivital interstriae 1 usually with more than seven setae; Durango to Mexico and Veracruz; Pinus; 1.6-2.3 mm
160. cuspidatus Blackman

- Declivity strongly impressed, interstriae 2 almost three times as wide as 1 , its base almost always armed by one or more tubercles; declivital interstriae 1 usually with five or fewer setae; Utah and Colorado to Arizona and New Mexico; Pinus flexilis, $P$. strobifornis; $2.0-2.3 \mathrm{~mm}$

161. acutus Blackman

162(159). Declivity not as steep, apex very strongly acuminate, interstriae 1 usually unarmed through more than middle half of its length, interstriae 2 reticulate; body more slender, 2.8-3.0 times as long as wide; color very dark brown; Chihuahua to Oaxaca and Veracruz; Pinus; 2.4-2.8 mm
162. spadix Blackman

- Declivity very steep, apex subacuminate to moderately acuminate, interstriae 1 armed throughout (usually); body 2.6-2.8 times as long as wide .... 163

163(162). Smaller; color reddish brown; elytral apex moderately acuminate; body 2.6 times as long as wide; strial setae minute, their length less than twice diameter of puncture from which they arise; Arizona to Durango; Pinus engelmannii; $2.4-2.7 \mathrm{~mm}$
163. rubidus Wood

- Larger; very dark brown; elytral apex weakly subacuminate; body 2.8 times as long as wide; strial setae very long, some more than four times diameter of puncture from which they arise; Nuevo León; Pinus culminicola; 3.5-3.7 mm

164. megas Bright

164(1,136). Base of declivital interstriae 2 with a row of puncture or tubercles or both (not always evident in barberi), punctures may or may not occur on disc . 165

- Interstriae 2 entirely devoid of punctures or tubercles on disc or declivity (except on lower declivity in lautus) (three species with pronotal asperities confused)
165(164). Declivital interstriae 2 moderately impressed, only slightly wider than 1 or 3 , armed by a row of fine setiferous tubercles or punctures as on 1 and 3, setae equal in length to those on 1 ; discal interstriae impunctate; frons similar in both sexes, convex, punctured, vestiture inconspicuous, without a carina
- Declivital interstriae 2 without setae, punctures, or tubercles on face of declivity, much wider than 1 or 3 ; frons usually sexually dimorphic, male usually with a transverse carina, female often pubescent
166(165). Pronotum reticulate; discal interstriae 1 impunctate; declivital interstriae 2 on upper half with a row of fine granules; color dark brown; Honduras to Costa Rica; Aristolchia anguicida; $1.4-1.8 \mathrm{~mm}$ 165. nemoralis Wood
- Pronotum smooth, shining; discal interstriae 1 with a row of punctures; declivital interstriae 2 with a row of punctures; color yellowish brown; Florida to Cuba; Metopium toxiferum; 1.2-1.5 mm 166. concentralis Eichhoff

167(165). Posterior areas of pronotum reticulate; declivital striae 1 and 2 with punctures reduced, much smaller than on disc; basal half of declivital sulcus less strongly impressed, apex rather strongly acuminate

- Posterior areas of pronotum smooth, shining; declivital striae 1 and 2 rather coarsely punctured; declivital sulcus often deeper, apex not acuminate (except mexicanus)

168(167). Smaller; female frons less strongly impressed, vestiture yellowish, shorter, less abundant, longest setae equal to less than one-third distance between eyes; lateral convexities of declivity only slightly higher than suture; Jalisco; Sambucus; 1.4-1.9 mm
167. coronarius Blackman

- Larger; female frons more strongly impressed, vestiture reddish brown, longer, much more abundant, longest setae equal to more than half distance between eyes; lateral convexities of declivity distinctly higher than suture; "Plaquepaque, Mexico"; in unidentified wood; 1.7-2.3 mm

168. concinnus Wood

169(167). Declivity shallowly, broadly sulcate, surface of interstriae 2 subreticulate to abundantly marked by minute impressed points, apex rounded, not at all acuminate; female frons sparsely pubescent; host Pinus

- Declivity usually more strongly impressed, its surface smooth, brightly shining, elytral apex moderately to strongly acuminate; female frons with moderately to very abundant pubescence; hosts desert shrubs

170(169). Discal interstriae regularly punctured; male frons shallowly impressed from epistoma to upper level of eyes, transverse carina obscure, female similar but more weakly impressed and with a few moderately long setae; granules on declivital interstriae 1 and 3 fine; California to Oregon; Pinus jeffreyi; $1.7-1.9 \mathrm{~mm}$
169. jeffreyi Blackman

- Discal interstriae mostly to entirely impunctate; transverse carina at or slightly below upper level of eyes, strongly developed in male, rather weak in female; female frontal vestiture short, sparse; tubercles on declivital interstriae 3 larger; Utah and Colorado to Durango and Nuevo León; Pinus edulis; 1.7-2.2 mm

170. barberi Blackman

171(169). Larger species; male frons convex, without a carina; declivity more gradual, apex more distinctly acuminate, interstriae 1 armed by a row of small tubercles (see also coronarius, concinnus)

- Smaller species; male frons transversely impressed, a distinct transverse carina at upper level of eyes; declivity steeper, apex indistinctly subacuminate, interstriae 1 unarmed except for one or two small granules near apex

172(171). Pronotal disc finely, rather sparsely punctured; all discal interstriae with a few punctures on posterior half; declivity shallowly sulcate, suture as high as interstriae 3, apex subacuminate; New Mexico 171. torridus Wood

- Pronotal disc coarsely, closely punctured; discal interstriae impunctate except 2; declivity strongly sulcate, interstriae 3 much higher than 1 , apex strongly acuminate; Coahuila to Jalisco and Tabasco; Parthenium argentatum; 2.0-2.9 mm .................................................. 172. mexicanus Blackman

173(171). Declivity much more shallowly impressed, lateral areas on lower half not flattened, more regularly rounded, tubercles on lateral margins smaller; Texas to North Carolina and Georgia; Rhus; 1.3-1.5 mm

- Declivity more deeply, broadly sulcate, lateral areas on lower half weakly to moderately flattened; average size slightly larger
174(173). Male declivity obscurely flattened on median half on lower half, lateral margin subacute only near apex; punctures on female frons very fine; Utah and Wyoming to Chihuahua and W Texas; Rhus; $1.4-1.8 \mathrm{~mm}$
Male declivity somewhat flattened on lower half, lateral margin from apex
to above middle weakly, subacutely elevated; punctures on female frons
moderately coarse; Hidalgo; Rhus; $1.4-1.7 \mathrm{~mm} . . . . . . . . . . . . .175$. hylocuroides Wood

175(164). Elytral declivity convex or at most with striae 1 impressed, punctures on
striae 1 and 2 often reduced or obsolete, granules on lateral convexities small
or absent

- Elytral declivity moderately to strongly sulcate, interstriae 2 impressed, striae 1 and 2 usually clearly punctured, granules on lateral convexities small to moderately coarse (see also male nanus) (asperities confused on three tropical species)

176(175). Concentric rows of pronotal asperities forming continuous costae; summit of each costa weakly subserrate, clefts between dentations, restricted to distal third of height of costa or less; male frons convex, punctured, without a carina, female frons moderately, flattened, vestiture rather short; declivital striae 1 and 2 much more coarsely punctured in female, punctures minute to almost obsolete in male; pronotum with numerous, deeply impressed points; suture 1 on antennal club clearly septate, 2 obscurely septate

- Asperities in concentric rows more strongly serrate, divided to or near their bases

177(176). Sutures of antennal club straight to moderately procurved; declivital striae 1 and 2 more finely punctured in both sexes, interstriae 2 weakly impressed in female; male frons subglabrous; Jalisco to Oaxaca; Thevetia; 0.9-1.3 mm
176. costatulus Wood

- $\quad$ Sutures of antennal club strongly procurved; declivital interstriae 1 and 2 rather coarsely punctured in female, interstriae 2 moderately impressed; male epistomal brush rather conspicuous; Jalisco; possibly Thevetia; 1.6-1.8 mm

177. costabilis Wood

178(176). Elytral declivity convex, interstriae 1 weakly, gradually elevated or not,
striae 1 not impressed ..... 179

- Elytral declivity convex to weakly sulcate, striae 1 abruptly impressed ..... 181

179(178). Declivity more broadly convex, punctures on striae 1 and 2 minute; male frons moderately, transversely impressed from epistoma to upper level of eyes; female frons minutely punctured, longest setae on vertex too short for tips to reach epistomal margin, epistomal margin of normal coloration; Michoacán to Queretaro; Rhus; $1.4-1.8 \mathrm{~mm}$
178. detentus Wood

- Declivity more narrowly convex, punctures on striae 1 and 2 moderately coarse; male frons convex; female frons with setae on vertex very long, their tips capable of extending beyond epistomal margin, epistomal area pale yellow; antennal club with sutures almost obsolete 180

180(179). Pronotum reticulate; elytral disc with numerous clearly impressed points; frons more finely punctured, male reticulate from epistoma to upper level of eyes; Costa Rica; 1.1-1.2 mm
Pronotal disc smooth, shining; elytral disc with impressed points obscure to
obsolete; frons rather coarsely punctured, male without reticulation below
upper level of eyes; Chiapas to Costa Rica; Mauria glauca; 1.2-1.4 mm ........ 180. debilis Wood

[^20]Male frons weakly to moderately impressed, usually with a transverse crest
or carina at upper level of eyes; mostly smaller species, $1.1-1.5 \mathrm{~mm}$............... 184
182(181). Sutures of antennal club straight; anterior margin of pronotum armed by
about 20 serrations; California and New Mexico to Chihuahua; Juglans;
$1.5-1.9 \mathrm{~mm} . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . j u g l a n d i s ~ B l a c k m a n ~$
183(182). Declivity bisulcate, interstriae 2 moderately impressed; punctures on
pronotal disc rather coarse, close; Guatemala; $1.6-1.7 \mathrm{~mm} . . . . . . .182$. tenax Wood

- Declivity convex, interstriae 2 not impressed; punctures on pronotal disc fine, rather widely spaced, Costa Rica; Rheedia edulis; 1.3 mm

183. strictus Wood

184(181). Declivital interstriae 1 armed by a row of fine granules; male frons armed by a strongly, subacutely elevated transverse carina; female frons flattened on a rather narrow area, vestiture moderately abundant, uniformly short, uniformly distributed; color very dark brown; New Mexico; Franseria; 1.2-1.4 mm
184. franseriae Wood

- Declivital interstriae 1 unarmed; male frontal carina weak if present; color yellowish brown185
185(184). Female frons with lateral margins rounded, pubescent area less extensive, setae on margins not longer than elsewhere; declivity moderately sulcate ..... 186
- Lateral margins of female frons abruptly subangulate; pubescent area more extensive, extending to vertex, setae on margins conspicuously longer: declivity weakly or not at all sulcate
186(185). Female frons rather densely, finely punctured on lower half, this area covered by dense, very long, mustachelike pubescence; male frons more strongly impressed, summit at upper level of eyes more conspicuous; female declivity shallow, granules almost obsolete on lateral convexities, male sulcus much deeper, lateral convexities conspicuously higher than suture, armed by two to four moderately coarse tubercles; Jalisco to Chiapas; Bursera; 1.2-1.5 mm

185. nanus Wood

- $\quad$ Female frons rather coarsely punctured, pubescent area extending to slightly above eyes, setae rather sparse, uniformly rather short; male frons weakly impressed, carina not indicated; declivity shallowly sulcate, lateral convexities sometimes slightly higher than suture, granules minute
187(186). Female frons flat, pubescence shorter, surface more finely, more sparsely punctured; pronotal asperities in clearly concentric rows; pronotal dise and elytral declivity shining; declivity more strongly sulcate, lateral convexities higher than suture, granules minute; Costa Rica; Rheedia edulis; 1.1-1.2 mm

186. galeritus Wood

- Female frons transversely impressed to upper level of eyes, surface more coarsely, more closely punctured; pronotal asperities largely confused, only first two rows obscurely concentric; pronotal disc and elytral declivity shagreened; declivity obscurely sulcate, suture and lateral convexities subequal in height, unarmed; Veracruz; Bursera; 1.4-1.7 mm

187. nebulosus Wood

188(185). Declivity more narrowly convex, interstriae 2 weakly impressed on mesal side, punctures on striae 2 distinctly larger; declivital setae usually slightly shorter, stouter; female frontal vestiture apparently shorter, less abundant; Jalisco to Oaxaca; Bursera; 1.2-1.4 mm
188. indigens Wood

|  | Declivity more broadly convex, interstriae 2 more broadly, more distinctly impressed, punctures on striae 2 minute; declivital setae longer, more slender; female frontal vestiture longer, apparently more abundant; Jalisco; <br> Bursera; 1.5-1.6 mm $\qquad$ 189. burserae Wood |
| :---: | :---: |
| 189(175). | Lower half of declivity much steeper, often subvertical, apex much more broadly rounded, interstriae 2 more strongly impressed, tubercles on 3 usually smaller; body usually stouter; pubescence on female frons sparse, short, inconspicuous (except long in crinalis and liquidambaris) $\qquad$ 190 |
| - | Lower half of declivity more gradual, apex narrowly rounded to subacuminate, interstriae 2 usually less strongly impressed, tubercles on 3 usually larger; body usually more slender; female frons usually ornamented by long, more abundant setae, male frons with few setae, usually transversely impressed (asperities confused on three tropical species) $\qquad$ 205 |
| 190(189). | Female frons with pubescence sparse, short; frons weakly if at all sexually dimorphic $\qquad$ 191 |
| - | Female frons ornamented by several to many long setae; frons conspicuously sexually dimorphic $\qquad$ 203 |
| 191(190). | Elytral declivity very steep, subvertical on more than lower half, interstriae 2 strongly impressed, not wider than 1 , sometimes extending to posterior fourth of disc, lateral areas on lower half broadly elevated, denticles on 3 mesad of crest; on Pinus (except host unknown for germanus); from Mexico to Hondurus $\qquad$ 192 |
|  | Elytral declivity steep, lateral areas on lower half less strongly elevated, denticles on 3 on crest; never on coniferous hosts (except lautus accidentally). 195 |

- Pronotal disc smooth and shining, more coarsely punctured; female frons moderately to densely pubescent 208

208(207). Elytral declivity more narrowly, rather weakly sulcate, interstriae 1 and 3 tuberculate in both sexes, apex acuminate; vestiture on female frons of uniform length; Panama; in log; 1.3-1.5 mm 207. vesculus Wood

- Elytral apex rounded, not acuminate, sulcus much wider and deeper, interstriae 1 and 3 unarmed in female, rather coarsely tuberculate in male, each with 2-4 tubercles; female frontal vestiture much longer on margins; Costa Rica; tree limb 1.5-1.7 mm

208. sparsepilosus (Schedl)

209(206). Declivity more gradual, sulcus deeper, punctures on striae 1 small to minute, less than half as large as those on dise

- Declivity steeper, sulcus not as deep, punctures on striae 1 subequal in size to those on disc 211

210(209). Pronotal asperities almost always confused; declivital striae 1 rather coarsely punctured; male frons more distinctly impressed, carina moderately strong; female frons usually more coarsely punctured, vestiture coarser, usually longer; Puebla to Chiapas; Pinus; 1.1-1.7 mm (see also couplet 146)
209. subsimilis Schedl

- Pronotal asperities almost always concentric; declivital striae 1 with punctures small to obsolete; male frons feebly impressed, carina very weak; female frons usually more finely punctured, vestiture usually finer, shorter; Jalisco and Veracruz to Guatemala; in shrubs; $1.2-1.5 \mathrm{~mm}$

210. attenuatus Blackman
$211(210)$. Male frons with a fine, low, distinct, transverse carina at upper level of eyes; declivital striae 2 not distinctly impressed; female frons flattened on a smaller area, plano-convex, punctures more numerous; Veracruz to Oaxaca; shrub; $0.8-1.1 \mathrm{~mm}$
211. atomus Wood

- Male frons devoid of carina; female frons slightly, transversely impressed to upper level of eyes, sparsely punctured in central area; declivital striae 2 impressed; pronotum finely reticulate on posterior half

212(211). Female frons narrowly flattened to upper level of eyes, pubescence moderately abundant, rather short, not conspicuously longer laterally; declivity not as steep, more distinctly impressed; "Mexico"; 1.2 mm (see also 213. timidus Blandford)
212. dimidiatus Blackman

- Female frons more distinctly, transversely impressed, more sparsely punctured, setae in lateral areas longer; declivity slightly steeper, less strongly impressed; Costa Rica to Panama; 1.0-1.2 mm

214. perexiguus Wood

213(205). Female epistomal margin on median half extended into a pubescent subacutely pointed premandibular process; male frons convex without a carina or other elevation at upper level of eyes; Guatemala; liana; 1.2-1.3 mm $\qquad$ 215. nugalis Wood

- Female epistomal margin normal, almost straight, male frons with a carina or other distinct elevation at upper level of eyes 214

214(212). Pronotum finely reticulate; female frons ornamented by a dense brush of very long hair; Honduras; Eupatorium, Perymanium; 1.0-1.3 mm $\qquad$ 216. hermosus Wood

- Pronotum smooth, shining, with numerous impressed points; female frons with vestiture less abundant, somewhat shorter 215

215(214). Declivital interstriae 2 less strongly impressed, ascending laterally, striae 2 not impressed, punctures small; female frons plano-convex, longest setae equal to one-third distance between eyes; Guatemala; shrub; 0.9-1.0 mm ......
217. minutalis Wood

- Declivital interstriae 2 more strongly impressed, flat, striae 2 slightly impressed, punctures half as large as on dise; female frons planoconcave on central half, longest setae equal to more than half distance between eyes; Costa Rica; liana; $1.5-1.7 \mathrm{~mm}$

218. sobrinus Wood

## 1. Pityophthorus costatus Wood

Pityophthorus costatus Wood, 1975, Creat Basin Nat. 35:395 (Holotype, female; Tapantí, Cartago, Costa Rica; Wood Coll.)
Diagnosis.- This aberrant species has a variable number of segments in the antennal funicle; it is also distinguished by the long, costiform pronotal asperities, by the stout body form, by the frons, and by other characters.

Female.- Length $1.1-1.2 \mathrm{~mm}, 2.3$ times as long as wide; color dark reddish brown.

Frons rather strongly convex, an abrupt, moderately deep impression immediately above epistomal margin, epistomal margin distinctly elevated except for small median notch; surface smooth shining, sparsely punctured, punctures rather coarse, area above eyes somewhat reticulate; vestiture very sparse, short. Antennal funicle variable, 3-5segmented; club ovate, small, sutures almost straight, 1 and 2 septate only at margins.

Pronotum 1.0 times as long as wide; widest at base, weakly arcuate on basal third, rather strongly converging toward narrowly rounded anterior margin; anterior margin continuously costate; summit just behind middle, rather indefinite, asperities long, subcostate, confused, continued to basal fourth
in median area; posterior areas strongly reticulate, punctures small, not close. Glabrous.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, punctures small, deep, spaced by one to two diameters of a puncture; interstriae smooth, shining, two to three times as wide as striae, punctures minute, confused, rather close. Declivity steep, convex; striae not impressed, punctures greatly reduced to obsolete; interstriae as on disc except punctures reduced to obsolete. Vestiture confined to declivity, of sparse, short, stout interstrial setae.

Male. - Similar to female except epistomal impression usually more strongly impressed in lateral areas, with a weak median elevation dividing this impression.
Distribution. - Costa Rica.
COSTA RICA: I3 km SE Cartago, Cartago, 3-VII-63, 1800 m, No. 11b, liana, S. L. Wood; Tapantí, Cartago, 2-VII-63, 1300 m , No. 11a, liana, S. L. Wood.
Notes. - The above treatment was based on the type series of 17 specimens.

## 2. Pityophthorus pudicus Blackman

Pityophthorus pudicus Blackman, 1942, Proc. U.S. Nat. Mus. 92:208 (Holotype, male; Guadalajara, Jalisco, Mexico; U.S. Nat. Mus., 55983)

Diagnosis.- This species is distinguished from exquisitus Blackman by the smaller size, by the less coarsely punctured pronotum and elytra, and by the less strongly convex male frons.

Female.- Length 1.3-1.5 mm, 2.6 times as long as wide; color very dark brown.

Frons as in exquisitus except more nearly flat on lower fourth.

Pronotum as in exquisitus except less strongly reticulate, punctures averaging distinctly smaller.

Elytra as in exquisitus except punctures averaging smaller, particularly near declivity; interstriae about as wide as striae on basal half of disc (interstriae about twice as wide as exquisitus).

Male.- Similar to female, with frons as in male exquisitus except less strongly convex on lower half.

Distribution- Jalisco.
Mexico: Jalisco: Volcán Colima, 23-V1-65, 2500 m . No. 107, shrub, S. L. Wood, intercepted at New York in Sambucus wood from Guadalajara.

Notes. - The above treatment was based on the holotype and on 16 other specimens.

## 3. Pityophthorus exquisitus (Blackman) Fig. 198

Ncodryococtes exquisitus Blackman, 1942. Proc. U.S. Nat. Mus. 92:196 (Holotype, female; Mexico; U.S. Nat. Mus., 55977)
Pityophthorus inceptis Wood, 1975. Great Basin Nat. 35:396 (Holotype, female; 4 miles or 6 km W Quiroga, Michoacán, Mexico; Wood Coll.). Neu synonymy
Diagnosis.- This species is distinguished by the simple male frons and declivity, by the female frontal vestiture, and by the coarse pronotal and elytral punctures. It is not closely allied to other known species.

Female.- Length 1.5-1.6 mm, 2.7 times as long as wide; color very dark brown.

Frons basically convex except flattened on median half from epistoma to slightly above eyes; surface shining, punctures rather coarse, moderately close; vestiture rather sparse and short except on margins of upper half of flattened area, there forming a dense fringe of long, yellow hair, longest setae equal in length to three-fourths distance from their bases to epistomal margin. Antennal club broadly obovate, 1.2 times as long as wide,
suture 1 almost straight, 2 moderately procurved.

Pronotum 1.07 times as long as wide; widest on basal third, moderately arcuate from base to rather broadly rounded anterior margin; anterior margin armed by about six to eight low, basally contiguous teeth; summit at middle; asperities rather coarse, confused; posterior areas subrugose-reticulate, punctures coarse, deep, mostly spaced by distances equal to one-half diameter of a puncture, median line impunctate. Vestiture of sparse semirecumbent short hair in lateral and asperate areas.

Elytra 1.7 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal three-fourths, somewhat narrowly rounded behind; striae not impressed, punctures rather coarse, deep, occasional punctures not in row, spaced by less than diameter of a puncture; interstriae almost smooth, shining, impunctate except for an occasional puncture near declivity. Declivity steep, convex; striae not impressed, punctures reduced, about one-third as large as on disc, distinctly impressed; interstriae as on dise except 1 and 3 each with a row of fine punctures. Vestiture confined to sides and declivity, that on sides of minute strial hair, that on declivity of fine, rather short interstrial setae on odd-numbered interstriae.

Male. - Similar to female except frons more uniformly convex, without brush of long hair; serrations on anterior margin of pronotum slightly larger.

Distribution.- Michoacán to Jalisco.
MEXICO: Jalisco: Guadalajara, $30-\mathrm{xil}-42$, in pottery crate wood; Tlaquepaque, $7-\mathrm{XI}-41$, Sambucus canes intercepted at New York 91171. Michoacán: 6 km W Quiroga, 17-VJ-65, 2200 m , No. 72, shrub, S. L. Wood.

Notes.- The above treatment was based on the type series of three specimens. This species should probably be placed in Araptus near speciosus Wood; the type series are not sufficient to adequately place it.

## 4. Pityophthorus melanurus Wood

Pityophthorus melanurus Wood, 1976, Great Basin Nat. 36:364 (Holotype, female?; 5 miles or 8 km W San Cristóbal de las Casas, Chiapas, Mexico; Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from alni Blackman by the smaller average
size, by the rugose-reticulate pronotal surface, by the coarser pronotal rugae on the posterior half, by the wrinkled elytral surface, and by other characters described below.

Female(?).- Length $1.7-2.0 \mathrm{~mm}, 3.0$ times as long as wide; color black.

Frons broadly convex, a slight transverse impression immediately above epistoma; surface reticulate, punctures fine, rather sparse; vestiture fine, short, sparse. Antennal club 2.0 times as long as wide, sutures 1 and 2 straight, not marked by grooves or setae on middle half.

Pronotum 1.16 times as long as wide; outline about as in alni; anterior margin armed by about 16 rather coarse serrations; longitudinal rugae extending to base as in alni except much coarser on disc; surface between asperities and rugae rugose-reticulate, punctures not clearly evident. Vestiture restricted to margins and asperate area.

Elytra 1.8 times as long as wide, 1.6 times as long as pronotum; outline as in alni; striae not impressed, moderately to strongly confused, 1 and 2 often distinguishable on posterior half; surface shining, wrinkled, interstrial punctures similar to and largely confused with those of striae. Declivity steep, convex: sculpture as on disc, striae 1 and 2 slightly confused but identifiable, their punctures almost as large as on disc; interstrial punctures not granulate. Vestiture extending to base, similar on dise and declivity; consisting of moderately coarse, rather long strial hair and similar interstrial setae, interstrial setae on declivity slightly longer.

Distribution.-Chiapas.
MEXICO: Chiapas: San Cristobal de las Casas, 3-10-V-69, beating Quercus, H. F. Howden.

Notes. - The above treatment was based on the type series of four specimens, apparently all females.

## 5. Pityophthorus alni Blackman

 Fig. 200Pityophthorus alni Blackman, I942, Proc. U.S. Nat. Mus. 92:209 (Holotype, female; Jalapa, Veracruz, Mexico; U.S. Nat. Mus., 55984)
Diagnosis.- This species is distinguished by the near absence of secondary sexual characters, by the unique pronotum, by the spatulate interstrial setae, and by other characters.

Female.- Length $2.0-2.4 \mathrm{~mm}, 2.8$ times as long as wide; color black.

Frons convex on upper half, lower half shallowly, transversely impressed with median area weakly elevated; surface shining, punctures on marginal areas rather coarse, deep, close, becoming smaller and granulate toward central half, central third on lower half rather sparsely punctured, without granules, a few subaciculate lines usually present; vestiture of sparse, fine, rather long hair below upper level of eyes. Antennal club 1.3 times as long as wide, slightly wider through segment 3 , sutures 1 and 2 weakly prscurved.

Pronotum 1.2 times as long as wide; sides almost straight and parallel on basal third, then arcuately converging to broadly rounded anterior margin; anterior margin subserrately costate; summit at middle; asperities moderately large, confused, decreasing in size behind summit, continued almost to base as declining costae in lateral areas; posterior areas between costae etched with minute points, punctures moderately coarse, rather close. Glabrous except for a few short setae on lateral margins and in asperate area.

Elytra 1.8 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather narrowly rounded behind: striae 1 slightly, others not impressed, punctures rather coarse, deep, close; interstriae smooth, shining, twice as wide as striae, small, uniseriate, restricted to base and to near declivity. Declivity convex, steep; sculpture similar to disc except interstriae 1 weakly elevated, striae 1 more strongly impressed, strial punctures less than half as large, interstriae uniseriately punctured (sparse on 2), most punctures finely granulate. Vestiture confined to declivity, of minute strial hair and erect, spatulate interstrial bristles, each two-thirds as long as distance between rows, more widely spaced within a row.

Male- Similar to female in all respects.
Distribution.- Hidalgo to Veracruz.
MEXICO: Hidalgo: Tlahuehumpa, Zacultipan, 16-N80, Alnus. T. H. Atkinson. Veracruz: Las Vigas, 5-VII67, Almus, S. L. Wood; Jalapa, 9-II-36, Alnus, D. DeLeon.

Notes.- The above treatment was based on the holotype and on six other specimens.

## 6. Pityophthorus alnicolens Wood

Pityophthorus alnicolens Wood, 1977, Great Basin Nat. 37:213 (Holotype, male?; Highway 131, 115 miles or 184 km S Oaxaca, Oaxaca, Mexico; Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from alni Blackman by the smaller size, by the reticulate, dull pronotum, by the smaller, less deeply impressed strial punctures, and by the proportionately wider discal interstriae, which have numerous, irregular, impressed lines.

Male(?).- Length $1.5-1.7 \mathrm{~mm}, 2.6$ times as long as wide; color dark brown.

Frons broadly convex, flattened on lower half, a very feeble median carina from epistoma to upper level of eyes; epistomal margin slightly elevated; vestiture sparse, short, inconspicuous. Antennal club as in alni except slightly smaller, slightly more slender.

Pronotum much as in alni except discal area strongly reticulate, punctures coarser, margins not asperate; asperities absent from posterior third.

Elytra much as in alni except striae not impressed, punctures much smaller, not as deep, interstriae three times as wide as striae, with fine, irregular impressed lines and points, with fine, rather sparse, uniseriate punctures. Declivity about as in alni except punctures much finer. Vestiture about as in alni except much longer.

Distribution.- Oaxaca.
MEXICO: Oaxaca: Highway 131, 115 miles or 184 km S Oaxaca, 27-30-V-71, 6000 ft , Almus, D. E. Bright.

Notes. - The above treatment was based on the type series of five specimens.

## 7. Pityophthorus elegans Schedl

Pityophthorus elegans Schedl, 1938, Archiv Naturgesch. 7:184 (Holotype, male; Guatemala; U.S. Nat. Mus., 60251)
Diagnosis.- This species is distinguished from the remotely allied sparsepilosus (Schedl) by the smaller size, by the more slender form, and by other characters cited below.

Male.- Length $1.3 \mathrm{~mm}, 3.1$ times as long as wide; color brown.

Frons moderately, transversely impressed from epistoma to upper level of eyes, upper margin of impression rather abrupt but not carinate, surface almost smooth, shining,
punctures rather small, moderately close except impunctate on a small median area on lower fourth.

Pronotum 1.2 times as long as wide; sides almost straight and parallel on basal half, rather broadly rounded in front, anterior margin armed by 12 rather low, equal serrations; summit anterior to middle; asperities small, rather numerous, confused; posterior areas smooth, shining, impressed points present (mostly covered by debris), punctures rather small, moderately close.

Elytra 1.8 times as long as wide, 1.6 times as long as pronotum; striae not impressed, punctures moderately coarse; interstriae shining, almost smooth, many impressed points present, almost twice as wide as striae, punctures absent. Declivity steep, rather strongly bisulcate, lateral areas superficially appear slightly flattened; punctures on striae 1 evidently obsolete, distinctly, rather coarsely impressed on 2 ; interstriae 1 distinctly elevated, with a few fine granules, 2 rather strongly impressed, about one and one-half times as long as wide, somewhat flat, lateral areas rather broadly rounded, upper half very slightly higher than suture, granules fine. Vestiture of stout setae of moderate length on and near declivity on odd-numbered interstriae, rather close.

Distribution.- Guatemala.
"Guatemala, Conradt."
Notes.- The above treatment was based on the holotype.

## 8. Pityophthorus timidulus Wood

Pityophthorus timidulus Wood, 1975, Great Basin Nat. 35:396 (Holotype, male; Volcán Chiriquí, Chiriquí, Panama; Wood Coll.)
Diagnosis.- This species is distinguished from mendosus Wood by the larger size, by the coarser pronotal punctures, and by slight differences on the elytral declivity. Both species are allied to mandibularis Schedl

Male.- Length $1.8-2.0 \mathrm{~mm}, 2.5$ times as long as wide; color very dark brown.

Frons convex above eyes, upper half of area below upper level of eyes rather abruptly, strongly, transversely impressed almost from eye to eye, a smaller transverse impression in lateral areas immediately above epistoma; surface shining, coarsely, rather closely
punctured; vestiture sparse except on epistoma. Antennal club oval, 1.3 times as long as wide, sutures 1 and 2 moderately arcuate, 2 at middle of club.

Pronotum 1.1 times as long as wide; sides on basal half almost straight, subparallel, rather broadly rounded in front; anterior margin armed by about 12 low serrations; summit at middle; asperities on anterior slope rather coarse, close, confused; posterior areas smooth, shining, with moderately abundant minute impressed points, punctures rather coarse, deep, moderately close, irregularly spaced by about one to two diameters of a puncture. Glabrous except a few setae on margins.

Elytra 1.6 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae 1 weakly, others not impressed, punctures rather small, deep, spaced by diameter of one puncture; interstriae smooth, shining, a few small punctures on 1 near declivity, others impunctate. Declivity steep, convex, shallowly bisulcate; interstriae 1 distinctly elevated, armed by a row of about seven rounded tubercles, 2 moderately impressed, slightly wider than 1 , smooth, shining, devoid of punctures, 3 convex, as high as 1 , armed as on 1, lateral areas with punctures somewhat confused. Vestiture confined to declivity, consisting of rather short, moderately coarse, sparse, interstrial setae on odd-numbered interstriae.

Female.- Similar to male except frons below upper level of eyes shallowly, broadly, transversely impressed, surface regular, not granulate, punctures moderately fine, vestiture sparse, declivital sulcus much less strongly impressed, granules on interstriae 1 and 3 minute.

Distribution.- Panama.
PaNaMA: Volcán Chiriquí, Chiriquí, 11-I-64, 1800 m , No. 407, sapling, S. L. Wood.

Notes.- The above treatment was based on the type series of 14 specimens. The host may have been Oreopanax nubigenus.

## 9. Pityophthorus mendosus Wood

Pityophthorus mendosus Wood, 1975, Great Basin Nat. 35:397 (Holotype, male; San Isidro del General, Costa Rica; Wood Coll.)

Diagnosis.- This species is distinguished from timidulus Wood by the smaller size, by the smaller pronotal punctures, by the shorter, stouter elytral bristles, and by the complete absence of tubercles on female declivital interstriae 1 and 3.

Male.- Length $1.5-1.7 \mathrm{~mm}, 2.8$ times as long as wide; color very dark brown.

Frons as in timidulus except callus at level of antennal insertion usually more strongly developed and with a small cusp at dorsomedian extremity. Pronotal punctures averaging slightly smaller than in timidulus. Elytra as in timidulus except declivital setae slightly shorter and distinctly stouter.

Female.- As in female timidulus except frons less distinctly impressed, declivital granules absent, and declivital setae shorter and stouter.

Distribution.- Costa Rica.
COSTA RICA: San Isidro del General, San José, 5-XII-63, 1000 m, No. 282, "Fosforo" leaf petioles, S. L. Wood.

Notes.- The above treatment was based on the type series of 20 specimens.

## 10. Pityophthorus degener Wood

Pityophthorus degener Wood, 1975, Great Basin Nat. 35:397 (Holotype, male; Volcán Chiriquí, Chiriquí, Panama; Wood Coll.)
Diagnosis.- This species is distinguished from the allied timidulus Wood and mendosus Wood by the much more weakly impressed male frons, by the strongly impressed elytral declivity, and by the finer pronotal punctures.

Male.- Length 1.7-2.0 mm, 2.8 times as long as wide; color very dark brown.

Frons convex, but with abrupt, irregular, shallow, transverse impressions just below upper level of eyes and just above epistoma; surface subshining, coarsely, closely punctured; almost glabrous except at epistomal margin. Pronotum and elytral disc as in timidulus and mendosus except pronotal punctures much smaller, slightly closer; elytral declivity strongly bisulcate, interstriae 1 almost as high as wide, 3 higher than 1 , each armed by a row of moderately coarse tubercles. Elytral vestiture as in timidulus.

Female.- Similar to male except median half of frons flattened below upper level of
eyes, surface smooth, with punctures rather fine, close, deep, with rather abundant, fine, moderately long hair; declivital sulcus only half as deep, interstriae 1 and 3 unarmed.

Distribution.- Panama.
PaNAMA: Volcán Chiriquí, Chiriquí, 11-I-64, 1800 m, No. 384, tree limb, S. L. Wood.

Notes.- The above treatment was based on the type series of nine specimens.

## 11. Pityophthorus punctiger (Schedl)

Neodryocoetes punctiger Schedl, 1951, Dusenia 2:108 (Holotype, sex?; Mexico; Schedl Coll.)
Diagnosis. - The placement of the unique specimen of this species is complicated by the complete concealment of the frons by the pronotum. It apparently is allied to degener Wood, but it is distinguished by the coarser, usually subasperate pronotal punctures on the dise, by the presence of minute strial setae to the elytral base, by the coarser, longer, interstrial setae on the declivity, and by the elytral declivity.

Female.- Length $1.7 \mathrm{~mm}, 2.7$ times as long as wide; color brown, basal half of pronotum darker.

Head concealed. Antennal club rather small, segment 1 rather short, sutures 1 and 2 equally marked, rather strongly arcuate.

Pronotum 1.13 times as long as wide; widest at base, sides on basal half feebly arcuate, converging slightly, weakly constricted one-third pronotum length from anterior margin, anterior margin rather narrowly rounded; summit indefinite, anterior to middle; anterior slope moderately asperate, asperities confused; disc smooth, shining punctures moderately coarse, impressed, those on anterior half of disc accompanied on lateral side by a small, subasperate elevation. Vestiture of short hair on disc and asperate areas.

Elytra 1.7 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal three-fourths, rather broadly rounded behind; striae not impressed, punctures moderately large, rather strongly impressed, mostly spaced by diameter of a puncture; interstriae one to one and one-half times as wide as striae, smooth, shining, with moderately abundant very minute points, 5 with a few punctures. Declivity confined to posterior fourth, steep; upper three-fourths
strongly, rather broadly sulcate; striae 1 and 2 shallowly, rather coarsely punctured; interstriae 1 moderately elevated, with a row of small punctures, 2 as wide as 1 , strongly, broadly impressed but deepest on median side, impunctate, smooth, shining, 3 distinctly higher than 1 , abruptly rounded, with a row of punctures. Vestiture consisting of fine, short, strial hair to base; declivity with interstrial setae except on 2; rather long, moderately abundant, these setae extend to middle of dise on 5 and in lateral areas.

Distribution.- Mexico.
Mexico: "Mexico, Flohr coll."
Notes.- The above treatmert was based on the holotype.

## 12. Pityophthorus amiculus Wood

Pityophthorus amiculus Wood, 1975, Great Basin Nat. 35:398 (Holotype, male; Guápiles, Limón, Costa Rica; Wood Coll.)
Diagnosis.- This species is distinguished from degener Wood by the absence of sexual dimorphism and by the different frons, pronotum, and other characters.

Male.- Length $1.7-1.9 \mathrm{~mm}, 2.7$ times as long as wide; color reddish brown.

Frons convex above eyes, with median line smooth, impunctate, a median callus at upper level of eyes, area below upper level of eyes broadly, shallowly, transversely impressed to epistoma; surface almost smooth, punctures moderately coarse, close, deep; almost glabrous except along epistoma.

Pronotum 1.2 times as long as wide; outline as in degener; asperate area continued slightly into lateral portion of posterior half as weak rugae; posterior areas smooth, shining, with rather numerous impressed points, punctures rather fine, moderately close, median line impunctate. Sparse setae confined to asperate area.

Elytra 1.5 times as long as wide, 1.3 times as long as pronotum; outline as in timidulus Wood; striae not impressed, punctures rather small, deep, close, rows occasionally slightly confused; interstriae smooth, shining, slightly irregular, with a few impressed lines, impressed points moderately abundant, l with obscure subgranulate punctures almost to base, others with an occasional similar puncture. Declivity steep, strongly bisulcate, sulcus commencing slightly behind middle of
elytral length; striae 1 and 2 with punctures reduced in size but clearly impressed; interstriae 1 almost as high as wide, 3 higher than 1 , each armed by a row of about eight subacute tubercles of moderate size, 2 wider than 1 , its surface ascending laterally, unarmed. Vestiture consisting of interstrial bristles on declivity, continued to middle of dise on odd-numbered interstriae; longest bristles rather slender, equal in length to twice width of an interstriae.

Female.- Similar to male in all respects.
Distribution. - Veracruz to Costa Rica.
MEXICO: Veracruz: Coatzocoalcos, 26-VI-67, 30 m , No. 103, liana, S. L. Wood. Costa RiCa: Guápiles. Limón, 22-VIII-66, 10 ( m , No. 12I, liana, S. L. Wood.

Notes.- The above treatment was based on the type series of 32 specimens.

## 13. Pityophthorus dissolutus Wood

Pityophthorus dissolutus Wood, 1975, Great Basin Nat. 35:398 (Holotype, female; 13 km SE Cartago, Cartago, Costa Rica; Wood Coll.)
Diagnosts.- This species is distinguished from explicitus Wood by the finer frontal punctures, by the finer granules on the pronotal disc, and by the shallower declivital sulcus that is armed by finer granules.

Male.- Length 1.4-1.6 mm, 2.7 times as long as wide; color dark brown.

Frons convex, a fine median tubercle on epistomal process; surface strongly reticulate, punctures rather fine, deep, spaced by diameter of a puncture or more; vestiture fine, sparse, inconspicuous.

Pronotum 1.1 times as long as wide; widest on basal half, sides feebly arcuate, subparallel, rather narrowly rounded in front; anterior margin armed by about eight moderately coarse serrations; summit at middle, indefinite; asperities rather fine, confused; posterior areas strongly reticulate, punctures rather fine, moderately close. Vestiture confined to marginal and asperate areas.

Elytra 1.6 times as long as wide, 1.5 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae 1 weakly, others not impressed, punctures fine, distinct. decreasing in size posteriorly; interstriae almost smooth, with some indistinctly impressed lines, about three times as wide as striae on basal fourth, six times as wide near declivity.

Declivity rather steep, shallowly bisulcate; striae 1 deeply impressed, punctures small, indistinct, surface ascending gradually to lateral convexity, striae 2 obscure; interstriae 1 almost as high as wide, almost smooth, with a row of fine tubercles, 2 and lateral areas shining, rather densely covered by impressed points, 3 slightly higher than 1 , similarly armed. Vestiture of minute strial hair, and, on posterior half, interstrial bristles on oddnumbered interstriae; bristles sparse, rather fine, short.

Female.- Similar to male except epistomal tubercle evidently absent and declivital impressed points reduced or absent.

Distribution.- Costa Rica to Panama.
COSTA RICA: 13 km SE Cartago. Cartago, 24-IX-63, 1500 m . No. 201, liana. S. L. Wood; Tapantí, Cartago. 24-X-63. 1300 m , No. 244. liana. S. L. Wood. PaNAMA: Volcán Chiriqui, Chiriquí, 11-I-64, 1800 m, No. 394, sapling, S. L. W'ood.

Notes.- The above treatment was based on the type series of 37 specimens.

## 14. Pityophthorus explicitus Wood

Pityophthorus explicitus Wood, 1975. Great Basin Nat. 35:399 (Holotype, female; 9 km NE Teziutlán. Puebla, Nexico; Wood Coll.)
Diagnosis.- This species is distinguished from dissolutus Wood by the coarser frontal punctures, by the larger granules on the pronotal disc, and by the deeper declivital sulcus that is armed by coarser granules.

Male.- Length $1.5-1.7 \mathrm{~mm}, 2.7$ times as long as wide; color very dark brown.

Frons as in dissolutus except punctures distinctly larger, spaced by less than diameter of a puncture. Pronotum as in dissolutus except granule on lateral margins of discal punctures distinctly larger. Elytra as in dissolutus except declivital sulcus deeper, wider, interstriae 2 not ascending laterally on lower half.

Female.- Similar to male in all respects.
Distribution.- Puebla.
NEXICO: Puebla: 9 km NE Teziutlán, 2-VII-67, 1600 m. No. 14.3, liana, S. L. Wood.

Notes.- The above treatment was based on the type series of 16 specimens.

## 15. Pityophthorus thomasi Bright

Pityophthorus thomasi Bright, 1976, Great Basin Nat.
36:443 (Holotype, female; 10 miles or 17 km SW El Salto, Durango, Mexico: Canadian Nat. Coll.)

Diagnosis.- This species is distinguished by the convex, unarmed declivity, by the minute elytral punctures, by the large number (14) of serrations on the anterior margin of the pronotum, and by the female frontal vestiture, which extends abnormally high on the vertex.

Female.- Length $1.3-1.5 \mathrm{~mm}, 2.8$ times as long as wide; color very dark brown.

Frons flattened on median three-fourths from epistoma to very high on vertex; margins subabrupt, spaced by diameters of three facets of eye from margin of eye; surface almost smooth, punctures minute; vestiture largely confined to margin, most abundant on vertex, longest setae on vertex reaching epistoma. Antennal club broadly oval; sutures 1 and 2 rather strongly procurved, 2 at middle of club.

Pronotum much as in blandus Blackman except discal punctures smaller; anterior margin armed by 14 small, subequal serrations.

Elytra 1.6 times as long as wide, 1.5 times as long as pronotum; outline about as in opaculus LeConte; striae not impressed, punctures minute, spaced within row by three diameters of a puncture; interstriae three times as wide as striae, shining, wrinkled near scutellum, obscure lines in other areas, semiobscure impressed points rather abundant, punctures mostly obsolete. Declivity broadly convex, very steep; strial punctures obsolete; interstrial punctures mostly obsolete, one or two on odd-numbered interstriae; surface obscurely shagreened. Vestiture of minute strial hair to base, $2-4$ short interstrial setae on odd-numbered interstriae on declivity.

Male. - Similar to female except frons weakly convex, punctures rather coarse, a moderate median carina from epistoma to upper level of eyes.

Distribution.- Durango.
MEXICO: Durango: 16 km W El Salto, 7 -VII-64, 2600 m , Pinus cooperi, J. B. Thomas.

Notes.- The above treatment was based on the type series of 24 specimens.

## 16. Pityophthorus digestus (LeConte)

Cryphalus digestus LeConte, 1874, Trans. Amer. Ent. Soc. 5:71 (Lectotype, sex?, Mojave Desert, California; Mus. Comp. Zool., 997, designated by Bright 1976, Coleopt. Bull. 30:185)

Pityophthorus digestus: LeConte, 1876, Proc. Amer. Philos. Soc. 15:355
Pityophthorus idoneus Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Pub. 25:55 (Holotype, female; Centerville, Idaho; U.S. Nat. Mus., 41279); Bright, 1977, Canadian Ent. 109:514. Synonymy
Pityophthorus hopkinsi Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Pub. 25:56 (Holotype, female; Ventura Co., California; U.S. Nat. Mus., 41280); Bright, 1966, Pan Pacific Ent. 42:304. Synonymy
Pityophthorus ponderosue Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Pub. 25:57 (Holotype, female; Las Vegas Hot Springs, New Mexico; U.S. Nat. Mus., 41281); Bright, 1966, Pan Pacific Ent. 42:304. Synonymy
Pityophthorus aplanatus Schedl, 1930, Canadian Ent. 62:195 (Holotype, female, Athabasca Falls, Alberta: Canadian Nat. Coll., 3132); Wood, 1978, Great Basin Nat. 38:398. Synonymy
Diagnosis.- This species is distinguished by the distinct median carina in both sexes, by the distinctive size and arrangement of elytral punctures and setae, and by other characters.

Female.- Length $1.4-2.0 \mathrm{~mm}, 2.6$ times as long as wide; color very dark brown.

Frons broadly convex, less strongly so on lower half; a conspicuous median carina from epistoma to slightly above upper level of eyes (somewhat variable), its highest point on upper half; surface shining, coarsely, closely, deeply punctured; vestiture of sparse, short, fine, inconspicuous hair. Antennal club broadly ovate, sutures weakly procurved.

Pronotum 1.02 times as long as wide; widest one-third pronotum length from base, sides on basal half moderately arcuate, feebly constricted on anterior half, rather broadly rounded in front; anterior margin armed by six to eight rather coarse, slender serrations, lateral pair notably smaller; summit at middle, a distinct impression behind it; asperities moderately abundant except near anterior margin, rather narrow, moderately coarse; posterior areas smooth, shining, rarely with areas of feeble subreticulation, punctures usually fine, sometimes irregular, some specimens from northern area rather coarse, close; median line usually impunctate. Vestiture of semirecumbent, fine hair, a seta arising from each puncture.

Elytra 1.6 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly
rounded behind; striae not impressed except 1 weakly near declivity, punctures varying from very fine (New Mexico to Alberta) to moderately coarse (Pacific Coast), usually larger and slightly confused on basal half, uniseriate and decreasing in size toward declivity; interstriae shining, often almost subrugose on basal fourth, usually with impressed lines, rarely smooth, about two to six times as wide as striae, punctures slightly smaller than those of striae, varying from regular on all interstriae (southern) to a partial reduction on even-numbered interstriae. Declivity broadly convex, rather steep; striae 1 slightly impressed, strial punctures minute, spaced by three or more diameters of a puncture; interstriae shining, almost smooth, 1 rather abruptly, weakly elevated, 2 two to three times as wide as 1 , impunctate to very sparsely, minutely punctured, 3 gradually ascending to height of 1,1 and 3 rather finely punctured, 3 armed by about four to six fine tubercles reduced in size (Wyoming) to absent (Alberta). Vestiture of rows of minute strial hair and slightly longer interstrial setae; declivital interstrial setae on 3 longer, absent on 2; discal setae on even-numbered interstriae reduced to absent when punctures obsolete.

Male- Similar to female except carina usually slightly higher.

Distribution.- British Columbia and Alberta to California and New Mexico.

CANADA: Alberta: Athabasca Falls. British Columbia: Copper Mt., Peachland. USA: Arizona: Carr Canyon in Huachuca Mts., Chiricahua Mts., Kaibab N.F., Santa Catalina Mts., Santa Rita Mts., Williams. California: Big Meadows, Elk Creek in Glen Co., Fallen Leaf Lake in Eldorado N.F., Class Mit. in Modoc Co., Harvey Valley, Hat Creek, Lake Tahoe, Los Angeles Co., Mariposa Co., Mojave Desert, Mt. Laguna, Old Station in Lassen N.F., Plumas Co., Riverside Co.. San Bernardino Co., San Diego Co., Shasta Co.. Tulare Co., Tuolumne Co., Ventura Co., Whitehorse, Yosemite N.P. Idaho: Centerville, Coeur d’Alene, Moscow Mts. Montana: Deer Lodge Co. Nevada: Little Valley in Washoe Co. New Mexico: Capitan Mts., Cloudcroft, Las Vegas Hot Springs, Meek, Sandia Mts., San Lorenzo. Oregon: Ashland, Deschutes N.F., Klamath Falls, Paisley, Salem. Utah: Alta. Washington: Elberton in Whitman Co. Wyoming: Lusk.

Hosts.-Pinus contorta, P. jeffreyi, P. ponderosa.

Biology. - Specimens were taken from branches 2-5 cm in diameter.

Notes.- The above treatment was based on the syntypes of digestus, on the holotypes of idoneus, hopkinsi, ponderosae, and aplanatus, and on 446 other specimens.

As indicated in the description, this species varies within series as well as geographically. The Alberta population differs rather sharply except that series from New Mexico to Wyoming indicate it is just the extreme end of a gradual cline. I have not recognized that population as a geographical race because of inadequate material, although there may be some evidence for doing so.

## 17. Pityophthorus festus Wood

Pityophthorus festus Wood, 1967, Great Basin Nat. 27:39 Holotype, male; 18 miles W El Salto, Durango, Mexico; Wood Coll.)
$\mathrm{D}_{\text {IAGNosis.- This species }}$ is distinguished from digestus (LeConte) by the smaller average size, by the larger, more regular strial punctures, by the near absence of interstrial punctures, and by other characters cited below.

Female.- Length $1.3-1.6 \mathrm{~mm}, 2.6$ times as long as wide; color very dark brown.

Frons as in digestus except lower half more distinctly flattened and carina often reduced near epistoma.

Pronotum as in digestus except serrations on anterior margin smaller, posterior areas almost always subreticulate in specimens from southern part of range, shining, punctures uniformly rather coarse.

Elytra similar to digestus except smooth to base, strial punctures more nearly in rows to base, moderately coarse to declivity; interstriae less than twice as wide as striae, almost entirely impunctate; declivital striae 2 more coarsely punctured, interstriae 2 more distinctly impressed, only twice as wide as 1,3 with small granules more closely spaced on middle half; interstrial setae absent on evennumbered interstriae, sparse on disc on oddnumbered interstriae, regular on declivity and uniformly as long or longer than those on 3 of digestus.

Male.- Similar to female except serrations on anterior margin of pronotum slightly larger, elytral punctures slightly more confused.

Distribution.- Arizona to Jalisco and Chiapas.

USA: Arizona: Bear Canyon, Santa Catalina Mts., Chiricahua Mts. MEXICO: Chiapas: Ocosingo, Teopisca, Yerba Buena. Chihuahua: 37 km S Creel. Durango: $5,29,35 \mathrm{~km}$ W El Salto, Palmito. Jalisco: 23 km NW Guadalajara. Mexico: Nepantla, Ocoyoacac. Veracruz: Las Vigas.

Hosts.-Pinus ayacahuite, P. leiophylla, P. spp.

Biology.-Specimens infested the phloem of small branches.

Notes.- The above treatment was based on the type series of 19 specimens and on 166 other specimens. The pronotal disc is smooth in specimens from Durango to Arizona, but partly reticulate in those from southern areas.

## 18. Pityophthorus puberulus (LeConte)

Cryphahus puberulus LeConte, 1868, Trans. Amer. Ent. Soc. $2: 157$ (Holotype, sex?; District of Columbia; Mus. Comp. Zool., 998)
Pityophthorus pubcrulus: LeConte, 1876, Proc. Amer. Philos. Soc. 15:354
Pityophthorus infans Eichhoff, 1872, Berliner Ent. Zeitschr. 15: I35 (Holotype, sex?; Amer. Bor. (Civitat. unit.): (Apparently lost with Hamburg Mus.); Bright. 1978, Great Basin Nat. 38:72 (Neotype, female; Syracuse, New York; U.S. Nat. Mus.): Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Pub. 25:49. Synonymy
Diagnosis.- This species is distinguished from opaculus LeConte and allied species by the partly to entirely reticulate pronotal disc and by the more crowded, more nearly confused discal interstrial punctures.

Female.- Length $1.2-1.5 \mathrm{~mm}, 2.5$ times as long as wide; color brown.

Frons broadly convex, surface shining, rather closely punctured; vestiture sparse, inconspicuous; occasional specimens with a weak median carina.

Pronotum 1.05 times as long as wide; widest near base, sides rather weakly arcuate on basal half, distinctly constricted in front of middle; anterior margin rather narrowly rounded, armed by about six teeth, median ones usually slightly larger; posterior areas partly to entirely reticulate, punctures moderately coarse, rather deep, without granules behind summit. Vestiture of fine, semirecumbent hair.

Elytra 1.6 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly
rounded behind; striae not impressed, punctures rather fine, in rows on about posterior third of disc, moderately to strongly confused toward base; interstriae shining, almost smooth, punctures moderately abundant, similar to and confused with those of striae. Declivity convex, moderately steep; sutural interstriae distinctly elevated, 2 slightly impressed, lateral convexities as high as suture, broadly rounded, punctures minute but visible; granules on interstriae 3 very minute. Vestiture of moderately abundant, rather short hair.

Male.-Similar to female in all respects.
Distribution.- Minnesota and Nova Scotia to Kansas and Virginia.

CaNADA: Nova Scotia, New Brunswick, Ontario, Quebec. USA: District of Columbia, Indiana, Kansas, Kentucky, Maine, Massachusetts, Michigan, Minnesota, New Hampshire, New Jersey, New York, North Carolina, Ohio, Pennsylvania, Rhode Island, Virginia, West Virginia, Wisconsin.

Hosts.- Abies balsamea, Picea spp., Pinus banksiana, P. resinosa, P. silvestris, P. strobus.

Biology.- This species breeds in small twigs of its hosts.

Notes.- The above treatment was based on the holotype of puberulus and on 981 other specimens.

## 19. Pityophthorus abstrusus Bright

Pityophthorus abstrusus Bright, 1976, Great Basin Nat. 36:427 (Holotype, female: 25 miles or 40 km W Orizaba, Veracruz, Mexico; Canadian Nat. Coll., 15071)

Diagnosis.- This species is distinguished by the coarse strial punctures on both disc and declivity, by the short female frontal vestiture, and by the short, subdentate male frontal carina.

Female.- Length $1.5-1.6 \mathrm{~mm}, 2.7$ times as long as wide; color very dark brown.

Frons very broadly convex, punctures coarse, close, uniformly distributed; vestiture rather inconspicuous, mostly short, about a dozen setae of moderate length.

Pronotum and elytra as in petillus Schedl except pronotal disc smooth, shining; elytra with strial punctures coarse, almost as wide as interstriae, those on declivity about twothirds as long as those on disc.

Male.- Similar to female except frons with a short, high, subdentate median carina on lower half.

## Distribution.- Veracruz.

MEXICO: Veracruz: 40 km W Orizaba, 29-IV-69, Pinus, D. E. Bright.

Notes.- The above treatment was based on the holotype and allotype. The paratypes, four from Durango, are not of this species.

## 20. Pityophthorus punctifrons Bright

Pityophthorus punctifrons Bright, 1966, Pan Pacific Ent. 42:298 (Holotype, female; Frazier Park, Kern Co., California; California Acad. Sci.)
Diagnosis.- This species is distinguished from modicus Blackman by the smaller size, by the very different frons in both sexes, and by the different declivity as described below.

Female.- Length 1.4-1.8 mm, 2.6 times as long as wide; color very dark brown.

Frons broadly convex; surface smooth, shining, punctures rather coarse, moderately close, uniformly distributed; vestiture short, sparse, inconspicuous.

Pronotum about as in modicus except with $8-12$ serrations on anterior margin, only slightly larger in median area.

Elytra as in modicus except punctures on declivital striae 2 minute, distinct, not replaced by granules, interstriae 2 very feebly impressed on median side (much less than in modicus), 3 with minute punctures, granules entirely absent; vestiture minute but very slightly longer than in modicus.

Male. - Similar to female except frons more distinctly convex, more coarsely punctured, usually with an obscure, low median carina indicated.

Distribution.-California to New Mexico.

USA: California: Frazier Park, 9-IN-65, Pinus monophylla, D. E. Bright; Mt. Laguna, 19-III-41, Hopk. 32525B, P. quadrifolia, D. DeLeon; Wrightwood, 21-X41. P. monophylla, J. M. Miller. New Mexico: Santa Fe, Hopk. US 37219-F, P. edulis.

Hosts.- Pinus edulis, P. monophylla, P. quadrifolia.

Notes.- The above treatment was based on 17 paratypes.

## 21. Pityophthorus modicus Blackman

Pityophthorus modicus Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Pub. 25:94 (Holotype, female; Las Vegas H.S., New Mexico; U.S. National Mus., 41299)
Pityophthorus natus Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Pub. 25:95 (Holotype, female; Morgan Hill, California: U.S. National

Mus., 41300): Bright, 1966. Pan Pacific Ent. 42:304. Synonymy
Diagnosis.- Not closely related to any known species except punctifrons Bright; male frons without a carina, female frons as in tuberculatus; elytral dise usually glabrous (due to abrasion). Declivital striae 2 and 3 each with a row of minute granules.

Female.- Length $1.5-1.8 \mathrm{~mm}, 2.6$ times as long as wide; color very dark brown.

Frons plano-concave from eye to eye from epistoma to well above eyes, central area smooth, shining, impunctate (similar to tuberculatus Eichhoff), lateral and upper margins with a row of coarse punctures; these punctures bearing a marginal row of long hair.

Pronotum 1.1 times as long as wide; widest on feebly arcuate basal half; anterior margin rather narrowly rounded, armed by about eight serrations, median pair much larger; dise smooth, shining, punctures moderately coarse, rather close. Vestiture of fine, short, recumbent hair.

Elytra 1.6 times as long as wide, 1.5 times as long as pronotum; outline about as in pubcrulus; striae not impressed, except 1 slightly near declivity, punctures in rows, moderately coarse, rather deep, close; interstriae smooth, shining, 1, 3, and 5 each with about three widely spaced punctures. Declivity convex, steep; strial punctures reduced in size (usually obsolete in California specimens), shallow, those on 2 and 3 replaced by minute granules, interstriae 1 and 3 each with a row of similar granules; interstriae 2 wider than 1 or 3, smooth, impunctate, shallowly, rather broadly impressed. Vestiture of minute strial hair and an occasional similar interstrial hair; abraded on dise in most specimens.

Male.-Similar to female except frons broadly convex, coarsely, deeply punctured, brightly shining; a feeble, irregular, median carina present in one series from New Mexico, entirely absent in others.

Distribution.- California and Utah to Baja California and Durango.

USA: Arizona: Chiricahua Mts., Jacob's Lake, Jerome, Parker Canyon in Cochise Co., Sweetwater in Apache Co., Williams. California: Big Bear in San Bernardino Co., Frazier Park, Morgan Hill, Mt. Hamilton, Pine Mt. Summit in Los Padres N.F., Valyermo. Wrightwood in San Bernardino Co. Nevada: Baker, Steamboat in

Washoe Co. New Mexico: Lake Roberts, Sandia Mts., San Lorenzo, Silver City. Utah: Arches Nat. Mon., Orderville, Zion N.P. MEXICO: Chihuahua: La Pinta. Durango: $30 \mathrm{~km} W$ Durango.

Hosts.-Pinus cembroides, P. edulis, P. monophylla, P. sabiniana.

Notes.- The above treatment was based on 223 specimens. Bright (1966:304) cites the occurrence of this species in Baja California.

## 22. Pityophthorus minus Bright

Pityophthorus minus Bright. 1976, Great Basin Nat. 36: 437 (Holotype, female; Hannagan Camp, Greenlee Co., Arizona; Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from segnis Blackman by the minute elytral hair and by the complete absence of granules on declivital interstriae 1 and 3 .

Female.- Length $1.8 \mathrm{~mm}, 2.9$ times as long as wide; color brown.

As in segnis except as noted in the diagnosis.

Male.-Similar to female except frons as in male segnis.

Distribution.- Arizona.
USA: Arizona: Hamnagan Camp, Greenlee Co., 12-VII-68, D. E. Bright.

Notes.- The above treatment was based on the holotype and allotype.

## 23. Pityophthorus segnis Blackman

Pityophthorus segnis Blackman, 1928, New York St. Coll. For., Syracuse. Tech. Pub. 25:52 (Holotype, female; Santa Catalina Mts., Arizona; U.S. Nat. Mus. 41278)
Diagnosis.- This species is distinguished from opaculus LeConte by the dull, subreticulate to reticulate surfaces of the pronotum and elytra and by the coarse, erect, sparse setae on the odd-numbered declivital interstriae. It intergrades with subopacus Blackman in Durango.

Female.- Length $1.6-1.9 \mathrm{~mm}, 2.9$ times as long as wide; color very dark brown.

Frons as in opaculus except with fewer than a dozen setae in lateral areas much longer. Pronotum as in opaculus except surface dull, at least partly reticulate on disc (varying from shining to strongly reticulate in some series), punctures usually distinctly smaller. Elytra as in opaculus except surface dull, punctures larger but less sharply impressed, odd-numbered declivital interstriae
each with a sparse row of coarse, erect setae, each equal in length to one or two times width of an interstriae.

Male.- Similar to female except frons less clearly flattened and without long setae, a long, weak, median carina usually present.

Distribution.-Arizona and New Mexico to Durango.
USA: Arizona: Bear Wallow in Santa Catalina Mts., 11-VI-69, 2600 m , No. 92, Pinus strobiformis, S. L. Wood, 31-VII-74 by D. E. Bright, and 19-VIII-07, Hopk. $5613 \mathrm{a}, \mathrm{J}$ J. L. Webb; Sabino Canyon in Pima Co.; San Francisco Mts.; Santa Rita Mts. New Mexico: Sacramento Mts., Hopk. 5752, P. strobiformis, J. L. Webb. MEXICO: Durango: 70 km W Durango.
Hosts.-Pinus strobiformis, $\quad P$. engelmannii.

Biology.- Specimens were taken from small twigs.

Notes. - The above treatment was based on the holotype and on 364 other specimens.
his species intergrades with subopacus to a remarkable degree, but it is distinguished by the slightly impressed, shining female frons with punctures indistinct (more strongly convex, reticulate, and clearly punctured in subopacus), there is also a slight difference in the punctures near the elytral apex.

## 24. Pityophthorus culminicolae Bright

Pityophthorus culminocolae Bright, 1977, Canadian Ent. 109:524 (Holotype, female; Cerro Potosí, Nuevo León; Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from absonus Blackman by the much more strongly impressed declivial sulcus, by the absence of long hair on the female frons, by the shorter, less abundant elytral vestiture, and by other characters.

Female.- Length $1.5-1.9 \mathrm{~mm}, 2.8$ times as long as wide; color very dark brown.

Frons somewhat flattened on median twothirds of area below upper level of eyes, convex elsewhere; surface smooth, shining, rather coarsely, not closely punctured, a very feeble median carina indicated in most specimens.

Pronotum as in absonus except vestiture much less abundant.

Elytra as in absonus except disc smoother, strial punctures in more regular, definite rows, declivity much more deeply sulcate, with lateral convexities conspicuously higher than suture, punctures more nearly obsolete.

Male.- Similar to female except frons more strongly convex, a distinct, low, median carina occupying at least two-thirds distance between epistoma and upper level of eyes.

Distribution.- Nuevo León.
MEXICO: Nuevo León: Cerro Potosí, 4-V-71, D. E. Bright and 19-III-74, Hopk. 58606-B. Pinus culminacola. M. M. Furniss.

Notes. - The above treatment was based on the type series of 135 specimens.

## 25. Pityophthorus absonus Blackman

Pityophthorus absonus Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Pul). 25:35 (Holotype, female; Mineral King, California; U.S. Nat. Mus., 41269)

Pityophthorus demissus Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Pub. $25: 74$ (Holotype, female: Glacier National Park, Montana; U.S. Nat. Mus., 41289); Bright, 1977, Canadian Ent. 109:513. Synonymy
Pityophthorus inyoensis Bright, 1971, Pan Pacific Ent. 47:65 (Holotype, female; 1 mile S Onion Valley, Inyo Co., California; Canadian Nat. Coll.; Bright. 1977, Canadian Ent. 109:513. Synonymy
Diagnosis.- This species is distinguished from opaculus LeConte by the slightly larger size, by the absence of tubercles behind the pronotal summit, and by the different female frons.

Female.- Length 1.6-1.8 mm, 2.8 times as long as wide; color very dark brown.

Frons broadly flattened to well above eyes, plano-concave on about central half; surface shining, coarsely punctured, punctures somewhat smaller and less dense on central area of lower half; a sparse brush of long hair extending to center, marginal setae longer and more numerous.

Pronotum 1.1 times as long as wide; outline about as in puberulus (LeConte); anterior margin armed by six teeth (usually irregular); posterior areas smooth, shining, punctures small, usually of irregular size at least near posterior margin, punctures immediately behind summit never granulate. Vestiture of fine, rather short, semirecumbent hair.

Elytra 1.7 times as long as wide, 1.8 times as long as pronotum; outline about as in $p u$ berulus; striae not impressed, punctures very fine, in rows on posterior half of dise, moderately to strongly confused toward base; interstriae smooth and shining, with a few lines on posterior half, moderately to strongly
wrinkled on basal third, punctures mostly confined to basal half. Declivity convex, steep; strial punctures very minute, but visible; interstriae 1 distinctly elevated, 2 shallowly impressed, wider than 1 or 3 , impunctate, almost smooth, 3 with a row of fine punctures (occasionally some of them feebly granulate). Vestiture of fine, short strial and interstrial hair on disc and declivity.

Male.- Similar to female except frons broadly convex below upper level of eyes, more strongly convex above, surface more irregular, more finely, sparsely punctured, a strong, rather short, median carina on middle half of area between epistomal margin and upper level of eyes, vestiture spars ᄅ, inconspicuous; teeth on anterior margin of pronotum larger, regular.

Distribution.- British Columbia and Alberta to California and Colorado.

CANADA: Alberta: Banff, Blairemore. British Columbia: Coal Creek in Kootenay District, Creston, Lorna, Nahun, Rossland. USA: California: Hat Creek, Lake Tenava, Mineral King, Mt. Lassen, Robinson Lake (Onion Valley), Yosemite N.P., Westgard Pass in lnvo Co. Colorado: Cameron Pass, Evergreen, Gould. Montana: Glacier N.P. Nevada: Wheeler Peak. Utah: Logan Canyon, Park City, Scofield.

Hosts.- Abies lasiocarpa, Pinus albicaulis, P. aristata, P. balfouriana, P. contorta, P. monticola.

Biology.- This species breeds in small branches and in shaded out seedlings.

Notes. - The above treatment was based on 176 specimens. The holotypes of absonus, demissus, and inyoensis were examined.

## 26. Pityophthorus opaculus LeConte

Pityophthorus opaculus LeConte, 1878, Proc. Amer. Philos. Soc. 17:623 (Holotype, female: Darquette, Michigan; Mus. Comp. Zool., 1290)
Pityophthorus abietis Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Pub. 25:49 (Holotype, female; Silver Lake, Utah; U.S. Nat. Mus., 41275); Bright, 1977, Canadian Ent. 109:517. Synonymy
Pityophthorus albertensis Blackman. 1928. New York St. Coll. For., Syracuse, Tech. Pub. 25:50 (Holotype, female; Banff Sp., Alb., presumably Banff Springs, Alberta; U.S. Nat. Mus., 41276); Bright, 1977, Canadian Ent. 109:517. Synonymy
Pityophthorus exiguus Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Pub. 25:51 (Holotype, female; Ft. Garland, Colorado; U.S. Nat. Mus., 41277); Bright, 1977, Canadian Ent. 109:517. Synonymy

P'ityophehorus pysmacus sched. 1931. Camadian Ent.
 Canadian Nat. Coll. 3169): Wood. 1957. Camadian Ent. S9:401. Synomymy
Dagnosis. - This species is distinguished from absonus Blackman by the smaller size. by the presence of minute gramules on the pronotal dise, and by the very different female frons.

Female.- Length 1.1-1.6 mm, 2.6-2.9 times as long as wide: color brown to dark brown. Specimens from eastem part of range distinctly stouter than those from west.

Frons convex, a weak (variable) transserse impression on lower half: surface shining, rather coarsely, uniformly punctured: vestiture variable: glabrous to inconspicuously pubescent. Females from Colorado and Utah very different, see Notes below.

Pronotum 1.05 times as long as wide; outline about as in puberulus LeConte; anterior margin armed by six teeth: posterior areas shining, rather coarsely, deeply punctured. punctures on dise each with a minute granule on posterior rim. Vestiture of fine, short, semirecumbent hair.

Elytra 1.7-1.8 times as long as wide. 1.8 times as long as pronotum: outline about as in puberulus: striae not impressed, rows of minute punctures extend to base: interstriae minutely irregular, not smooth, wrinkled on basal fourth. Deelivity as in absonus.

Male- Similar to female, frons as deseribed above.

Distribution- Alaska and Nova Scotia to California and West Virginia.

DLASKA: Farbanks. Hope CANDDA: Aherta. Britwh Cohmbia. Manitoba, New Brmowick. Newfomdland. Northwes Territories. Nova Solia, Ontario. Queber, Saskatchewan, Yokon, USA: Arizona, California. Colorado. Kdoho, Mane, Michigan, Mimesota. Nerada, Now llamphire. New Mexico, New York. Pemmswamia, Sonth Dakota. L'tah, Weet Virginia, Wyoming.

Hosts.-Abics balsamea, A. concolor, A. lasiocarpa. Picea cngelmamii, P. glauca, P. pungens, Pinus syluestris.

Notes. - The above treatment was based on the holotypes of opaculus. pygmacus, and exiguus and on 881 other specimens.

The only two females at hand from Utah and Blackman's females of cxiguus have the frons almost flat and rather abruptly angled at the margin near the eve, and the surface is finely, rather sparsely punctured and ornamented by moderately abundant, rather long
hair. Specimens from Nevada, South Dakota, and northeastern Wyoming do not share this character. If the population from Utah and Colorado consistently exhibits this character, then exiguus should be given subspecific rank.

## 27. Pityophthorus pellitus Schedl

Iityophthorus pellitus Schedl, 1955, Zeitsch. angew. Ent. 35:23 (Lectotype, female: Quezaltenango, Guatemala: Schedl Coll., designated by Bright. 1976:156
Dagnosis. - This species is distinguished from deletus LeConte by the reticulate pronotum, by the coarser elytral punctures, and by the differences on the frons of both sexes.

Female- Length $1.3-1.5 \mathrm{~mm}, ~ 2.6$ times as long as wide: color dark brown.

Frons feebly convex, shining, finely, rather closely punctured, ormamented by sparse. rather short hair, longest setae equal to less than one-fifth distance between eves.

Pronotum 1.0 times as long as wide; similar to deletus but more broadly romeded in front: anterior margin armed by four teeth; posterior areas reticulate, punctures rather fine. moderately close. Vestiture of fine. semirecumbent hair.

Elytra 1.7 times as long as wide. 1.8 times as long as pronotum: outline about as in pubcrulus LeConte: striae 1 feebly, others not impressed, punctures moderately coarse. rows slightly confused on basal half; interstriae smooth, about two to three times as wide as striae, punctures sparse. Declivity convex, steep; punctures greatly reduced: essentially as in puberulus.

Male. - Similar to female except frons more strongly convex, more coarsely punctured, armed by a fine, low, median carina from epistoma to upper level of eves, vestiture shorter.

Distribution.- Hidalgo to Guatemala.
MESICO: Chiapas: 9 km SE San Cristólal, Pinus. D. E. Bright. Hidalgo: 6 km E Zacatlan. I2-V1-67. 2500 m . No. 19. Pimus. Oavaca: 154 km 5 Oanaca. P. lausonii. D. E. Bright: Suchistepec. P. oocorpa, D. E. Bright. Puebla:
 Nochixtlán. 17-\1-67. Pinus. Querétaro: Pinal del Amoles. Pinus greggi, D. E. Bright. GUATEMAL.A: Guatemala City, 30-V-64, 1300 m . Pinus: Quezaltenango. 26-1-64, P. pscudostrobus: Totonicipan. 25-1-64. 1600 m, P. psetudostrobus: San Cristobal, 2S-64. 2300 m. P. pseudostrobus; Volcán de Agna, 19-V-64, 1000 m . $r$. pseudostrohus: all were collected by me.

Hosts.- Pinus greggii, P. lausonii, P. oocarma, P. pseudostrohus, $P$. spp.

Biology. - Specimens were taken from small branches.

Notes. - The above treatment was based on Schedl's syntypes and on 51 other specimens.

## 28. Pityophthorus mormon Bright

Pityophthorus mormon Bright, 1977, Canadian Ent. 109:52s (Holotype, frmate: Parowan Canyon. Utali, Wiond Coll.
Diagnosis. - This species is distinguished from others in the digestus group by the feebly concave female frons, which bears a tuft of long hair, by the distinct tubercles on declivital interstriae 1 and 3 , and by other characters.

Female.-Length $1.7-1.9 \mathrm{~mm}, 2.7$ times as long as wide; color dark brown.

Frons very broadly, feebly concave from near epistoma to above upper level of eyes; surface shining, closely, rather finely, imiformly punctured; margins onnamented by rather abundant, very long hair.

Pronotum about as in absonus except punctures on posterior areas much coarser, closer; anterior margin with four to eight serrations.

Elytra as in absonus Blackman except declivity more broadly impressed, interstriae 1 and 3 each with a row of fine gramules, declivital vestiture slightly longer.

Male- Similar to female except frons distinctly convex, shining, vestiture inconspicnous, a sharply elevated median carina from epistoma to upper level of eyes, highest just below its middle.

Distribution.-California to Arizona and Utah.

USA: Arizona: Agassiz l'eak, San Franciseo Mls., 16-VIII-fo, Pinus aristata, D. E. Brishl. California: Blancos Corral at White Mts., Mono Co., 23-V1-53, 3300 m, $P^{\prime}$. aristata, J. W. NacSwaine: Utah: Convulsion, Fishlake N.F., 9-VI-60, P. flexilis, S. L. Wood; Parowan Canyon, Iron Co., 20-VI-60), P. aristata, P. flexilis, S. L. Wiood; Pin Hollow, Fishlake N.F., G VI-60, P. flexilis, S. I.. Wood.

Hosts. - Pinus aristata, P. flexilis.
Brology.-Specimens were taken from small branches.

Notes.- The above treatment was based on the type series of 56 specimens and on one other specimen.

## 29. Pityophthorus woodi Bright

J'ityophthorus woodi Bright, 197T, Camadian Ent. 109.531 (Holotype, lamate: 11.5 hm or 7 mi W Kingston, New Mexieo; Canadian Nat Coll.)
Dragnosis. - This species is distinguished by the small size, by the total absence of punctures and gramules on the declivity, by the feebly concave female frons, and by other characters.

Female.- Length 1.1-1.3 mm, 2.6 times as long as wide; color brown.

Frons feebly concave on median two-thirds below upper level of eves; surface smooth, shining, vestiture short, inconspicuous.

Pronotum about as in dolus Wood except anterior slope with fewer, higher asperities, anterior margin armed by two to four serrations, median pair much larger, posterior areas smooth, shining, rather coarsely punctured.

Elytra much as in opaculus; strial punctures small, not close, in semidefinite rows; interstriae smooth, shining, punctures sparse, similar to those of striae. Declivity steep, convex, almost smooth, completely without punctures or granules. Vestiture of mimute strial and slightly longer, sparse interstrial setac; absent on declivity.

Male - Similar to female except frons weakly convex, coarsely pmetured, with a weak median carina from epistoma to upper level of eves.

Distribution. - New Mexico.
YSt: New Mexico: 11 km or 7 miles 16 Kingtom, 5 (1-69), 2200) m. No, 5x. Pinus adulis twiss, S. I. Werod.

Notes. - The above treatment was based on the type series of 12 specimens.

## 30. Pityophthorus dolus Wood

Pityophthorus dolus Woodl, IGfit, Creal Basin Nal. 24 fi5 Holotype, female; MeClourl, Siskiyon Co., Califorma; Weod Coll.
Diaginosis.- Declivital punctures and granules obsolete, pronotal and elytral punctures on disc very small, male frons with a very low, fine carina from epistoma to upper level of eyes, female frons broadly flattened, coarsely punctured, and ornamented by moderately abundant long hair.

Female.- Length 1.3-1.5 mm, 2.8 times as long as wide; color very dark brown.

Frons flattened from eye to eye, gradually, transversely impressed above epistoma;
surface rather sparsely punctured, punctures distinctly larger than in deletus LeConte; vestiture as in deletus.
Pronotum very slightly longer than wide; similar to but more broadly rounded in front than in deletus; anterior margin bearing four serrations, median pair rather widely set but with their bases almost touching; posterior area subshining, with minute points, punctures rather large, deep, close; vestiture evident only at sides.

Elytra 1.8 times as long as wide; sides almost straight and subparallel on basal twothirds, rather narrowly rounded behind; striae not impressed, punctures small, in irregular rows; interstriae almost smooth, subshining, with a few scattered punctures equal in size to those of striae. Declivity moderately steep, convex; striae 1 strongly impressed, punctures only slightly smaller than on disc, other striae not impressed but punctures strongly reduced; interstriae 1 abruptly, slightly elevated, unarmed, 2 and 3 smooth, 3 with minute punctures. Vestiture consisting of minute strial and interstrial hair, sometimes longer at sides.

Male. - Similar to female except frons weakly convex, with a fine, low, median carina on lower half; punctures of pronotum and elytra smaller; punctures on declivity greatly reduced, scarcely visible.

Distribution.- California.
USA: California: Bass Lake; Idyllwild; McCloud, 14-VI-61, Pinus ponderosa, S. L. Wood.

Hosts.- Pinus lambertiana, P. ponderosa.
Brology.- Specimens were taken from small twigs.

Notes.- The above treatment was based on the type series of 26 specimens. Other records are cited by Bright (1973:107).

## 31. Pityophthorus clivus Bright

Pityophthorus clicus Bright, 1977, Canadian Ent. 109:522 (Holotype, female; Cerro Potosí, Nuevo León, Mexico; Canadian Nat. Coll.)
Diagnosis.- The position of this species is uncertain; it could be easily placed in any one of at least three species groups. It is distinguished from deletus LeConte by the more gradual declivity, with minute tubercles on interstriae 1 and 3 , by the larger strial punctures, and by the different frons in both sexes.

Female.- Length $1.6-1.7 \mathrm{~mm}, 2.7$ times as long as wide; color dark brown.

Frons broadly plano-convex from epistoma to slightly above upper level of eyes; surface smooth, shining, sparsely, rather finely punctured; vestiture largely confined to margins, consisting of a moderately closely set row of very long hair.

Pronotum as in digestus LeConte.
Elytral outline as in digestus; striae not impressed except 1 on posterior third of disc, punctures fine, in definite rows on at least posterior half; smooth, shining, slightly wrinkled and with confused punctures toward scutellum; interstriae about three times as wide as striae, even-numbered impunctate, others sparsely punctured. Declivity moderately steep, convex, shallowly sulcate; striae 1 and 2 with punctures very fine, distinct; interstriae 1 distinctly elevated, with a row of minute granules, 2 at least twice as wide as 1 , smooth, shining, 3 rounded, as high as 1 , with several minute granules. Vestiture of minute strial hair, length of each up to twice diameter of a puncture, sparse interstrial setae similar to those of striae.

Male.- Similar to female except frons moderately convex, more coarsely punctured, moderate carina extending from epistomal margin two-thirds distance to upper level of eyes, vestiture short, inconspicuous.

Distribution.- Nuevo León.
MEXICO: Nuevo León: Cerro Potosí, 4-V-71, Pinus strobiformis, D. E. Bright.

Notes.- The above treatment was based on the type series of 30 specimens.

## 32. Pityophthorus deletus LeConte

Pityophthorus deletus LeConte, 1879, U.S. Dept. Interior, Geol., Geogr. Surv. Bull. 5:519 (Lectotype, sex?; Veta Pass, Colorado; Mus. Comp. Zool. designated by Bright, 1976, Coleopt. Bull. 30:185)
Pityophthorus inquietus Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Pub. 25:46 (Holotype, female; Las Vegas Hot Springs, New Mexico; U.S. Nat. Mus., 41272); Wood, 1977, Great Basin Nat. 37:387. Synonymy
Pityophthorus monophyllae Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Pub. 25:47 (Holotype, female; Argus Mts., California; U.S. Nat. Mus., 41273); Wood, 1977, Great Basin Nat. 37:387. Synonymy
Pityophthorus socius Blackman, 1928, New York Coll. For., Syracuse, Tech. Pub. 25:48 (Holotype, female: Argus Mts.. California; U.S. Nat. Mus., 41274); Bright. 1971, Pan Pacific Ent. 47:67. Synonymy

Pityophthorus piceus Bright, 1966, Pan Pacific Ent. 42:297 (Holotype, female; Mount Pinos, Ventura Co., California; Califomia Acad. Sci.); Bright, 1971, Pan Pacific Ent. 47:67. Synonymy
Pityophthorus praealtus Bright, 1966, Pan Pacific Ent. 42:303 (Holotype, female; Mt. Shasta Ski Area. Siskiyou Co., California; California Acad. Sci.); Wood, 1977, Great Basin Nat. 37:387. Synonymy Pityophthorus brucki Bright, 1971, Pan Pacific Ent. 47:63 (Holotype, female; San Bernardino, California; Ohio State University); Wood, 1977, Great Basin Nat. 37:388. Synonymy
Diagnosis.- This variable species is most likely to be confused with opaculus LeConte. It is distinguished from opaculus by the slightly larger average size, by the presence of only two to four teeth on the anterior margin of the pronotum, by the absence of minute granules on the posterior margins of the punctures on the pronotal disc, and by frontal characters in both sexes.

Female.- Length 1.3-1.7 mm, 2.6-2.8 times as long as wide; color brown to very dark brown.

Frons variable, plano-convex to planoconcave from epistoma to upper level of eyes; convex above; surface shining, rather coarsely punctured in lateral areas, rather finely to very finely punctured in central area of lower half; vestiture from fine, short, sparse to fine, very long, moderately abundant (in Utah and California both extremes may occur in same series).

Pronotum as in opaculus except anterior margin armed by two to four teeth (rarely six), punctures on posterior areas usually larger, deeper, more sharply defined, never with granules on posterior rims on disc.

Elytra as in opaculus (equally variable).
Male.- Similar to female except frons flattened on a smaller area, subconvex, more coarsely punctured, armed by a small, short carina or tubercle (usually lower, shorter, and less well developed than in opaculus).

Distribution.- California and Durango to South Dakota and New Mexico.

USA: Arizona: Bright Angel Point, Carr Canyon, Kaibab N.F., Santa Catalina Mts. California: Argus Mts., Juniper Hills near Valyermo, Mt. Pinos in Ventura Co., Sugar Loaf Mt. in San Bernardino Co. Colorado: Colorado N.F., Estes Park, Gould, La Veta Pass, Poudre Canyon. Nevada: Baker. New Mexico: Kingston, La Flacita, Lake Roberts, Las Vegas, Hot Springs, Meek, Nogal Lake, Sandia Mts., Santa Fe. South Dakota: Cheyenne Crossing, Custer. Utah: Beaver, La Sal, Logan Canyon, McKee Draw in Ashley N.F., Gooseberry in Fishlake
N.F., Moab, Monticello, Mt. Carmel. Wyoming: Buffalo. MEXICO: Durango: 35 km W Durango.

Hosts.-Pinus cembroides, P. edulis, P. monophylla, less common in $P$. flexilis, $P$. ponderosa, P. strobiformis, Pseudotsuga menzeisii (accidental?).

Biology.- This species breeds in small branches.

Notes.- The above treatment was based on 2 syntypes and 8 topotypes of deletus, on the holotypes of inquietus, monophyllae, and socius, on 3 paratypes of brucki, on 2 paratypes of piceus, on 2 paratypes of praealtus, and on 439 other specimens.

Over much of its range this species might be subdivided into races based on the presence or absence of a brush of long frontal hair in the female and variability in the male frontal carina. The female frontal hair is usually short in most specimens from Arizona, New Mexico, Colorado, South Dakota, Wyoming, and southeastern Utah (deletus s. str.). It is usually long in specimens from northern Mexico, California, and northern and western Utah. Nevertheless, series from the Argus Mts., California, and Beaver, Utah, contain both extremes in about equal numbers. Occasional or frequent intermediates may occur in any area. The male carina is weak to absent in the southeastern parts of the range and stronger in the northwest. Until a great deal more is known of the range and variability of this species, geographical races should not be recognized. It is possible that a complex of several species is concealed in this variability in addition to geographical races, but, until a comprehensive analysis of this variability is made, it is considered best to treat all forms under the name deletus.

## 33. Pityophthorus trepidus Bright

Pityophthorus trepidus Bright, 1978, Great Basin Nat. 38:83 (Holotype, female; Ukiah, California; U.S. Nat. Mus.)
Diagnosis.- This species is distinguished from pinguus Blackman by the smaller size, by the more narrowly impressed striae 2 , with the lateral areas more evenly convex, by the complete absence of granules on declivital interstriae 2 , and by the very minute interstrial setae.

Female.- Length $1.5-1.9 \mathrm{~mm}, 2.6$ times as long as wide; color very dark brown.

As in pinguus except as noted in diagnosis. Male.- Similar to female.
Distribution.- California.
USA: California: Ukiah, Hopk. US 20976, Pinus radiata.

Notes. - The above treatment was based on the type series of 11 specimens. Since Pinus radiata does not occur naturally at Ukiah, the specimens must have come from an unnatural situation or from a misidentified host.

## 34. Pityophthorus keeni (Blackman)

Myeloborus keeni Blackman, 1928, New York St. Coll. For., Syracuse. Tech. Pul. 25:19 (Holotype, sex?: Jacumba, California; U.S. Nat. Mus., 41260)
Diagnosis.- This species is distinguished from pinguus Blackman by the more evenly convex elytral declivity, by the row of punctures or granules on declivital interstriae 2, and by the much finer punctures on the frons.

Female.- Length $1.8-2.2 \mathrm{~mm}, 2.7$ times as long as wide; color very dark brown.

Female as in pinguus except frons much more finely punctured (interspaces mostly two or more times diameter of a puncture) and elytral declivity evenly convex, interstriae 2 less distinctly impressed, with a sparse row of fine, setiferous punctures (one or two punctures sometimes present at apex in pinguus).

Male- Similar to female.
Distribution.- California to Colorado.
USA: California: Jacumba, 15-VIII-15, Pinus monophylla. Colorado: Colorado N.M., 25-X-35, P. edulis.

Host.- Pinus monophylla, P. edulis.
Notes. - The above treatment was based on the holotype, on five paratypes, and on eight other specimens.

## 35. Pityophthorus pinguus (Blackman)

 Fig. 209Myeloborus pinguus Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Pub. 25:17, 149, 153, 166, 178 (pinquus, p. 20, a lapsus calami) (Holotype, female; Longmont, Colorado; U.S. Nat. Mus.. 41261)

Diagnosis.- This species is distinguished from other members of the ramiperda group by the absence of a frontal carina (obscure in an occasional specimen), by having antennal suture 2 located at or beyond the middle of
the club, and by the normal, nonconvex elytral interstriae 8.

Female.- Length 1.9-2.3 mm, 2.6 times as long as wide; color very dark brown, almost black.

Frons broadly convex, surface brightly shining, very coarsely, closely, deeply punctured, interspaces narrower than diameter of a puncture; vestiture of fine, short, inconspicuous hair. Antennal club 1.05 times as long as wide, suture 2 slightly beyond middle.

Pronotum 1.03 times as long as wide; outline about as in boycei Swaine except anterior margin more narrowly rounded, armed by six to eight serrations, discal punctures coarser, deeper, their margins not granulate.

Elytra 1.6 times as long as wide, 1.7 times as long as pronotum; outline as in boycei; striae 1 slightly impressed toward declivity, others not impressed, punctures rather fine, spaced by one to two diameters of a puncture; interstriae smooth, slightly more than twice as wide as striae, almost impunctate. Declivity convex, steep; strial punctures very minute, almost obsolete; interstriae 1 distinctly elevated, with a few minute granules, 2 twice as wide as 1 , smooth, impunctate, 3 armed by a sparse row of fine granules. Vestiture of fine, short, strial hair on disc, slightly longer on declivital interstriae 1 and 3.

Male. - Similar to female except frons more strongly convex, teeth on anterior margin of pronotum slightly larger.

Distribution.- E Nevada and Wyoming to Arizona and New Mexico.

USA: Arizona: Carr Canyon in Huachuca Mts., Chiricahua Mts., Santa Catalina Mts. Colorado: Longmont. Nevada: Baker. New Mexico: Capitan Mts., Emery Pass. Utah: Bryce Canyon N.M., Logan Canyon, Logan Dry Canyon, Panguitch. Widtsoe. Wyoming: Casper, Russell Creek in Shoshone N.F.
Hosts.- Pinus flexilis, P. strobiformis.
Biology.- Specimens were taken from the cambium of small branches.

Notes.- The above treatment was based on 36 specimens.

## 36. Pityophthorus separatus Bright

Pityophthorus separatus Bright, 1977, Canadian Ent. 109:529 (Holotype, male; Poinsett State Park, South Carolina; Wood Coll.)
Diagnosis.- This species is distinguished from boycei Swaine by the more finely
punctured pronotal dise and by the very different declivity as described below.

Female.- Length $2.4 \mathrm{~mm}, 2.8$ times as long as wide; color dark brown.

Frons as in boycei except punctures slightly smaller.

Pronotum as in boycei except punctures on posterior half much smaller, their rims not armed by a granule.

Elytra as in boycei except discal punctures not as deep, slightly smaller; declivity convex, sulcus feeble or absent, striae 1 and 2 punctured to apex, interstriae 2 indistinctly wider than 1 , not impressed, with a row of fine, feebly granulate punctures. Vestiture largely confined to posterior half except on sides, consisting of moderately long, rather fine interstrial setae on all interstriae including 2.

Distribution.- South Carolina.
USA: South Carolina: Poinsett State Park, 2()-VII-57, blacklight, V. M. Kirk.

Notes.- The above treatment was based on the holotype.

## 37. Pityophthorus boycei Swaine

 Fig. 209Pityophthorus boycei Swaine, 1925, Canadian Ent. 57:192 (Holotype, male; Cisco, Placer Co., California; Canadian Nat. Coll., 1368.)
Myeloborus catulus Blackman. 1928, New York St. Coll. For., Syracuse, Tech. Pub. 25:21 (Holotype, female; Clark's Fork, Idaho; U.S. Nat. Mus., 41262); Bright, 1976, Great Basin Nat. 36:426. Synomymy
Myelohorus iniquus Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Pub. 25:27 (Holotype, female; Kevstone, Wyoming; U.S. Nat. Mus., 41264): Bright, 1976, Great Basin Nat. 36:426. Synonymy
Pityophthorus siouxensis Bright, 1977, Great Basin Nat. 36:439 (Holotype, female; Black Hills, South Dakota; Canadian Nat. Coll.); Wood, 1977. Great Basin Nat. 37:387. Synonymy
Diagnosis.- This species is distinguished from ramiperda Swaine by the presence of small granules on the lateral or posterolateral margins of discal punctures on the pronotum, by the flat (not elevated) declivital interstriae 3 where it joins 9 , and by the less strongly convex frons.

Female.- Length 1.9-2.9 mm, 2.6 times as long as wide; color very dark brown.

Frons longitudinally almost flat from epistoma to upper level of eyes, transversely
rather broadly convex; surface shining, somewhat irregular, punctures moderately coarse, close; some specimens with a low, weak median carina of variable length; vestiture fine, short, inconspicuous. Antennal club 1.15 times as long as wide, sutures 1 and 2 on basal half, slightly procurved, aseptate.

Pronotum 1.1 times as long as wide; widest near base, rather weakly arcuate on basal two-thirds, rather broadly rounded in front; anterior margin armed by about 12 teeth; posterior areas shining, indistinctly, feebly wrinkled, punctures moderately fine, several punctures behind summit each armed on lateral or posterior margin by a fine granule; median line impunctate. Vestiture of fine, short hair.

Elytra 1.7 times as long as wide, 1.6 times as long as pronotum: sides almost straight and parallel on basal two-thirds, then slightly converging, broadly rounded behind; striae 1 feebly, others not impressed, punctures fine, shallow, spaced within row by three to four diameters of a puncture; interstriae shining, not entirely smooth, about five times as wide as striae, punctures very fine, widely spaced. Declivity steep, convex; strial punctures very fine, but distinct in most specimens; interstriae 1 rather narrowly, distinctly elevated, 2 shallowly, rather broadly impressed, at middle as wide as 1 , narrower below, 3 indistinctly elevated, armed by a row of about six very fine granules, 8 weakly convex from base of declivity to just anterior to junction with 3. Vestiture restricted to sides; declivity glabrous, a few short setae often present on dise.

Male. - Similar to female except frons more distinctly convex, transverse impression above epistoma weakly developed; median serrations on anterior margin of pronotum usually slightly larger.

Distribution.- British Columbia and California to South Dakota and Colorado.

CANADA: British Columbia: Weywick Lake at Cariboo, 13-V1-62, G. G. E. Scudder. USA: California: Bridal Veil Meadows in Mariposa Co., Cisco, Donner Pass, Ebbetts Pass, Kingvale, Meyers, Mono Hot Springs in Fresno Co., Tuolumne Meadows. Colorado: Fairplay, Jefferson, Pike N.F., Pine. Pingree Park, Poudre Canyon. Idaho: Clark Fork. Montana: Melville. Oregon: Williamson River in Klamath Co. South Dakota: Black Hills. Wyoming: 25 km SW Buffalo, Black Hills, Cody Canyon, Keystone, Sheridan, Yellowstone Lake.

Hosts.- Pinus aristata, P. contorta, $P$. ponderosa.

Biology.- This is apparently a primary enemy of pine. The adult beetles construct pith tunnels in healthy, green, leaf-bearing twigs, where they deposit their eggs. The larvae enlarge and extend the parental tunnel and emerge before the needles on infested twigs turn brown. Infested twigs usually are detected when the wind breaks them, thus causing them to fall to the ground. Severe infestations have been observed.

Notes. - The above treatment was based on the holotypes of boycci, iniquus, catuhus, and siouxensis, and on 133 other specimens.

## 38. Pityophthorus amplus (Blackman)

Fig. 209

Myeloborus amplus Blackman. 1928, New York St. Coll. For., Syracuse, Tech. Pub. 25:18 (Holotype, female; Kaibab N.F., Arizona: U.S. Nat. Mus., 41259)

Diagnosis.- This species is distinguished from ramiperda Swaine by the near absence of a frontal carina, by the coarser elytral punctures, and by the different elytral declivity as described below.

Female.- Length 2.1-3.0 mm, 2.6 times as long as wide; color very dark brown, elytra usually lighter.

Frons less strongly convex than in ramiperda, with median carina usually obsolete, punctures finer, sparse.

Pronotum as in ramiperda except punctures rather coarse.

Elytra about as in ramiperda except punctures conspicuously larger, declivital interstriae 2 at least twice as wide as 1 (one and one-half times or less in ramiperda), 8 feebly convex on declivity.

Male.-Similar to female except a weak, longer median frontal carina evidently always present.

Distribution.- Arizona to New Mexico.
USA: Arizona: Flagstaff, 12-V-2I, 24-VI-25, 25-VII-26, Pinus ponderosa, M. W. Blackman; Kaibab N.F., 25-VII26, K-219, Pinus ponderosa, M. W. Blackman, same data except 12-VI-25, K-63; Chiricahua Mts. bred 26-IX, P. ponderosa, Hopk. 5793, J. L. Webb; Prescott N.F., 4-VI10, Hopk. 20404j; Santa Catalina Mts. New Mexico: Lincoln N.F., Hopk. U.S. 37218-L, Pinus "flexilis"; Sacramento Mits.

Host.-Pinus ponderosa, P. strobiformis.

Notes. - The above treatment was based on the holotype, on 12 paratypes, and on 2 other specimens.

## 39. Pityophthorus ramiperda Swaine

Figs. 208, 209
Pityophthorus ramiperda Swaine, 1917, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(1):28 (Holotype, female; Ile Perrot, Quebec; Canadian Nat. Coll., 3150)
Myeloborus fizasi Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Pub. 25:23 (Holotype, female: Cranberry Lake, New York: U.S. Nat. Mus., 41263); Bright, 1976, Great Basin Nat. 36:426. Synonymy
Diagnosis.- This species is distinguished from boycei Swaine as indicated in the diagnosis of that species and in the following treatment.

Female.- Length 1.9-2.6 mm, 2.7 times as long as wide; color very dark brown.

Frons as in boycei except very slightly more strongly convex.

Pronotum as in boycci except discal punctures never armed by granules.

Elytra as in boycei except discal punctures slightly larger; lower part of declivital interstriae 3 convex, joining convex apex of 8 (not always distinct.)

Male.- Similar to female except differing as in boycei.

Distribution.- Wisconsin and Quebec to New York.

CANADA: Ontario: Bob's Lake. Quebec: Ile Perrot. USA: Maine: Bar Harbor, "Maine Coast." Massachusetts: Belchertown, Beverly, Rozbury, Wellesley. Michigan: Manitowoc Co., Romeo. New York: Cranberry Lake, Niagara. Rhode Island: Burville, Gloucester, Washington Co. Vermont: Danbury. Wisconsin: Amery in Polk Co.

Hosts.- Pinus resinosa, P. strobus.
Biology.- Evidently similar to boycei (Blackman 28:24).

Notes. - The above treatment was based on the holotypes of ramiperda and fivasi and on 56 other specimens.

## 40. Pityophthorus deleoni (Blackman)

Myeloborus deleoni Blackman, 1942, Proc. U.S. Nat. Mus. 92:201 (Holotype, female; El Seco, Puebla, Mexico U.S. Nat. Mus., 55975)
Diagnosis.- This species is distinguished from ramiperda Swaine by the larger size, by the reticulate, more finely punctured elytral
disc, and by other characters described below.

Female.- Length $3.0-3.5 \mathrm{~mm}, 2.6$ times as long as wide; color very dark brown, elytra reddish brown.

Frons broadly, transversely convex, weakly, transversely impressed above epistoma, then longitudinally almost flat to upper level of eyes, a weak, median carina at epistoma, sometimes ending on lower fourth, occasionally extending to upper level of eyes; surface smooth, shining, punctures fine, moderately close; vestiture fine, short, inconspicuous, longest about equal in diameter to four facets.

Pronotum outline about as in ramiperda; surface of posterior areas weakly reticulate, punctures fine, deep, close, a few with a minute granule on lateral margin. Vestiture fine, short, moderately abundant.

Elytra outline about as in ramiperda; striae not impressed, punctures in slightly confused rows, punctures rather coarse, deep; interstriae about twice as wide as striae, very obscurely subreticulate, 1 and 3 punctured, 2 and 4 with a few punctures at base and near declivity. Declivity steep, shallowly bisulcate; striae 1 moderately impressed, punctures on 1 and 2 almost as large as on disc, impressed; interstriae 1 moderately elevated, shining, a row of very minute granules present, 2 moderately impressed, flat to ascending very slightly laterally, almost smooth, impunctate, 3 convex, slightly higher than 1 , with moderately abundant, fine, confused punctures near base, becoming minutely granulate below, convexity of 3 joins distinctly convex 8 . Disc and declivity usually glabrous; some short setae on sides.

Male. - Similar to female except frons shallowly, transversely impressed to upper level of eyes, median carina much stronger, subacute to upper level of eyes.

Distribution.- Nuevo León to Puebla.
MEXICO: Puebla: El Seco, 7-III-36, Pinus, 685, D. DeLeon. Nuevo León: Chapinque Mesa near Monterey, 23-VI-71, Pinus, D. E. Bright.
Notes.- The above treatment was based on the holotype, on five paratypes, and on three other specimens.

## 41. Pityophthorus comosus Blackman

Pityophthorus comosus Blackman. 1928, New York St. Coll. For., Syracuse, Tech. Pub. 25:65 (Holotype, female; Sacramento Mountains, New Mexico: U.S. Nat. Mus., 41284)

Pityophthorus foratus Wood, 1967, Great Basin Nat. 27:40 (Holotype, female; 10 miles W El Salto, Durango, Mexico; Canadian Nat. Coll.); Bright, 1977, Canadian Ent. 109:514. Synonymy
Diagnosis.- This species is distinguished by the large size, by the confused elytral punctures, by the very long, fine, elytral hair, and by the distinctive male frons that lacks a median carina.

Female.- Length $2.3-3.2 \mathrm{~mm}$, 2.4 times as long as wide; color very dark brown, elytra usually reddish brown.

Frons broadly convex, with central third subconcavely impressed, punctures coarse in lateral areas (New Mexico); more broadly impressed to upper level of eyes, more finely punctured over greater area, particularly laterally (Durango); vestiture rather sparse, long, longest setae equal to about one-third distance between eyes.

Pronotum 1.0 times as long as wide; widest at base, sides weakly arcuate, converging toward rather narrowly rounded anterior margin; anterior margin armed by about 8-12 irregular, low serrations; posterior areas smooth, shining with numerous indistinctly impressed points, punctures rather coarse, deep, close. Vestiture of fine, long hair.

Elytra 1.5 times as long as wide, 1.7 times as long as pronotum; striae 1 weakly impressed toward declivity; discal surface smooth, shining, punctures strongly confused, coarse, deep, close, mostly separated by distances less than diameter of a puncture. Declivity steep, very broadly, shallowly bisulcate; striae 1 and 2 rather coarsely punctured, punctures in lateral areas confused; interstriae 1 rather narrowly convex, 2 three times as wide as 1 , smooth, shining, impunctate, with numerous impressed points, lateral areas convex, as high as 1 , unarmed. Vestiture fine, very long hair (in Durango specimens half as long as in New Mexico specimens).

Male.- Similar to female except frons with a broad, strong, transverse impression occupying upper half of area below upper level of eyes, area below impression occupied by a strong transverse elevation, surface
shining, coarsely punctured, vestiture short, sparse, inconspicuous.

Distribution.-Arizona and New Mexico to Durango.

USA: Arizona: Chiricahua Mts., Parmerly in Cochise Co. New Mexico: Cloudcroft, Sacramento Mts. MEXICO: Durango: El Salto.

Host.-Pinus ponderosa.
Brology.- Specimens were taken from branches 3 cm in diameter.

Notes.- The above treatment was based on the holotypes of comosus and foratus and on 55 other specimens. As indicated above, the length of the elytral hair and the sculpture of the female frons differs rather strikingly between the series from New Mexico and Durango. The Durango specimens are also smaller. Although different subspecies could be represented, more material is needed from northern Mexico to resolve the problem.

## 42. Pityophthorus arceuthobii Wood

Pityophthorus arceuthobii Wood, 1971, Brigham Young University Sci. Bull., Biol. Ser. I5(3):48 (Holotype, female: 96 km W Durango, Durango, Mexico; Wood Coll.)
Diagnosis.- The relationship of this species to others in the comosus group is remote. It is distinguished by the smaller size, by the more slender form, by the less densely placed elytral punctures, and by the declivital and frontal characters described below.

Female.- Length $1.8-2.0 \mathrm{~mm}, 2.7$ times as long as wide; color very dark brown, elytra usually lighter.

Frons plano-convex, with a slight transverse impression on lower third, epistomal margin weakly elevated; surface subshining, rather coarsely, closely punctured on a semicircular area; vestiture of fine, rather long hair of equal length almost uniformly distributed over punctured area. Antennal club with suture 1 straight, segments 2 and 3 about equal in width.

Pronotum 1.0 times as long as wide; widest near base, sides almost parallel on slightly less than basal half, weakly constricted on anterior half, rather broadly rounded in front; anterior margin armed by about 10 small, irregularly formed teeth; posterior area reticulate, punctures coarse, deep. Glabrous except at margins.

Elytra 1.6 times as long as wide; 1.7 times as long as pronotum; sides almost straight and parallel on basal two-thirds, then slightly converging, broadly rounded behind; striae 1 narrowly impressed on posterior half of disc; striae moderately confused, punctures large, deep, only moderately close, equal in size and appearance with slightly less abundant, confused, interstrial punctures; surface shining, not completely smooth. Declivity rather steep, broadly, shallowly sulcate; punctures on striae 1 and 2 minute but distinct; interstriae 2 wide, smooth, moderately impressed, 1 sharply, slightly elevated, bearing about six minute granules, 3 gradually, broadly raised, punctures very feebly granulate. Vestiture of sparse, rather short, coarse hair, mostly on sides.

Male. - Similar to female except frons more strongly convex above, lower half with a rather thick, low, median carina that gradually increases in height to summit just above epistoma, surface subreticulate, less regularly punctured, frontal vestiture sparse, short; granules on elytral declivity scarcely evident.

Distribution.- Durango to Mexico.
MEXICO: Durango: 96 km W Durango, 5-VI-65, 2500 m , No. 27, S. L. Wood. Mexico: 5 km W Río Frío.

Host.-Arceuthobium globosum (parasite on Pinus montezuma).

Biology. - Specimens were removed from shoots $1-3 \mathrm{~cm}$ in diameter in tunnels parallel to but below the cambium.

Notes.- The above treatment was based on the type series of 40 specimens and on 7 other specimens.

## 43. Pityophthorus aztecus Bright

Pityophthorus aztecus Bright, 1977, Canadian Ent. 109:520 (Holotype, female; km 50 Mexico-Puebla, Mexico; U.S. Nat. Mus.)
Diagnosis.- This species is distinguished from dispar Bright by the much finer, more widely spaced punctures on the elytral disc.

Female.- Length $2.3-3.6 \mathrm{~mm}, 2.5$ times as long as wide; color dark brown except elytra reddish brown.

Frons as in schwerdtfergeri (Schedl) except punctures distinctly smaller.

Pronotum as in schwerdtfergeri except disc rather strongly reticulate, punctures slightly smaller.

Elytra as in schwerdtfergeri except punctures conspicuously smaller, declivital interstriae 2 wider, about one and one-half times as wide as 1 .

Male.- Similar to female except frons more strongly convex, more coarsely punctured, a low median carina on lower half, most specimens with lower half weakly to moderately, transversely impressed (variable).

Distribution.- Mexico to Veracruz.
MESICO: Mexico: km 50 Mexico-Puebla, 23-I-60, Pinus, No. 16, 60-11564, Guerera; Río Frío, 1-IX-69, L. A. Kelton; 32 km N Cuernavaca, 15-VII-69, Pinus, D. E. Bright. Veracruz: Las Vigas, 5-VII-67, No. 157, small Pinus branches, S. L. Wood.

Notes.- The above treatment was based on the holotype and on 11 paratypes.

## 44. Pityophthorus dispar Bright

Pityophthorus dispar Bright. 1976, Great Basin Nat. 36:431 (Holotype. female; 7 miles or 11 km E San Cristóbal, Chiapas, Mexico: Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from aztecus Bright by the much coarser, closer, elytral punctures and by the uniformly dark color.
Female.- Length 2.1-2.8 mm, 2.5 times as long as wide; color almost black.

As in aztecus except pronotal and elytral punctures much coarser, closer.

Male.-Similar to female except frons as in aztecus except median carina reduced to a blunt, indistinct tubercle on epistoma.
Distribution.- Chiapas.
MEXICO: Chiapas: 7 miles or 11 km E San Cristóbal, I3-26-V-69, Pinus, also 8 mi or 13 km E. $P$. montezuma, P. ochoterenai, D. E. Bright.

Notes.- The above treatment was based on the type series of 21 specimens.

## 45. Pityophthorus schwerdtfergeri (Schedl)

Conophthorus sehwerdtfergeri Schedl, 1955, Zeitschr. angew. Ent. 38:28 (Lectotype, male; Rancho Alegre, Strasse Quezaltenango-Huehuetenango, Guatemala; Schedl Coll. designated by Bright, 1976, Coleopt. Bull. 30:187)
Pityophthorus islasi Wood, 1962, Great Basin Nat. 22:80 (Holotype, female: Temascaltepec, Mexico, Mexico: Wood Coll.); Wood. 1966. Great Basin Nat. 26:28. Synonymy
Conophthocranulus islasi Schedl, 1963, Ent. Arb. Mus. Frey I4:I63 (Holotype, female; Temascaltepec. Mexico; Schedl Coll.); Wood, 1966, Great Basin Nat. 26:28. Synonymy

Diagnosis.- This species is distinguished from comosus Blackman by the very different frons in both sexes, by the more convex, very feebly sulcate elytral declivity, and by the shorter elytral hair.

Female.- Length $2.2-2.8 \mathrm{~mm}, 2.4$ times as long as wide; color dark reddish brown.

Frons broadly plano-convex from epistoma to above upper level of eyes; surface smooth, shining, punctures rather fine, less numerous in central area; vestiture of fine, moderately abundant, moderately long hair, a few hairs at margin slightly longer. Antennal club with sutures 1 and 2 moderately arcute.

Pronotum 1.0 times as long as wide; outline as in comosus; summit poorly defined, asperities in lateral areas extending to basal fourth; posterior areas obscurely subreticulate, punctures rather fine, most not circular, some in lateral part of disc armed by a granule. Vestiture rather sparse, moderately short.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; outline and disc about as in comosus. Declivity convex, steep; striae 1 and 2 with punctures in rows, almost as large as on disc; interstriae 1 slightly elevated, with a row of punctures, 2 flat, not impressed, impunctate, with numerous points, slightly wider than 1,3 broadly rounded, unarmed. Vestiture of erect, moderately long hair, stouter on declivity except absent on interstriae 2.

Male.- Similar to female except frons deeply excavated almost from eye to eye from upper level of eyes two-thirds of distance toward epistoma, excavation divided by a median carina, carina extending at summit on epistomal margin, surface rather coarsely punctured, vestiture inconspicuous.

Distribution.- Nevada and Arizona to Honduras.

USA: Arizona: Chiricahua Mts., 12-VIII-52, J. N. Knull; Globe R. D. Nevada: Kyle Creek, Clark Co., 24-IX-69. Pimus ponderosa, D. F. Zoller. Texas: Jeff Davis Co., 20-VI-52. J. N. Knull. MEAICO: Chiapas: Lazardo Cardenas, 26-VI-69. Pitus ooearpa, D. E. Bright. Durango: El Salto. 25-III-74. Pinus. M. M. Furniss. Mexico: Temascaltepec, 17-VIII-60, P. oocarpa, F. Islas. Nuevo León: Chapinque Mesa, 26-IV-69, D. E. Bright. GUATEMALA: Rancho Alegre on the HuehuetenangoQuezaltenango road. HONDURAS: Tegucigalpa, IS-I68, P. pseudostrobus, E. W. Clark.

Hosts.- Pinus oocarpa, P. ponderosa, P. pseudostrobus.

Biology.- Specimens were taken from deformed cones and from twigs.

Notes.- The above treatment was based on the syntypes of schwerdtfergi, on the holotypes of islasi Wood and islasi Schedl, and on 32 other specimens.

## 46. Pityophthorus pulicarius (Zimmermann)

Crypturgus pulicarius Zimmermann, 1868, Trans. Amer. Ent. Soc. 2:144 (Lectotype, sex?; Lake Superior, as indicated by small blue card on pin of type; Mus. Comp. Zool., designated by Bright, 1976. Coleopt. Bull. 30:187)
Cryphalus pulicarius: LeConte, 1868, Trans. Amer. Ent. Soc. 2:155
Pityophthorus pulicarius: LeConte, 1876, Proc. Amer. Philos. Soc. 15:353
Pityophthorus cubensis Schedl, 1972, Koleopt. Rundsch. 50:65 (Holotype, male; Vinales, Pinar del Río Prov., Cuba; Schedl Coll.); Wood, 1977, Great Basin Nat. 37:210. Synonymy
Diagnosis.- This species is distinguished by the coarse, deep, confused punctures on the elytral disc, by the evenly convex male frons that lacks a carina, and by the coarsely punctured declivital striae 1 and 2 , with interstriae 2 equal in width to 1 .

Female.- Length $1.5-2.2 \mathrm{~mm}, 2.4$ times as long as wide; color dark reddish brown.

Frons broadly, transversely convex, very shallowly, transversely impressed between epistoma and upper level of eyes; surface shining, punctures rather coarse, deep, close except finer on median area of lower half, vestiture of rather sparse, fine, moderately long hair to slightly above upper level of eyes.

Pronotum 1.1-1.2 times as long as wide; widest at base, sides feebly arcuate and converging very slightly on basal half, rather broadly rounded in front; anterior margin armed by about $10-12$ low serrations; summit not well defined, slightly in front of middle; posterior areas smooth, shining, with numerous impressed points (occasional specimens subreticulate), punctures coarse, very close, deep. Hairlike vestiture confined to margins, short.

Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; sides subparallel, very feebly arcuate on basal two-thirds, very broadly rounded behind; striae not impressed; surface smooth, brightly shining, punctures coarse, deep, strongly confused,
mostly spaced by distances less than diameter of a puncture. Declivity very steep, broadly convex; punctures of striae 1 and 2 in rows, rather coarse, deep, those in lateral areas often in indistinct rows; interstriae 1 distinctly elevated, with a row of fine punctures, 2 smooth, shining, impunctate, as wide as 1 , moderately impressed, 3 and lateral areas broadly rounded, as high as 1, punctured, without granules. Vestiture usually confined to sides and declivity, rather sparse, short.

Male. - Similar to female except frons rather strongly, uniformly convex, more coarsely punctured; glabrous.

Distribution.- Minnesota and Nova Scotia to Texas, Florida, and Cuba.

CANADA: Ontario, Quebec, Nova Scotia. USA: Alabama, Arkansas, Commecticut, Florida, Georgia, Illinois, Louisiana, Maine, Maryland, Massachusetts, Michigan, Minnesota, Mississippi, New Jersey, New York, North Carolina, Ohio, Pennsylvania, Rhode Island, South Carolina, Texas, Virginia, West Virginia, Wisconsin. CUBA: Pinar del Río.

Hosts.- Pinus caribaea, P. echinata, P. palustris, P. resinosa, P. rigida, P. strobus, P. sylvestris, $P$. taeda, P. virginiana.

Biology.- This species breeds in the pith of small twigs.

Notes.- The original description does not specify a locality or type. Of 10 presumed syntypes in the LeConte collection, the first, a male, is color coded for Lake Superior, the second is for the southern states, specimens 3-6 are labeled Tampa, Florida, 8-9 are labeled Maryland, and 10 is from Illinois. These syntypes and 534 other specimens were used as a basis for the above treatment.

## 47. Pityophthorus solus Blackman

Pityophthorus solus Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Pub. 25:64 (Holotype, male? Pinal Mountains, Arizona; U.S. Nat. Mus., 4128.3)

Pityophthorus cribratus Blackman, 1942, Proc. U.S. Nat. Mus., 92:216 (Holotype, female; Mexico, Distrito Federal, Mexico; U.S. Nat. Mus., 55990); Bright, 1977, Canadian Ent. 109:518. Synonymy
Diagnosis.- This species superficially resembles pulicarius (Zimmermann), but is distinguished by the more slender form, by the distinct pronotal summit, by the very different elytral declivity, and by other characters.

Female.- Length $1.5-2.6 \mathrm{~mm}, 2.7$ times as long as wide; color reddish brown.

Frons broadly convex, a slight transverse impression between summit and upper level of eyes, epistoma slightly elevated at median line; surface shining and rather coarsely, closely punctured to upper level of eyes; vestiture of sparse, rather long hair below upper level of eyes.

Pronotum 1.1 times as long as wide; outline about as in pulicarius except anterior margin more broadly rounded and more coarsely serrate; summit slightly in front of middle, with a distinct posterior impression, posterior areas with surface smooth, shining, impressed points very obscure, moderately coarse, deep, spaced approximately by diameter of a puncture. Vestiture absent on disc, of short hair.
Elytra 1.7 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; disc with coarse, confused punctures as in pulicarius. Declivity steep, broadly convex; striae 1 and 2 coarsely, deeply punctured; interstriae 1 distinctly, gradually elevated, 2 much wider than 1 , shallowly sulcate, smooth, shining, coarsely, deeply punctured, punctures confused, 3 with a few very obscure, rounded minute granules. Vestiture of fine, erect, moderately long hair on disc and sides, distinctly longer and coarser on declivital interstriae 3 and lateral areas.

Male. - Similar to female except frons rather strongly, transversely impressed from epistoma to well above eyes, coarsely punctured, aciculate near epistoma.

Distribution.-Arizona and New Mexico to Chiapas.

USA: Arizona: Pinal Mts., Wickham, 147. New Mexico: Cloudcroft, Hopk. 342I8-E2, Penasco, 2-IV-70, I4-VII-70, in flight, J. R. McClellan. MEXICO: Chiapas: San Cristóbal, Yerba Buena. Distrito Federal: Mexico City. Durango: El Salto, El Palmito. Mexico: Iz-taccihuatl-Popocatepetl N.P. Oaxaca: Oaxaca, Suchixtepec, Valle Nacional.

## Hosts.- Pinus spp.

Notes.- The above treatment was based on the holotypes of solus and cribratus and on 141 other specimens.

## 48. Pityophthorus aciculatus Bright

Pityophthorus aciculatus Bright, 1976, Canadian Ent. 109:519 (Holotype, female; San Cristóbal, Huehuetenango, Guatemala; Wood Coll.)

Diagnosis.- This species is distinguished from solus Blackman by the larger size, by the smaller elytral punctures, by the deeper declivital sulcus, and by the very different frons.

Female.- Length 1.9-2.5 mm, 2.6 times as long as wide; color dark reddish brown.

Frons weakly convex; smooth, shining, coarsely, closely, deeply punctured, often obscurely aciculate, a distinct, short, median carina on lower third; vestiture moderately abundant, a few setae rather long, not forming a brush.

Pronotum as in solus except punctures on posterior half larger, closer.

Elytra as in solus except punctures on disc deeper, slightly smaller, declivity not as steep, sulcus more distinctly impressed, punctures on declivity distinctly smaller.

Male.- Frons rather strongly, transversely impressed, aciculation much more conspicuous.

Distribution.- Mexico to Guatemala.
MEXICO: Mexico: Ocoyoacac, I6-VII-69. Pitus teiophylla, D. E. Bright. GÚatemala: San Cristóbal, Huehuetenango, $28-\mathrm{V}-64,2300 \mathrm{~m}$, No. 637, Pinus pseudostrobus. S. L. Wood.

Notes.- The above treatment was based on the type series of 46 specimens.

## 49. Pityophthorus carmeli Swaine

Pityophthorus carmeli Swaine, 1918, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(2): 100 (Holotype, female; Carmel, California; Canadian Nat. Coll., I372)
Pityophthorus torreyanae Swaine, 1918, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. I4(2):I0I (Holotype, female; San Diego, California; Canadian Nat. Coll., I370); Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Bull. 25:98. Synonymy
Diagnosis.- This species superficially resembles solus Blackman, from which it is distinguished by the very different frons, by the elytral punctures on the disc being in more or less definite rows, and by the impunctate declivital interstriae 2.

Female.- Length $1.9-2.7 \mathrm{~mm}, 2.7$ times as long as wide; color dark brown.

Frons shallowly concave from eye to eye from epistoma to well above upper level of eyes; surface smooth, shining, uniformly rather coarsely, closely punctured; vestiture of rather abundant, fine hair, rather short in
central area, very long on lateral and dorsal margins.

Pronotum 1.1 times as long as wide; outline essentially as in solus except median teeth on anterior margin distinctly larger; posterior areas smooth to subreticulate, with numerous, minute, impressed points, punctures deep, moderately coarse, rather close. Vestiture of fine, short hair.

Elytra 1.8 times as long as wide, 1.7 times as long as pronotum; outline as in solus; striae 1 weakly, others not impressed, punctures moderately large, deep, mostly in rows; interstriae almost smooth, shining, with many transverse lines emanating from strial punctures, punctures distinctly smaller than those of striae; rather widely spaced. Declivity steep, broadly convex; punctures on striae 1 and 2 very fine, a few of them evidently replaced by granules; interstriae 1 distinctly elevated, with a row of very minute granules, 2 about twice as wide as 1 , moderately impressed on mesal side, weakly on lateral side, surface smooth, shining, with impressed points, 3 with a row of very fine granules. Vestiture of minute strial hair and moderately long interstrial hair, not longer on declivity.

Male. - Similar to female except frons broadly convex, rather coarsely, more closely punctured, a distinct median callus (often subcarinate) near upper level of eyes, vestiture sparse, inconspicuous.

Distribution.-California.
USA: California: Alameda, Lake, Marin, Monterey, San Diego, San Luis Obispo, Santa Clara, Santa Cruz, and Sonoma Counties.

Hosts.-Pinus attenuata, P. coulteri, P. muricata, P. radiata, P. torreyana.

Biology.- These beetles breed in small twigs and produce at least two overlapping generations each year.

Notes.- The above treatment was based on the holotypes of cameli and torreyanae and on 251 other specimens.

## 50. Pityophthorus scabridus Schedl

Pityophthorus scabridus Schedl, 1955, Zeitschr. angew. Ent. 38:24 (Lectotype, female; Quezaltenango, Guatemala; Schedl Coll., designated by Bright. 1976. Coleopt. Bull. 30:186)

Diagnosis.- This species is distinguished from the remotely allied carmeli Swaine by
the stouter body form, by the very different frons, by the subreticulate pronotum, by the coarsely punctured elytra, and by the very different elytral declivity.

Female.- Length $1.9-2.4 \mathrm{~mm}, 2.4$ times as long as wide; color dark reddish brown.

Frons broadly flattened to well above eyes, epistoma ascending toward margin; surface smooth, shining, finely, very closely punctured; vestiture rather abundant, uniformly distributed, moderately long, only slightly longer at margins.

Pronotum 1.1 times as long as wide; outline about as in cameli; posterior areas subreticulate, impressed points evident, punctures rather coarse, moderately close, deep. Glabrous except for short hair at margins.

Elytra 1.4 times as long as wide, 1.5 times as long as pronotum; sides straight and parallel on basal two-thirds, very broadly rounded behind; striae not impressed, surface subreticulate, shining, punctures from suture to interstriae 3 strongly confused, in recognizable rows in lateral areas, punctures coarse, deep, close. Declivity very steep, shallowly bisulcate; striae 1 and 2 distinct, punctures rather fine; interstriae 1 convex, distinctly elevated, armed by a row of fine tubercles, 2 strongly impressed, subreticulate, slightly wider than 1,3 distinctly elevated, higher than 1 , armed by a row of about nine rather fine tubercles. Vestiture of minute strial hair and moderately long, coarser interstrial hair, rather stout on declivital interstriae 3 .

Male.- Similar to female except frons broadly convex, rather coarsely, closely punctured, a subcarinate median callus on upper half, vestiture sparse, fine, rather short.

Distribution.- Nayarit to Honduras.
MEXICO: Chiapas: 6 km N Bochil, 10-V-69, Pinus, D. E. Bright; Lagos des Colores, 17-V-69, P. oocarpa, D. E. Bright; San Cristóbal, 26-V-69. Pinus, D. E. Bright. Jalisco: 24 km W Guadalajara, 19-V11-52, Pinus. S. L. Wood. Mexico: 32 km N Cuernavaca, 15-VII-69, Pinus, D. E. Bright. Nayarit: Laguna Santa María, 6-VII-65, 1000 m, No. 204, Pinus, S. L. Wood. Oaxaca: 41 km SE Nochixtlán, 17-V1-67, No. 56, Pinus, S. L. Wood. Veracruz: Las Vigas, 5-V1-62, Pinus, R. Coronado. GUATEMALA: Quezaltenango, 26-V-64, 1600 m , No. 622, $P$. pseudostrobus, S. L. Wood; Volcán de Agua, 19-V-64, 1000 m , No. 596, P. pseudostrobus, S. L. Wood; San Juan. HONDURAS: Tegucigalpa, 9-1II-66, P. oocarpa; Yuscarán, 23-IV-64, 800 m , No. 518, P. caribaea, S. L. Wood.

Hosts.-Pinus caribaea, P. oocarpa, P. pseudostrobus.

Biology.- Specimens were taken from small branches.

Notes.- The above treatment was based on the Schedl syntypes and on 215 other specimens.

## 51. Pityophthorus leechi Wood

Pityophthorus leechi Wood, 1977, Great Basin Nat. 37:215 (Holotype, female: 3 km NNE Angwin on N side of Howell Mt., Napa Co., California: California Acad. Sci.)
Diagnosis.- This species is distinguished from scalptor Blackman by conspicuous characters of the female frons as indicated below.
Female.- Length $2.0-2.5 \mathrm{~mm}, 2.8$ times as long as wide; color reddish brown.

Frons transversely impressed on area below upper level of eyes, very feebly concave on median half of impressed area; surface smooth, shining, punctures moderately coarse, almost uniformly distributed, interspaces about equal to diameter of a puncture; a weak epistomal process clearly indicated; vestiture much less abundant than in scalptor, almost uniformly distributed, rather short, only slightly longer in marginal areas, longest setae about equal to one-third distance between eyes.
Pronotum and elytra as in scalptor, perhaps less brightly shining and elytral vestiture very slightly longer.
Male-Similar to male scalptor except transverse frontal impression not as strong, median carina less strongly elevated.

Distribution.-California.
USA: California: 3 km NNE Angwin on N side of Howell Mt., Napa Co., 5-VI-77, Pinus ponderosa. H. B. Leech.

Biology.-Specimens were reared from small, shaded-out branches on a living host tree.

Notes.- The above treatment was based on the type series of 29 specimens.

## 52. Pityophthorus scalptor Blackman

Pityophthorus scalptor Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Pub. 25:30 (Holotype, female; Julian, California: U.S. Nat. Mus., 41265)
Diagnosis.- This speech is distinguished from borealis Swaine and its allies by the absence of small granules on the lateral margins of discal punctures on the pronotum, by the
reticulate elytra, and by the shallowly concave female frons.

Female.- Length 2.2-2.7 mm, 2.7 times as long as wide; color dark reddish brown.

Frons impressed from eye to eve, from epistoma to well above eyes, central half shallowly concave, ascending toward epistoma; epistomal process not indicated; surface smooth, rather dull, punctures rather fine, close, dense along lateral and dorsal margins; vestiture of fine, yellow hair, rather short in central area, very long on margins, longest setae equal in length to two-thirds distance between eyes.

Pronotum 1.1 times as long as wide; widest one-third pronotum length from base, sides moderately arcuate on basal two-thirds, distinctly constricted on anterior third, rather narrowly rounded in front; anterior margin armed by about 10 teeth, median pair rather coarse, rapidly decreasing in size laterally; summit slightly anterior to middle, with a slight posterior impression; disc smooth, shining, impressed points indicated; punctures rather fine, circular, with margins unarmed, moderately close. Glabrous except at margins.

Elytra 1.7 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, broadly rounded behind; striae not impressed except 1 near declivity, punctures rather small, in definite rows except slightly irregular on basal twothirds; surface reticulate, moderately shining, interstrial punctures fine, more widely spaced than those of striae, slightly confused on basal half, present on all interstriae. Declivity steep, convex, shallowly bisulcate; striae 1 impressed, punctures on 1 and 2 minute but visible; interstriae 1 distinctly elevated, armed by a row of fine granules, 2 almost one and one-half times as wide as 1 , impunctate, flat but ascending laterally, 3 rounded, higher than 1, armed by a row of minute granules similar to those on 1. Usually glabrous except at sides, occasional minute strial or interstrial hair on dise and declivity, without longer setae on declivity.

Male. - Similar to female except frons rather strongly convex on upper two-thirds, a shallow, transverse impression below, lower two-thirds with a fine, uniformly, sharply
elevated, low, median carina, surface coarsely punctured, subglabrous.

Distribution.- British Columbia to California.

CANADA: British Columbia: Elko. USA: California: Ebbetts Pass, Hat Creek, Mt. Julian, Laguna in Mariposa Co., McCloud, Mt. Wilson, Northfork, Palomar Mountain, Ventura Co., Yosemite Valley.

Hosts.- Pinus contorta, P. coulteri, P. jeffreyi, P. ponderosa.

Biology.- Specimens were taken from small branches of young trees. Apparently it is rather uncommon.

Notes. - The above treatment was based on the holotype and on 60 other specimens.

## 53. Pityophthorus scalptus Bright

Pityophthorus scalptus Bright, 1978, Great Basin Nat. 38:82 (Holotype, female; Aspen Grove, British Columbia; Canadian Nat. Coll., 15486)
Diagnosis.- This species is distinguished from scalptor Blackman by the more shallowly concave, more sparsely punctured female frons, by the tuberculate punctures on the pronotal disc, by the absence of elytral reticulation, by the absence of punctures on the even-numbered discal interstriae, and by the different declivity as described below.

Female.- Length 2.3-2.8 mm, 2.7 times as long as wide; color very dark brown.

Frons similar to scalptor except more evenly, more shallowly concave, punctures smaller, more widely spaced, separated by two to four diameters of a puncture, marginal row of long setae less dense.

Pronotum as in scalptor except all punctures armed or replaced by a small granule.

Elytra as in scalptor except surface smooth, shining, discal interstriae 2 and 4 impunctate, declivital interstriae 2 at least twice as wide as 1 , slightly more strongly impressed, tubercles on interstriae distinctly larger.

Distribution.- British Columbia to Colorado.

CANADA: British Columbia: Aspen Grove, 9-V1-31, 17357 Lot 31, Pinus ponderosa, H. Richmond. USA: Colorado: Estes Park, 31-V111-38, P. ponderosa, Hopk. US 31541-V. Montana: Stevensville, 31-VIII-67, P. ponderosa, Hopk. 51945. R. McEwan, M. McGregor.

Host.- Pinus ponderosa.
Notes. - The above treatment was based on 46 specimens.

## 54. Pityophthorus nitidus Swaine

 Fig. 209Pityophthorus nitidus Swaine, 1917, Dom. Canada Dept. Agric. Ent. Br. Tech. Bull. 14(1):25 (Lectotype, female; Tullochgoram, Quebec; Canadian Nat. Coll., 3151, designated by Bright, 1967, Canadian Ent. 99:678)
Pityophthorus borealis Swaine, 1925, Canadian Ent. 57:195 (Holotype, female; Coppermine River, Northwest Territories; Canadian Nat. Coll., 1368); Bright, 1977, Canadian Ent. 109:516. Synonymy
Pityophthorus anceps Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Pub. 25:31 (Holotype, female: Clyde, Colorado; U.S. Nat. Mus., 41266); Bright, 1977, Canadian Ent. 109:516. Synonymy Pityophthorus varians Schedl, 1930, Canadian Ent 62:196 (Holotype, female; Truro, Nova Scotia; Canadian Nat. Coll., 3133); Wood, 1957, Canadian Ent. 89:401. Synonymy
Pityophthorus aquilonius Bright, 1968, Canadian Ent. 100:604 (Holotype, female; Rampart House, Yukon Territory; Canadian Nat. Coll., 9733); Bright, 1977, Canadian Ent. 109:516. Synonymy
Diagnosis.- This species is distinguished from toralis Wood by the smaller average size, by the more strongly convex frons in both sexes, but with the transverse impression above the epistoma in the male much weaker, by the more finely punctured male frons, by the less abundant, shorter (variable) vestiture on the female frons, and by the near absence of punctures on the posterior twothirds of discal interstriae 2 and 4.

Female.- Length $1.6-2.4 \mathrm{~mm}, 2.9$ times as long as wide; color very dark reddish brown.

Frons variable, plano-convex over broad area to moderately convex, margins rounded, not specially marked by marginal punctures, puncture fine to moderately coarse, usually finer on lower half, rather close, deep; glabrous to moderately covered by fine, short setae of uniform length to more abundant, with marginal setae much longer (longest setae equal in length to one-third distance between eyes).

Pronotum 1.1 times as long as wide; outline as in scalptor Blackman; 10 serrations on anterior margin rather small, only slightly longer toward median line; posterior areas smooth, shining, with numerous impressed points, discal punctures lateral to median line oval, most with a granule on lateral margin.

Elytra 1.8 times as long as wide, 1.7 times as long as pronotum; outline as in scalptor; striae not impressed except 1 near declivity;
interstriae shining, varying from smooth to moderately wrinkled, three times as wide as striae, odd-numbered interstriae sparsely punctured throughout, even-numbered interstriae usually impunctate except on basal third. Declivity essentially as in scalptor except surface almost smooth, interstriae 2 at least twice as wide as 1 , more broadly impressed, ascending on lateral half only. Vestiture as in scalptor.

Male. - Similar to female except frons more strongly convex, more coarsely punctured, transverse impression weak, limited to lower fourth, vestiture short, sparse, inconspicuous.

Distribution.- Alaska and Newfoundland to Oregon and Nova Scotia.

ALASKA: Fort Yukon, Hope, Lawing, Seward Highway at mile 60. CANADA: Alberta: Highwood Pass. Smith. New Brunswick: Parkers Ridge, Kedwick Portage. Newfoundland: Birch Lake near White Bay, Deer Lake, Middlebrook. Northwest Territories: Aklavik. Coppermine River, Tumunuk. Ontario: Beardmore. Quebec: Ste. Anne's, Tullochgoram. Yukon: Rampart House, Johnson's Crossing. USA: Colorado: Clyde, Dolores. Oregon: Dixie Pass, Willamette Pass.

Hosts.-Picea engelmannii, P. glauca, P. mariana, Pinus resinosa, P. strobus, rare in other Pinus.

Notes.- The above treatment was based on the lectotype of nitidus, on the holotype and a topotypic female of borealis taken with the type series, on the holotypes of anceps, varians, and aquilonius, and on 428 other specimens.

This species is somewhat variable, particularly the female frons, but the material presently at hand is inadequate to properly evaluate that variation. This species is easily confused with alpinensis G. Hopping and toralis. The near absence of punctures on discal interstriae 2 and 4 and the host serve to distinguish this species.

## 55. Pityophthorus indigus Wood

Pityophthorus indigens Wood, 1977 (nee Wood, 1976), Great Basin Nat. 37:2I4 (Holotype, female: Gould, Colorado; Wood Coll.)
Pityophthorus indigus Wood, 1978, Great Basin Nat. 38:398. Replacement name
Diagnosis.- This species is distinguished from nitidus Swaine by the replacement of punctures on the pronotal disc by rounded
granules, by the minute strial punctures, and by the regularly punctured discal interstriae.

Female. - Length $2.0-2.3 \mathrm{~mm}, 2.8$ times as long as wide; color very dark brown.

Frons shining, rather strongly convex, rather coarsely, very closely punctured, upper margins of many punctures obscurely granulate; lower fourth marked by a blunt median carina, with its summit at its ventral end; vestiture sparse, very short, inconspicuous.

Pronotum as in nitidus except all discal punctures entirely replaced by rounded granules.

Elytra essentially as in nitidus except surface smooth, brightly shining, strial punctures minute, spaced within a row by three to five diameters of a puncture; interstriae about eight times as wide as striae, punctures more or less regular on all interstriae, minute, similar to those of striae. Declivity about as in nitidus except sulcus conspicuously deeper, granules on interstriae 1 and 3 distinctly larger.

Distribution.- Colorado.
USA: Colorado: 3 km E Gould, Jackson Co., I2-VI-69, Pinus contorta branch, S. L. Wood.

Notes.- The above treatment was based on the type series of six specimens.

## 56. Pityophthorus fuscus Blackman

Pityophthorus fuscus Blackman, 1928. New York St. Coll. For., Syracuse, Tech. Pub. 25:32 (Holotype, female; Glacier National Park. Montana; U.S. Nat. Mus.. 41267)
Pityophthorus smithi Schedl, 1931. Canadian Ent. 63:163 (Holotype. female; Copper Mountain, British Columbia: Canadian Nat. Coll.. 3168): Wood, 1977, Great Basin Nat. 37:515. Synonymy
Diagnosis.- This species is distinguished from indigus Wood by the much more coarsely punctured elytral dise, by the very slightly deeper declivital sulcus with the lateral granules very slightly larger, and by the more abundant, longer elytral vestiture.

Female.- Length $2.0-2.2 \mathrm{~mm}, 2.6$ times as long as wide; color very dark brown.

Frons as in indigus except very slightly less strongly convex, punctures slightly smaller, slightly closer, vestiture slightly longer, slightly more abundant.

Pronotum as in indigus.
Elytral dise about as in indigus except impressed points obsolete, strial punctures
slightly larger, interstriae 1 and 3 each with about eight punctures only slightly smaller than those of striae; declivity as in indigus except very slightly steeper, sulcus very slightly deeper, tubercles on interstriae 3 very slightly larger, interstrial setae slightly longer and more consistently present on sides and declivital interstriae 1 and 3, length of longest setae equal to two-thirds width of a discal interstriae.

Male.- Similar to female except frons with a very weak to moderate median carina on lower half.

Distribution.-British Columbia to Montana.

CANADA: British Columbia: Copper Mt., 29-X-29, I8-III-30, P. contorta, G. S. Smith. USA: Montana: Glacier N.P., Hopk. 16968a, reared, 30-VIII-23, Pinus contorta, J. C. Evenden.

Notes. - The above treatment was based on the holotypes of fuscus and smithi and on 16 other specimens.

## 57. Pityophthorus alpinensis G. Hopping Fig. 205

Pityophthorus alpinensis G. Hopping, 1960, Canadian Ent. 92:865 (Holotype, female: Highwood Pass, Alberta; Canadian Nat. Coll., 7291)
Diagnosis.- This species is distinguished from toralis Wood by the much more finely punctured female frons, by the more gradually impressed male frons on its lower half, by the more strongly elevated male frontal carina, with its crest longitudinally convex, and by the hosts.

Female.- Length 2.3-2.7 mm, 2.7 times as long as wide; color almost black.

Frons as in toralis except more extensively, more distinctly concave; surface dull, punctures usually finer, more widely spaced, interspaces about one to three times diameter of a puncture (less than diameter of a puncture in toralis), setae usually more abundant, longer, longest setae equal in length to more than half distance between eyes (equal to one-third, rarely one-half in toralis).

Pronotum and elytra as in toralis except declivital interstriae 3 usually more distinctly punctured.

Male.-Similar to female except frons; frons similar to male toralis except lower half much less strongly impressed, crest of carina longitudinally convex, surface smoother,
more finely punctured (differences most conspicuous in area of distributional sympatry).

Distribution.- Alberta to Idaho.
CANADA: Alberta: Sunshine Lodge, Banff N.P., I-VI60, Larix lyallii, 59A1247-0I, G. R. Hopping; Highwood Pass, 24-IX-56; Seebe, I-X-65. USA: 1daho: Salmon Mountain, Bitterroot N.F.. 8-VIII-74, L. lyallii, Hopk. 58695-A, M. M. Furniss.

## Host.- Larix lyallii.

Biology.- Reared from a broken top.
Notes. - The above treatment was based on the holotype and on 102 other specimens. Bright (1977:516) treated this species as a synonym of nitidus Swaine; however, this species has the even-numbered discal interstriae punctured, differences in the frons of both sexes, and other minute differences.

## 58. Pityophthorus toralis Wood

Pityophthorus toralis Wood, 1964, Great Basin Nat. 24:59 (Holotype, female; Beaver Creek, Logan Canyon, Utah; Wood Coll.)

Fig. 205. Pityophthorus alpinensis: I, dorsal aspect of female; 2, antenna; 3, head of male; 4, head of female. (After G. Hopping 1960:866.)

Mycloborus confusus Bright, 1966, Pan Pacific Ent. 42:295 (Holotype, female; Mt. Tallac, Eldorado Co., California; Ohio State Univ. Coll.); Bright and Stark, 1973, Bull. California Ins. Surv. 16:I05. Synonymy
Pityophthorus collinus Bright, 1968, Canadian Ent. 100:605 (Holotype, female; Terrace Mountain, 15 miles W Nahun, Osoyoos District, British Columbia; Canadian Nat. Coll.); Bright, 1977, Canadian Eut. 109:518. Synonymy
Diagnosis.- This species is distinguished from nitidus Swaine as indicated in the diagnosis of that species and, in addition, by the longitudinally concave crest of the male carina. It is distinguished from alpinensis G. Hopping as indicated in the diagnosis of that species.

Female.- Length 2.1-2.7 mm, 2.7 times as long as wide; color very dark brown, almost black.

Frons impressed from eye to eye, from epistoma to well above eyes, shallowly concave on central half, ascending slightly toward epistoma; margins abruptly angled near eyes; surface shining, densely, closely, rather coarsely punctured, punctures separated by distances less than diameter of a puncture in central area; vestiture of fine, rather short hair in central area, of subplumose, very long setae on lateral and dorsal margins, longest setae at least equal in length to one-third distance between eyes.

Pronotum as in scalptor Blackman except punctures on discal area armed on their lateral margins by granules often as large or larger in diameter than adjacent puncture. Discal area with moderately abundant, semirecumbent hair.

Elytral disc as in mitidus except interstriae 2 and 4 with punctures on posterior third or more. Declivity as in nitidus except sulcus slightly deeper, granules slightly larger, punctures on interstriae 1 and 2 usually obsolete (minute punctures sometimes present).

Male.-Similar to female except upper frons strongly convex, lower third occupied by a rather strong, transverse impression, surface very coarsely, closely, deeply, almost subgranulately punctured, median carina on lower two-thirds of area below upper margins of eyes, its longitudinal crest concave, rather weakly developed above impressed area.

Distribution.-Alberta and British Columbia to California and Utah.

CANADA: Alberta: Burmis, Calgary, Cowley. British Columbia: Anahim Lake, Terrace Mountain near Nahum. USA: California: Ebbetts Pass in Alpine Co., Mt. Tallac in Eldorado Co., Onion Valley, Yosemite N.P. Idaho: Salmon Mountain in Bitterroot N.F. Oregon: Hood River. Utah: Logan Canyon. Wyoming: Laramie.

Hosts.-Pinus albicaulis, P. contorta (rare), P. flexilis.

Biology.- Specimens were taken from the phloem of branches about $2-3 \mathrm{~cm}$ in diameter.

Notes.- The above treatment was based on the holotypes of toralis, confusus, and collinus and on 173 other specimens.

Three specimens from 13 miles N and 12 miles E Dolores, Colorado, from Picea engelmannii, and one male from 9 miles SE Aspen, Colorado, from Abies lasiocarpa, are tentatively assigned to this species. The females of the former and the latter male are typical of toralis; the male frons of the former is more nearly like nitidus. Obviously, much more remains to be learned about this complex of species.

## 59. Pityophthorus litos Bright

Pityophthorus litos Bright, 1976, Great Basin Nat. 36:4:35 (Holotype, female; 25 miles or $40 \mathrm{~km} W$ Orizaba, Veracruz, Mexico; Canadian Nat. Coll.)
Diagnosis.- Apparently allied to glabratulus (Schedl), but it is distinguished by the different frons and declivity as described below.

Female.- Length 1.5-1.6 mm, 2.6 times as long as wide; color dark brown.

Frons plano-convex on central two-thirds; surface shining, moderately, rather finely punctured; frontal vestiture moderately sparse, rather short in central area, long on margins, longest setae equal in length to half distance between eyes.

Pronotum about as in glabratulus except six serrations on anterior margin much smaller and discal area smooth, shining, with a few impressed points.

Elytral disc much as in glabratulus except surface more nearly reticulate, declivital interstriae 2 ascending rather strongly from striae 1, interstriae 3 more broadly rounded, setae on declivital interstriae 3 much longer.

Male. - Male similar to female except frons rather strongly convex, coarsely, closely punctured, a low, sometimes obscure median
carina from epistomal margin half distance to upper level of eyes.

Distribution.- Veracruz.
MEXICO: Veracruz: 40 km W Orizaba, 29-IV-69, Pinus, D. E. Bright.

Notes.- The above treatment was based on the type series of eight specimens.

## 60. Pityophthorus sapineus Bright

Pityophthorus sapineus Bright, 1981, Ent. Soc. Canada Mem. 118:194 (Holotype, female; Atenquique, Jalisco, Mexico: Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from litos Bright by the very different frons and declivity, as described below, and by the much finer discal striae.

Female.- Length $1.7-1.8 \mathrm{~mm}, 2.6$ times as long as wide; color very dark brown.

Frons broadly flattened to well above eyes, with centra! third weakly, subconcavely impressed; surface smooth, shining, uniformly, finely punctured, width of interspaces about one to two diameters of a puncture; vestiture of a rather dense marginal fringe of very long setae, longest setae equal in length to half distance between eyes, much shorter in central area.

Pronotum and elytra as in litos except strial punctures smaller, strial vestiture shorter, interstrial setae obsolete on 8 , several setae present on 9 .

Male.-Similar to female except frons broadly convex, a distinct transverse impression on lower third, shining, coarsely punctured, carina absent, vestiture short, sparse, inconspicuous; declivity with four interstrial setae of moderate length on 3 , three on 8 , and several on 9.

Distribution.- Jalisco.
MEXICO: Jalisco: Atenquique, Pinus.
Notes.- The above treatment was based on four paratypes.

## 61. Pityophthorus glabratulus (Schedl)

Ctenyophthorus glabratulus Schedl, 1955 (1956), Zeitschr. angew. Ent. 38:26 (Lectotype, female; Quezaltenango, Guatemala; Schedl Coll., designated by Bright, 1976, Coleopt. Bull. 30:186)
Neodryocoetes glabratulus: Schedl, 1963, Ent. Arb. Mus. Frey 14:162
Pityophthorus glabratulus: Bright, 1976, Coleopt. Bull. 30:186
Diagnosis.- This species is distinguished from diglyphus Blandford by the smaller size,
by the minutely punctured female frons, with less abundant, shorter vestiture, by the more evenly convex male frons, with the carina not dentate, more strongly elevated on dorsal half, and by the short declivital setae.

Female.- Length $1.7-2.1 \mathrm{~mm}, 2.6$ times as long as wide; color very dark brown.

Frons plano-convex from epistoma to well above eyes, lateral margins extending to three diameters of a facet from margin to eye, epistoma slightly raised; surface smooth, shining, central two-thirds rather sparsely, minutely punctured, punctures slightly larger toward margins; vestiture of fine, rather sparse, yellow hair of moderate length, distinctly longer at margins, longest setae equal to less than half distance between eyes. Antennal club with suture 1 moderately procurved and septate, 2 rather strongly procurved, slightly septate at extreme margins, not attaining middle of club.

Pronotum 1.06 times as long as wide; widest on basal third, sides feebly arcuate on basal half, distinctly constricted on anterior half, rather broadly rounded in front; anterior margin armed by 10 serrations, slightly larger toward middle; summit slightly anterior to middle, a distinct transverse impression behind summit; posterior areas almost smooth to rather strongly reticulate, punctures rather fine, not round, median line broadly impunctate. Vestiture of fine, short hair.

Elytra 1.6 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed except 1 slightly near declivity, punctures moderately course, rows becoming slightly irregular on basal fourth; interstriae almost smooth, shining, odd-numbered with sparse punctures similar to those of striae, 2 and 4 impunctate. Declivity steep, narrowly, rather shallowly bisulcate; punctures on striae 1 and 2 impressed, half as large as on disc; interstriae 1 distinctly elevated, armed by a row of fine granules, 2 as wide as 1, flat, smooth, impunctate, 3 rather abruptly, modestly elevated, slightly higher than 1 , elevation extended to junction with 8 and on apex of 8,3 armed by a row of $8-10$ small granules. Vestiture of minute strial and short, sparse interstrial hair, almost obsolete on disc, not longer on declivity.

Male.- Similar to female except frons slightly more strongly convex, punctures slightly larger, closer, median carina extending from slightly above epistoma to slightly above eyes, its longitudinal crest evenly convex, its greatest height at upper level of eyes; serrations on anterior margin of pronotum larger.

Distribution.- Oaxaca to Guatemala.
MEXICO: Chiapas: 13 km E San Cristóbal, 6-VI-69. Pinus ayacauite, P. ochoternal, D. E. Bright. Oaxaca: 51 km SE Nochixtlán, 14-VII-69, P. pringlei, D. E. Bright. GUATEMALA: Guatemala City, $30-\mathrm{V}-64,1300 \mathrm{~m}$, No. 650. P. pseudostrobus, S. L. Wood; Quezaltenango, 26V.64. 1600 m , No. 622, P. pseudostrobus S. L. Wood.

## 62. Pityophthorus ineditus Bright

Pityophthorus ineditus Bright, 1976, Great Basin Nat. 36: 434 (Holotype, female; 32 miles or 51 km S Valle Nacional, Oaxaca, Mexico; Canadian Nat. Coll., 15084)
Diagnosis.- This species is distinguished from diglyphus Blandford and leiophyllae Blackman by the absence or near absence of a median carina in the male and by the very different declivity.

Female.- Length $1.7-2.0 \mathrm{~mm}, 2.6$ times as long as wide; color dark brown.

Frons broadly plano-convex to well above eyes except plano-concave on central third; surface smooth, very brightly shining, punctures small, very sparse; vestiture sparse, moderately long in central area, very long on margins, much longer than in diglyphus or leiophyllae.

Pronotum and elytra as in diglyphus except for declivity. Declivity convex, steep; striae 1 strongly impressed, 2 not impressed, punctures reduced; interstriae 1 distinctly elevated, armed by a row of fine granules, 2 as wide as 1 or 3 , ascending laterally, 3 broadly rounded, armed by about three rather coarse tubercles. Vestiture largely confined to declivital interstriae, short on 1 , absent on 2,4 , and 6 , very long on 3 , moderately long on 5 and 7.

Male.-Similar to female except frons rather strongly, transversely impressed from epistoma to upper level of eyes, smooth, shining, punctures fine, sparse, vestiture in impressed area rather abundant, moderately long, carina very short, near epistoma, or absent; tubercles on declivity much smaller.
Distribution.- Oaxaca to Veracruz.

MEXICO: Oaxaca: 51 km S Valle Nacional, 21-V-71, Pinus, D. E. Bright. Veracruz: Las Vigas, 5-VII-67, No. 156, Pinus branches, S. L. Wood; 11 km SE Las Vigas, 15-XII-48, H. B. Leech.

Notes.- The above treatment was based on the type series of 35 specimens.

## 63. Pityophthorus leiophyllae Blackman Fig. 200

Pityophthorus leiophyllae Blackman, 1942, Proc. U.S. Nat. Mus. 92:205 (Holotype, female; Chalco, Mexico, Mexico; U.S. Nat. Mus., 55981)
Pityophthorus auctor Blackman. 1942, Proc. U.S. Nat. Mus. 92:214 (Holotype, female; Perote, Veracruz, Mexico; U.S. National Mus., 55988); Bright, 1977. Canadian Ent. 109:514. Synonymy
Diagnosis.- This species is distinguished from diglyphus Blandford by the subreticulate surfaces of the pronotum and elytra, by the conspicuous median glabrous line from epistoma to vertex on the female frons, by the less strongly impressed male frons with the carina much higher, and by the short declivital setae.

Female.- Length $1.9-2.3 \mathrm{~mm}, 2.6$ times as long as wide; color very dark reddish brown, elytra usually at least partly lighter.

Frons as in glabratulus (Schedl) except median sixth from epistoma to vertex impunctate and glabrous; vestiture as in glabratulus except absent on median sixth.

Pronotum and elytra as in glabratulus and diglyphus except surfaces on both subreticulate to reticulate, punctures on both slightly larger. Vestiture on declivity as on disc and sides, not longer.

Male.-Similar to female except surface reticulate, coarsely punctured, distinctly, shallowly, abruptly impressed below upper level of eyes, a very strong, subdentate, laterally compressed carina on central two-thirds of median line between epistoma and upper level of eyes.

Distribution.- Michoacán to Veracruz and Oaxaca.

MEXICO: Hidalgo: 6 km E Zacatlan, 12-VI-67, 2500 m, No. 18, Pinus, S. L. Wood. Mexico: Km 20 Texcoco. 5-II-62, Pinus, R. Coronado. Michoacán: Parácuraro, I0-1X-61, Pinus, R. Coronado. Oaxaca: 41 km SE Nochixtlán, 17-VI-67, No. 56, Pinus, S. L. Wood. Veracruz: Las Vigas, 5-VII-67, No. 157, Pinus, S. L. Wood.

## Hosts. - Pinus sp.

Biology.- Specimens were taken from twigs and small branches.

Notes. - The above treatment was based on the holotypes of leiophyllae and auctor and on three other specimens. Bright (1977:514) placed this species under diglyphus Blandford; however, the two are quite different.

## 64. Pityophthorus diglyphus Blandford

Pityophthorus diglyphus Blandford. 1904, Biol. Centr. Amer.. Coleopt. 4(6):240 (Syntypes; Quiché Mts. and Balheu in Verapaz, Guatemala; British Mus. Nat. Hist.)
Diagnosis. - This species is distinguished from glabratulus (Schedl) by the more coarsely punctured female frons, with longer more abundant vestiture, by the impressed male frons, with a dentate carina, and by the very long, fine, declivital setae.

Female. - Length 2.3-2.5 mm, 2.6 times as long as wide; color very dark brown.

Frons plano-convex, as in glabratulus except punctures moderately coarse, not larger toward margins, vestiture more abundant, much longer at margins; margin of flattened area separated from margin of eye by distance equal to diameter of one facet.

Pronotum as in glabratulus except rarely with any reticulation, punctures distinctly larger.

Elytra as in glabratulus.
Male.- Similar to female except frons abruptly, moderately impressed below upper level of eyes, carina dentate, at center of lower half, a weak (longitudinally concave) crest extending to above upper level of impressed area.
Distribution.-Guatemala.
GUATEmalA: San Cristóbal in Huehuetenango, 28-V-64, 2300 m, No. 632, Pinus pseudostrobus, S. L. Wood; Balheu and Quiché Mountains in Verapaz.

Host. - Pinus pseudostrobus.
Biology. - Specimens were taken from twigs 1 cm in diameter.

Notes. - The above treatment was based on Blandford's 4 syntypes and on 10 other specimens.

## 65. Pityophthorus vespertinus Bright

Pityophthorus vespertimus Bright, 1978, Great Basin Nat. 38:83 (Holotype, female; 37 km or 23 miles $W$ Durango, Durango, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished from diglyphus Blandford by the smaller size,
by the reticulate or subreticulate pronotal disc, and by the short declivital setae.

Female.- Length $1.7-1.8 \mathrm{~mm}, 2.5$ times as long as wide; color dark brown.

Frons as in diglyphus except punctures slightly smaller, more numerous, more evenly distributed, vestiture finer, shorter.

Pronotum essentially as in diglyphus except posterior areas reticulate.

Elytra as in diglyphus except declivity slightly steeper, less strongly sulcate, setae all short, none longer than distance equal to width of one interstriae (mostly less than onefourth this distance).

Distribution.- Durango.
MEXICO: Durango: 37 km W Durango, 4-VI-65, 2000 m . No. 6, Pinus, S. L. Wood.

Notes. - The above treatment was based on the type series of four specimens.

## 66. Pityophthorus rudis Blackman

 Fig. 200Pityophthorus rudis Blackman, 1942, Proc. U.S. Nat. Mus. 92:212 (Holotype, female; Amecameca, Distrito Federal, Mexico; U.S. Nat. Mus., 55987)
Diagnosis.- This species is distinguished by the moderately large size, slender form, impunctate interstriae, reticulate elytral surface, and the very long declivital setae.

Female. - Length 2.3-2.7 mm, 2.8 times as long as wide; color dark reddish brown.

Frons broadly flattened, plano-concave on median half below upper level of eyes; surface smooth, shining, punctures moderately coarse, rather close in marginal areas, almost impunctate on median sixth of lower half; vestiture sparse but moderately long in central area, a rather dense row on margins, longest setae equal in length to two-thirds distance between eyes.

Pronotum 1.0 times as long as wide; as in diglyphus Blandford except dise more nearly reticulate.

Elytra 1.9 times as long as wide, 2.1 times as long as pronotum; sides almost straight and parallel on basal three-fourths, rather broadly rounded behind; striae not impressed except 1 near declivity, punctures in rows, moderately coarse, deep; interstriae about one and one-half times as wide as striae, surface subreticulate, shining, impunctate except near declivity and on 1 to middle of disc. Declivity steep, rather strongly sulcate; striae 1 obsolete, 2 rather finely, shallowly punctured;
interstriae 1 slightly elevated, armed by a few very minute granules, 2 rather strongly impressed, three times as wide as 1 , ascending on lateral third to striae 2,3 rather strongly elevated and armed by 6-8 coarse tubercles, much higher than suture (much like durus Blackman, but not nearly as steep). Vestiture largely confined to declivity on interstriae 3 and lateral areas; consisting of very long hair on odd-numbered interstriae, longest equal in length to distance from suture to discal striae 4.

Male.-Similar to female except frons as in male diglyphus Blandford.

Distribution.- Mexico.
MEXICO: Mexico: Amecameca, 2S-1-36, Pinus, 669. D. DeLeon.

Notes.- The above treatment was based on the holotype, allotype, and seven paratypes.

## 67. Pityophthorus venustus Blackman

Pityophthorus cenustus Blackman. 192s, New York St. Coll. For., Syracuse, Tech. Pul). 25:75 (Holotype, female: Kabab National Forest. Arizona: ('.S. Nat. Mus., 41290)
Pityophthorus artifex Blackman, 1928, New York St Coll. For., Syracuse, Tech. Pub. 25:76 (Holotype. female: Mevers, California; U.S. Nat. Mus. 41291): Bright. 1977. Canadian Ent. 109:51s Synonymy
Diagnosis.- This species is distinguished from the diglyphus group of species by the absence of an elevation toward the apex of declivital interstriae 3 and 8 , and by the presence of tubercles at the base of declivital interstriae 2.

Female.- Length 1.7-2.1 mm, 2.8 times as long as wide; color very dark brown.

Frons plano-convex from epistoma to well above eyes, lateral margins abruptly subangulate, separated from margin of eye by distance equal to diameter of one facet; surface smooth, shining, uniformly, closely, rather coarsely punctured; vestiture uniformly distributed, rather long, slightly longer at margins, longest setae equal in length to about half distance between eves. Antennal club rather similar to glabratulus (Schedl).

Pronotum 1.03 times as long as wide; outline as in glabratulus except anterior margin slightly more narrowly rounded; posterior areas smooth, shining, punctures round,
rather coarse, deep, close. Vestiture of fine, short hair.

Elytra 1.8 times as long as wide, 1.8 times as long as pronotum; sides almost straight and parallel on basal three-fourths, rather broadly rounded behind; striae not impressed except 1 near declivity, punctures rather coarse, close, deep, in rows except partly confused on basai fifth; interstriae slightly wider than striae, surface subreticulate, shining, punctures irregularly spaced, often absent on 2 and 4 , subequal in size with those of striae, often confused with them, basal area near scutellum usually wrinkled. Declivity steep, rather shallowly, narrowly sulcate; striae 1 and 2 finely, distinctly punctured; interstriae 1 abruptly, rather weakly elevated, 2 impressed, as wide as 1, smooth, shining, impunctate except a row of about four fine granules at base, 3 gradually, moderately elevated on upper two-thirds, much higher than 1 , armed by a row of 8 - 10 fine tubercles. Vestiture of fine, short hair on dise and declivity, slightly longer on sides.

Male.- Similar to female except frons more strongly convex, shining, coarsely punctured, median carina from epistoma to above eyes sharply, moderately to very strongly elevated, highest on lower third; serrations on anterior margin of pronotum usually larger.

Distribution.- British Columbia and South Dakota to California and W Texas.
CANADA: British Columbia: Creston. USA: Arizona: Chiricahua Mts., Huachuca Ms., Kaibab N.F., Pinalino Mts., Santa Catalina Mts., Williams. California: Blancós Corral in White Mts. of Mono Co.. Carrville, Hat Creek, Julian. Junipero Serra Peak in Monterrey Co., Lake Arrowhead, Lake Tahoe, Meyers, Mill Creek Camp near Strawberry, Mt. Laguna, Mt. Palomar. Colorado: Breckenridge, Longmont. Idaho: Clarkis. Nebraska: Halsev, Norden. New Mexico: Lake Roberts. South Dakota: Black Hills. Texas: Guadeloupe Mts. N.P. in Culberson Co. Utah: Kamas, La Sal Mts.

Hosts.- Pinus aristata, P. contorta, $P$. coulteri, P. jeffreyi, P. leiophylla, P. monticola, P. ponderosa, P. strobiformis.

Biology.- Specimens were taken from small branches.

Notes.- The above treatment was based on the holotypes of venustus and artifex and on 110 other specimens.

## 68. Pityophthorus durus Blackman

Pityophthorus durus Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Pub. 25:70 (Holotype, female; Paradise, Arizona; U.S. Nat. Mus., 41287)
Diagnosis.- This variable species is usually distinguished by the rather large, stout body, by the weakly to moderately confused, coarse elytral punctures, by the variable male median carina, and by the deeply sulcate, very steep, distinctive elytral declivity.

Female.- Length $1.9-2.6 \mathrm{~mm}, 2.5-2.6$ times as long as wide; color dark reddish brown.

Frons flat to plano-convex from epistoma to well above upper level of eyes, lateral margins abruptly subangulate, slightly more than diameter of one facet from margin of eye; surface shining, closely, deeply, rather finely punctured, punctures spaced by about one to two diameters of a puncture, uniformly distributed; vestiture rather abundant, moderately long, distinctly longer at margins, longest setae almost equal to half distance between eyes. Antennal club comparatively small, 1.2 times as long as wide, suture 1 weakly, 2 moderately procurved, 2 extending slightly beyond middle of club.

Pronotum 1.03 times as long as wide; widest at base, rather weakly arcuate on slightly more than basal half, then distinctly constricted, rather narrowly rounded in front; anterior margin armed by $8-10$ serrations, median ones distinctly larger; summit at middle, a distinct transverse impression behind summit; posterior areas smooth, shining, with numerous impressed points, punctures rather coarse, deep, moderately close. Vestiture of fine, rather short hair.

Elytra 1.5 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal three-fourths, very broadly rounded behind; striae not impressed except 1 near declivity, punctures coarse, deep, close, varying from definite rows to moderately confused; interstriae almost smooth, shining, as wide as striae, somewhat regularly punctured (often almost impunctate on 2 and 4), punctures fine to entirely confused with those of striae. Declivity very steep, strongly bisulcate; punctures on striae 1 and 2 less than half as large as on disc to very small; interstriae 1 distinctly elevated, almost half as
wide, varying from unarmed to a row of fine tubercles, 2 slightly wider than 1, almost flat from striae 1 to 2 , armed at base by about three small tubercles, 3 strongly elevated on upper two-thirds, much higher than 1 , summit rounded to lateral areas, armed by $8-10$ rather coarse tubercles. Vestiture of minute strial hair and longer interstrial hair; interstrial setae on dise sparse, rather short, long and coarse on lateral elevations of declivity and vicinity.

Male. - Similar to female except frons broadly convex (slightly impressed in occasional specimens), shining, closely, rather coarsely punctured, vestiture inconspicuous, short, either entirely without a carina or with a variable low median carina of uniform height from epistoma to vertex; serrations on anterior margins of pronotum usually larger.

Distribution.- Arizona to Oaxaca.
USA: Arizona: Chiricahua Mts., Paradise, Santa Rita Mts. MEXICO: Chihuahua: La Laja. Durango: El Salto, 16, 38, and 96 km W Durango. Hidalgo: Durango, Jacala, Tulancingo. Mexico: Chalco. Michoacán: Carapan, 25 km E Morelia, Quiroga, Volcan Parícutin. Mexico: Cuemavaca. Oaxaca: Nochixtlán, Oaxaca. Puebla: Texmelucan. Veracruz: Las Vigas.

Hosts.-Pinus leiophylla, P. strobiformis, P. spp.

Biology.- Specimens were taken from limbs and branches.

Notes.- The above treatment was based on the holotype and on 143 other specimens.

## 69. Pityophthorus laticeps Bright

Pityophthorus laticcps Bright, 1978, Great Basin Nat. 38:78. (Holotype, male; 20.5 km N Oaxaca, Oaxaca, Mexico; Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from ciliatus Blackman by the larger size, by the smoother pronotum and elytra, by the longer female frontal vestiture, and by the very different elytral declivity.

Female.- Length 2.1-2.8 mm, 2.8 times as long as wide; color dark brown.

Frons as in ciliatus except more uniformly, perhaps more closely punctured, vestiture distinctly longer, longest setae equal to 0.67 times distance between eyes ( 0.4 in ciliatus).

Pronotum and elytra about as in ciliatus except surfaces smoother, all discal interstriae sparsely punctured, declivity not as steep, slightly more broadly sulcate, lower third somewhat more nearly flattened.

Male- - Similar to female except frons as in male ciliatus (including a long, feebly elevated median carina); upper half of declivity very similar to male ciliatus, lower half with areas lateral to interstriae 3 much more broadly rounded (subinflated), lower third somewhat broadly flattened (much more conspicuously than in female).

Distribution.- Oaxaca.
MEXICO: Oaxaca: 20.5 km N Oaxaca, 6-VI-71, 3000 m. Pinus, D. E. Bright.

Notes.- The above treatment was based on the holotype and allotype.

## 70. Pityophthorus orarius Bright

Pityophthorus orarius Bright, 1968, Canadian Ent. 100:607 (Holotype, female: Colwood, Esquimalt District, British Columbia; Canadian Nat. Coll., $9735)$
Diagnos1s.- This species is distinguished by the irregularly convex female frons, with short, sparse vestiture, by the reticulate-granulate pronotal disc, and by the distinctive elytra. It is unique and cannot be associated with any species group.

Female.- Length $2.0-2.2 \mathrm{~mm}, 2.7$ times as long as wide; color black.

Frons convex above eyes, lower area transversely, broadly convex, longitudinally, shallowly concave on central half, epistomal area slightly elevated, a distinct, low, subcarinate, median tubercle immediately above epistomal margin; surface shining, with impressed points, punctures fine, moderately abundant, spaced by one to three diameters of a puncture; vestiture short, rather sparse, longest equal to about one-tenth distance between eyes.

Pronotum 1.08 times as long as wide; widest on basal third, sides on basal half feebly arcuate, converging very slightly, constriction on anterior half indistinct, rather broadly rounded in front; anterior margin armed by 12 low serrations; summit in front of middle, transverse impression behind summit distinct; posterior areas reticulate-subgranulate, punctures close, rather coarse, deep, spaced by distances equal to less than half diameter of a puncture. Vestiture short, suberect, moderately abundant.

Elytra 1.7 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal two-thirds, broadly rounded
behind on median half; striae not impressed except 1 weakly, punctures moderately coarse, close, deep, in slightly irregular rows; interstriae about twice as wide as striae, almost smooth, shining, punctures slightly smaller than those of striae, irregularly spaced on all interstriae. Declivity steep, rather broadly convex; striae 1 and 2 minutely, distinctly, regularly punctured; interstriae 1 rather narrowly, distinctly elevated, armed by a row of fine granules, 2 shallowly, broadly sulcate, three times as wide as 1 , almost smooth, with obscure points and indefinite lines, 3 feebly elevated, armed by a row of fine, rounded granules. Vestiture of moderately abundant, minute, erect, strial hair and slightly longer interstrial hair on disc and declivity, except absent on declivital interstriae 2 , not longer on declivity.

Male.-Similar to female except frons less strongly impressed, more coarsely punctured, with an acutely, rather strongly elevated median carina from epistoma to upper level of eyes, highest on lower half.

Distribution.- British Columbia.
CANADA: British Columbia: Colwood, Esquimalt District, 9-I-68, Douglas fir twigs, D. Ruth, also 28-VII65, A. F. Hedlin; Langley, 22-IV-59, Douglas fir twigs, K. Graham.

Host.-Pseudotsuga menziesii.
Notes. - The above treatment was based on the holotype, on 39 paratypes, and on 6 other specimens.

## 71. Pityophthorus recens Bright

Pityophthorus recens Bright, 1977, Great Basin Nat. 36:438 (Holotype, female; Pine Pass. British Columbia: Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from fuscus Blackman by the very different frons and pronotal dise as described below.

Female.- Length $1.8-2.0 \mathrm{~mm}, 2.8$ times as long as wide; color dark reddish brown.

Frons strongly convex, densely, finely punctured, and glabrous much as in some nitidus Swaine.
Pronotum about as in nitidus except discal punctures not armed by tubercles or granules.

Elytra as in fuscus except smoother, more brightly shining.

Male. - Similar to female except frons more coarsely punctured, a short, very weak median carina on lower fifth.

Distribution.- British Columbia.
CANADA: British Columbia: Pine Pass, 11-VII-72. Picea, D. E. Bright.

Notes.- The above treatment was based on the type series of eight specimens.

## 72. Pityophthorus amoenus Blandford

Pityophthorus amoenus Blandford, 1904, Biol. Centr. Amer., Coleop. 4(6):237 (Holotype, female; Dueñas, Guatemala; British Mus. Nat. Hist.)
Diagnosis.- This species is distinguished by the rather short, uniformly distributed female frontal vestiture, by the reticulate pronotal disc, by the absence of interstrial punctures on the elytral disc except on 2 near declivity, and by the moderately impressed declivital sulcus with tubercles on 1 and 3. It is apparently allied to declivisetosus Bright.

Female.- Length $2.0 \mathrm{~mm}, 2.7$ times as long as wide; color yellowish brown.

Frons weakly convex on a rather narrow area, slightly, transversely impressed on middle half, margins separated from eye by at least four diameters of a facet; surface shining, closely, rather coarsely punctured; vestiture uniformly distributed. moderately abundant, of almost uniform length, setae about equal in length to one-fifth distance between eyes. Antennal club 1.7 times as long as wide; suture 1 straight, mostly septate, 2 feebly procurved, evidently septate only at margins.

Pronotum 1.07 times as long as wide; widest at base, sides very feebly arcuate and converging very slightly on basal half; anterior margin broadly rounded, armed by 14 low, subcontiguous serrations; summit at middle; serrations on anterior slope somewhat concentric (at least laterally); posterior areas mostly reticulate, punctures rather coarse, not close; impressed points not evident. Discal area glabrous.

Elytra about 1.7 times as long as wide (half of right elytron missing from type), 1.7 times as long as pronotum; sides almost straight and parallel on basal three-fourths, then broadly rounded, obtusely pointed at apex (not at all acuminate); disc shining, almost smooth; striae 1 weakly, others not impressed, punctures coarse, close, deep; interstriae slightly wider than striae, 1-4 with a few punctures on posterior fourth, 2 with three fine granules at base of declivity. Declivity steep,
moderately bisulcate; striae 1 and 2 punctured to apex, punctures less than half as large as on disc; interstriae 1 distinctly elevated, armed by about eight rather small, pointed tubercles, 2 rather strongly impressed, smooth, shining, impunctate, almost three times as wide as 1 , ascending laterally, lateral areas very slightly higher than suture, 3 armed by four tubercles slightly larger than those on 1. Vestiture confined to declivity, rows on all interstriae except 2 on face, rather coarse and long, half as long on 1 .

Distribution.- Guatemala.
Guatemala: Dueñas (6-8 km SW Antigua), G. C. Champion.

Notes.- The above treatment was based on the holotype.

This unique species appears to combine the characters of several widely separated groups. Superficially it more nearly resembles nigricans Blandford, but it may not be closely related.

## 73. Pityophthorus declivisetosus Bright

Pityophthorus declicisetosus Bright, 1977. Canadian Ent. 109:525 (Holotype, female; 51 km or 32 miles SE Nochixtlán, Oaxaca, Mexico; Canadian Nat. Coll.)
Diagnosis.- This unique species is characterized by the frontal and declivital characters cited below, particularly by the coarse declivital setae on the female.

Female.- Length 1.4-1.7 mm, 2.4 times as long as wide; color dark brown.

Frons very weakly convex to upper level of eyes, margins rounded; surface smooth, shining, punctures fine to rather coarse, rather shallow; vestiture sparse, rather short, uniformly distributed.

Pronotum essentially as in venustus, posterior areas subreticulate, punctures rather coarse, deep.

Elytra 1.5 times as long as wide; sides straight and parallel on basal half, distinctly narrowed, then broadly rounded behind; striae not impressed, punctures rather coarse, deep, in slightly irregular rows; interstriae obscurely subreticulate, shining, distinctly wider than striae, punctures sparse, similar to those of striae. Declivity steep, rather strongly, broadly sulcate; punctures on striae 1 and 2 reduced, distinct; interstriae slightly elevated, fine punctures obscure, 2 twice as
wide as 1 , ascending slightly laterally, 3 distinctly higher than 1, summit abrupt, armed by about eight rather coarse tubercles, 1 and 3 with a few smaller tubercles near base. Vestiture of minute strial setae and interstrial setae; interstrial setae fine and rather short on disc, those on declivity long and very coarse, small ou 1 , absent on 2 .

Male.-Similar to female except frons distinctly convex, more coarsely punctured, a weak median carina on lower half; vestiture on declivity fine and shorter, as on disc.

Distribution.- Oaxaca to Veracruz.
MEXICO: Oaxaca: 41 km SE Nochixtlan, $17-\mathrm{V} 1-67$. No. 56 . Pinus, S. L. Wood; 51 km SE Nochixtlán, J4-VII69, P. pringlei, D. E. Bright.

Notes. - The above treatment was based on the type series of 31 specimens.

## 74. Pityophthorus tumidus Blackman

Pityophthorus tumidus Blackman. 192S. New York St. Coll. For., Syracuse, Tech. Pub. 25:58 Holotype. female: Eureka, California: U.S. Nat. Mus.. 41282)

Diagnosis.- This species is distinguished by the absence of female frontal setae and a strong male frontal carina, by the rather long strial hair, by the impunctate discal interstriae, and by the steep, unique declivity.

Female.- Length 2.1-2.2 mm, 2.8 times as long as wide: color brown.

Frons rather weakly convex to slightly above upper level of eyes; surface smooth, shining, punctures rather coarse, shallow, moderately close; vestiture short, sparse, inconspicuous, length of longest setae about equal to three diameters of a facet.

Pronotum 1.02 times as long as wide: outline about as in toralis Wood; posterior area coarsely, deeply, very closely punctured, interspaces equal to about one-third diameter of a puncture, some obscure subreticulation evident in and between punctures. Vestiture fine, short.

Elytra 1.8 times as long as wide, 1.7 times as long as pronotum; sides almost straight and parallel on basal three-fourths, broadly rounded behind; striae 1 weakly, others not impressed, punctures in definite rows, rather coarse; interstriae one and one-half times as wide as striae, shining, almost smooth, impunctate except 1 and 3 each with about two
punctures on posterior half. Declivity on posterior fourth, very steep, shallowly bisulcate; striae 1 impressed, 1 and 2 distinctly, rather finely punctured, those on 3 each with a minute granule on rim; interstriae 1 moderately elevated, with a row of very fine granules, 2 twice as wide as 1 , moderately impressed on mediau side, gradually ascending laterally, 3 rounded, not quite as high as 1 , with about six small, setiferous granules. Strial setae extend to base, each almost as long as distance between rows; setae on odd-mmbered interstriae largely confined to declivity, rather sparse. long.

Male. - Similar to female except frons with a strong, subdentate median carina on lower two-thirds.

Distribution-California.
USA: California: Eureka. 25 -V and 1-V1, H. S. Barber: Little River, 31-Y-03.

Notes.- The above treatment was based on the holotype, allotype, and three paratypes. A male that possibly may represent this species is from Carmel, California, 4-XII13.

## 75. Pityophthorus sierrensis Bright

Pityophthorus sicrrensis Bright, 1971, Pan Pacific Ent. 47:64 Holotype, female: I mile S Onion Valley, Inyo Co., California: Canadian Nat. Coll.)
Diagnosis.- This species may be a geographical race of nitidus Swaine. It is distinguished from the Oregon population of nitidus by the absence of granules on punctures of the pronotal dise, by the subreticulate elytral dise, and by the slightly different elytral declivity.

Female.- Length 2.0-2.5 mm, 2.7 times as long as wide; color very dark brown.

Frons plano-convex on upper two-thirds, a distinct transverse impression just below middle, then ascending slightly toward epistoma; margins abrupt, separated from margin of eye by distance equal to two to three diameters of a facet; surface shining, densely, rather finely, uniformly punctured; vestiture of fine, abundant, uniformly distributed long hair, only slightly longer at margins, longest setae equal to one-third distance between eyes.

Pronotum as in nitidus except surface subreticulate, discal punctures with lateral margins feebly or not at all armed by granules.

Elytra as in nitidus except surface obscurely reticulate, odd-numbered discal interstriae evidently more sparsely punctured, 2 and 4 without punctures; declivity as in Oregon population of nitidus.

Male.- Similar to female except frons as in some male nitidus.

Distribution.- British Columbia to California and Wyoming.

CANADA: British Columbia: Kooteney Pass 32 km W Creston, 22-IX-67, Pinus albicaulis, D. E. Bright. USA: California: Onion Valley in Inyo Co., 4-IX-68, Pinus balfouriana, and P. flexilis. D. E. Bright. Colorado: Uray, 11-VIl-35, Abies lasiocarpa. Nevada: Wheeler Peak, 8-1X-68, P. aristata, D. E. Bright. Wyoming: Bighorn Mts., 7-VII-75, P. balfouriana, D. E. Bright.

Hosts.-Pinus albicaulis, P. balfouriana, P. flexilis.

Notes. - The above treatment was based on 46 paratypes and on 102 other specimens.

## 76. Pityophthorus aquilus Blackman

Pityophthorus aquilus Blackman, 1928. New York St. Coll. For.. Syracuse, Tech. Pub. 25:33 (Holotype, lemale; Kaibab National Forest, Arizona; U.S. Nat. Mus., 41268)
Pityophthorus caelator Blackman, 192s. New York St. Coll. For., Syracuse, Tech. Pub. 25:78 (Holotype, female; Black Hills, South Dakota; U.S. Nat. Mus., 41293); Bright, 1977, Canadian Ent. 109:514. Synonymy
Pityophthorus aristatae Bright, 1964, Pan Pacific Ent. 40:166 (Holotype, female; Crooked Creek, White Mountains, Mono Co., California; California Acad. Sci.); Bright, 1971, Pan Pacific Ent. 47:67. Synonymy
Diagnosis.- This species is distinguished from the remotely related sierraensis Bright by the strong male frontal carina, by the less extensively, more sparsely pubescent female frons, by the reduced elytral vestiture, and by the more coarsely tuberculate elytral declivity. It is much more likely to be confused with carinulatus, but aquilus is smaller and has the smooth and shining male head and other distinguishing characters.

Female.- Length $1.9-2.2 \mathrm{~mm}, 2.6$ times as long as wide; color very dark brown.

Frons flattened on a semicircular area from epistoma to very slightly above eyes, margin near eye abruptly subangulate, separated from eye by distance equal to or greater than three times diameter of a facet; surface shining, smooth, finely, rather sparsely punctured in central area, more coarsely punctured at margins; vestiture rather sparse, short to
moderately long in central area, conspicuously longer at margins, longest setae equal to one-fourth distance between eyes.

Pronotum 1.1 times as long as wide; outline as in sierraensis Bright; anterior margin armed by about eight rather coarse serrations; posterior areas smooth, shining, punctures rather small, spaced by two to four diameters of a puncture, median line impunctate; vestiture fine, short, sparse, usually absent on disc.

Elytra 1.7 times as long as wide, 1.8 times as long as pronotum; outline as in sierraensis; striae not impressed except 1 near declivity, punctures rather small, spaced by one to two diameters of a puncture, rows often slightly irregular; interstriae about three times as wide as striae, surface almost smooth to obscurely reticulate, odd-numbered interstriae sparsely punctured, even-numbered interstriae usually impunctate. Declivity as in sierraensis except tubercles on declivital interstriae 1 and 3 distinctly larger. Vestiture of minute strial hair, each about equal in length to diameter of a puncture (frequently abraded on disc) and very sparse interstrial hair of about equal length, little if any longer on declivity.

Male. - Similar to female except frons more coarsely punctured, often with a slight impression, median carina sharply elevated from just above epistoma to upper level of eyes (sometimes shorter or longer), usually strongly subdentate on lower half.

Distribution.- California and Alberta to New Mexico.

CANADA: Alberta: Nanton. USA: Arizona: Kaibab N.F. California: Blanco's Corral and Crooked Creek in White Mountains of Mono Co., 16 km N Westgard Pass in Inyo Co., Mt. Lassen. Colorado: Clyde, Colorado N.F., Gould, Larkspur, La Veta Pass, Manitou Mountain, Poudre Canyon, Woodland Park. New Mexico: Capitan Mts., Mimbres, Vermego. South Dakota: Black Hills, Chevenne Crossing, Custer. Utah: Kamas, Logan Canyon, Yellowstone R.S. in Ashley N.F., White Rocks. Wyoming: Buffalo, Lusk, Tensleep.

Hosts.-Picea engelmannii (rare), Pinus albicaulis, P. aristata, P. contorta, P. flexilis, P. ponderosa.

Biology.- This species breeds in twigs and small branches of felled or standing trees.

Notes.- The above treatment was based on the holotypes of aquilis and caelator and on 418 other specimens.

## 77. Pityophthorus lecontei Bright

Pityophthorus lecontei Bright, 1977. Canadian Ent. 109:525 (Holotype, female; Kitt Peak, Pima Co., Arizona; Canadian Nat. Coll.)
Diagnosis.- This species resembles superficially barberi, but is not related. It is distinguished by the strongly convex frons and median carina in both sexes and by the unique declivity. It is more closely related to jeffreyi Blackman.

Female.- Length $1.7-2.2 \mathrm{~mm}, 2.6$ times as long as wide; color rather dark reddish brown.

Frons strongly convex, closely, coarsely punctured, a distinct median carina on lower half.

Pronotum essentially as in blandus Blackman.

Elytral disc much as in blandus except punctures usually more nearly confused. Declivity rather steep, almost flat, a feeble, broad impression from striae 1 to middle of interstriae 3; striae 1 and 2 obsolete, punctures of 3 minute; interstriae 1 weakly elevated, with a few very feeble granules, 2 about three times as wide as 1 , upper half of 3 with a row of very minute granules; surface shining, with dense, obscure, subimpressed points. Vestiture very short, mostly obsolete on declivity.

Male.-Similar to female except frontal carina more strongly elevated, particularly on its upper half.

Distribution.- Arizona and New Mexico to Chihuahua.

USA: Arizona: Kitt Peak in Pima Co., 2-VIIl-68, Pinus cembroides, D. E. Bright. New Mexico: Aragon, Kingston, Las Vegas Hot Springs, Magdalena, Mimbres, Nogal Lake. MEXICO: Chihuahua: 5 km S La Pinta, $5-\mathrm{V}-77$, Pinyon, M. M. Furniss.

Host.-Pinus edulis, P. cembroides.
Notes.- The above treatment was based on the type series of 162 specimens and on one other specimen.

## 78. Pityophthorus brevis Blackman

Pityophthorus bretis Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Pub. 25:81 (Holotype, female; Kaibab National Forest, Arizona; U.S. Nat. Mus., 41295)

Diagnosis.- In some respects this species is variable and difficult to characterize. The male frons is either without a carina or with a weak median carina having its greatest height on the upper half; the female frons is usually plano-convex anth $1.6-2.1 \mathrm{~mm}, 2.6$ times as long as wide; color dark brown.

Frons basically convex, central half planoconvex, epistomal margin distinctly elevated; surface shining, punctures at margins coarse, close, becoming finer on central half, usually impunctate on lower fifth in median area; margins near eye rounded; vestitur: fine, short, sparse, longest setae equal to about one-fifth distance between eyes.

Pronotum 1.0 times as long as wide; widest on basal third, sides weakly arcuate on basal two-thirds, constriction on anterior half very weak, rather broadly rounded in front; anterior margin armed by about six, small, basally separate serrations; posterior areas shining, very obscurely subreticulate in most specimens, punctures moderately fine, mostly spaced by distances equal to one to two diameters of a puncture. Vestiture of fine, rather short hair, absent on median area of disc.

Elytra 1.6 times as long as wide, 1.6 times as long as pronotum; sides almost straight and parallel on basal two-thirds, rather broadly rounded behind; striae not impressed, punctures moderately coarse, rows varying from straight to slightly staggered; interstriae almost smooth, slightly wider than striae, punctures similar to those of striae, moderately spaced, on all interstriae, usually confused with those of striae. Declivity steep, moderately to rather strongly sulcate; striae 1 and 2 obsolete, an occasional puncture sometimes present; interstriae 1 distinctly elevated, armed by a few widely spaced, fine granules, 2 three times as wide as l, broadly, rather strongly impressed, smooth, shining, impunctate, 3 rounded, distinctly higher than 1 , armed by a row of about eight small tubercles. Vestiture of fine, short, semirecumbent strial hair and erect interstrial setae; interstrial setae on disc twice as long as those of striae, about six or more times as long on base and sides of declivity, 2 and usually 1 on declivity glabrous.

Male.- Similar to female except frons more strongly convex, with punctures much larger, median carina present or absent, sometimes extending from epistoma to above eyes, usually with upper half more strongly elevated; declivital sulcus averaging slightly deeper.

Distribution.- Colorado to Durango.
USA: Arizona: Carr Canyon in Huachuca Mountains, Chiricahua Mts., Jacob's Lake, Kaibab N.F., Mt. Lemmon, Pinalino Mts., San Francisco, Santa Catalina Mountains, Walker, Williams. Colorado: Estes Park, Ft. Collins, Pagosa Springs. New Mexico: Capitan Mountains, Cloudcroft, Las Vegas, Luna in Catron Co., Ruidoso, Saudia Mountains, Sapollo. MEXICO: Durango: 96 km W Durango, El Salto.

Hosts.-Pinus ayacahuite, P. edulis, P. ponderosa, P. strobiformis.

Biology.- Specimens were taken from shaded-out branches about $2-5 \mathrm{~cm}$ in diameter.

Notes.- The above treatment was based on the holotype and on 161 other specimens.

## 79. Pityophthorus electus Blackman

Pityophthorus electus Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Bull. 25:I40 (Holotype, female; Ashland, Oregon; U.S. Nat. Mus., 41324)

Diagnosis.- This species is distinguished from solers Blackman by the very different female frons, by the row of sparse, fine punctures on discal interstriae 1 , and by the lateral convexities on the declivity being slightly higher than the suture. It differs from blandus by the finely punctured female frons, by the more finely punctured pronotal disc, and by having the punctures on the discal striae in more nearly regular rows.

Female.- Length $2.2 \mathrm{~mm}, 2.8$ times as long as wide; color reddish brown.

Frons plano-convex to slightly above upper level of eyes, lateral margins obtusely angulate, spaced from margin of eye by distance equal to diameters of two facets; surface shining, very closely, rather coarsely punctured; vestiture of fine, moderately abundant hair of moderate length in central area, twice as long on margins, particularly above, longest setae equal in length to almost half distance between eyes.

Pronotum as in solers except discal punc tures slightly smaller and armed on their lateral margins by a small granule; four median serrations on anterior margin slightly larger.

Elytra as in solers except interstriae 1 with a sparse row of fine punctures on posterior half and lateral convexities on declivity slightly higher than suture.

Male.- Similar to female except frons convex, rather coarsely punctured, a weak median carina usually present from epistoma to upper level of eyes.

Distribution. - Oregon to California.
USA: California: Mt. Hawkins, 23-VI-40, Pinus ponderosa, C. R. Bruck; Mt. Laguna Rec. Area in San Diego Co., 25-V111-68, P. jeffreyi, D. E. Bright. Oregon: Ashland, I6-X-I 4, P. ponderosa, F. P. Keen.

Notes. - The above treatment was based on the holotype and on 26 other specimens.

## 80. Pityophthorus blandus Blackman

Pityophthorus blandus Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Pub. 25:107 (Holotype, female; Argus Mountains, California; U.S. Nat. Mus., 41309)
Pityophthorus singularis Bright, 1966, Pan Pacific Ent. 42:300) (Holotype, female; 12 miles or 19 km W - Lone Pine, Inyo Co., California; California Acad. Sci.); Bright. 1977, Canadian Ent. 109:513. Synonymy
Diagnosis.- This species is remotely allied to brevis Blackman, but it is distinguished by the very different frons in both sexes, by the wrinkled surface on the elytral disc, by the finer elytral punctures, and by other characters cited below.

Female.- Length $1.8-2.0 \mathrm{~mm}, 2.8$ times as long as wide; color very dark brown.

Frons plano-convex from eye to eye, from near epistoma to well above eyes, epistomal margin slightly elevated; surface smooth, shining, punctures coarse, close in marginal areas, distinctly smaller (but still rather coarse) toward central area on lower half, spaced on median area of lower half by about one to two diameters of a puncture; vestiture moderately abundant, almost uniformly distributed, moderately long in central area, becoming very long toward margins, longest setae equal to half distance between eyes.

Pronotum 1.1 times as long as wide; outline about as in brevis except sides almost straight on basal half; posterior areas shining, almost smooth, subobsolete impressed points
visible, punctures fine, spaced by one to two diameters of a puncture. Vestiture obsolete on disc, of minute setae on sides.

Elytra 1.8 times as long as wide, 1.7 times as long as pronotum; outline as in brecis; striae not impressed except 1 slightly near declivity, punctures small, moderately close, rows slightly confused particularly toward base; interstriae at least twice as wide as striae, surface slightly to strongly wrinkled, punctures on all interstriae, similar to those of striae and slightly to moderately confused with them. Declivity steep, rather strongly sulcate; similar to brevis except interstriae 2 four times as wide as 1 , tubercles on 1 and 3 more numerous, two or three supplemental tubercles lateral to 3 near middle of declivity. Discal vestiture of minute strial and interstrial hair of equal length; interstrial setae on lateral areas of declivity conspicuously longer (about half as long as in brevis).

Male.- Similar to female except frons slightly, transversely impressed on lower half, a short, weak median carina in impressed area in most specimens, surface shining, irregular, very coarsely punctured; serrations on anterior margin of pronotum rather long, slender.

Distribution.-California to Colorado and Arizona.
USA: Arizona: Bright Angel Point in Grand Canyon N.P., Flagstaff, Jacob's Lake, Kaibab N.F., Prescott, Santa Catalina Mts., Williams. California: Argus Mountains, Bear Lake, Big Bear Lake, Cajon. Doble, Frazier Mountain in Ventura Co., Lone Pine in Inyo Co., Westgard Pass in Inyo Co. Colorado: Glade Park, Colorado N.F. Nevada: Baker. Utah: Beaver, Iron Mountain in Iron County, Dead Horse Point, Gooseberry area in Fishlake N.F., Monticello, Mercur, Panguitch Lake.

Hosts.- Pinus edulis, P. monophylla, one pair from $P$. ponderosa (accidental?).

Biology.- Specimens were taken from branches and tops about $3-8 \mathrm{~cm}$ in diameter.

Notes. - The above treatment was based on the holotype of blandus, on 6 paratypes of singularis, and on 120 other specimens.

## 81. Pityophthorus cristatus Wood

Pityophthorus cristatus Wood, 1964, Great Basin Nat. 24:68 (Holotype, female; 14 km or 9 miles N Perote, Veracruz, Mexico; Wood Coll.)
Diagnosis.- This unique species is distinguished by the very strongly, broadly excavated declivity, with the lateral convexities
rather spectacularly, subacutely elevated from base to apex.

Female.- Length $1.8-2.2 \mathrm{~mm}, 2.6$ times as long as wide; color dark brown.

Frons convex, somewhat flattened, surface coarsely punctured above and at sides, somewhat more finely punctured below on median half; vestiture inconspicuous, consisting of a few scattered hairs of medium length. Antennal club widest through segment 2, sutures 1 and 2 weakly procurved.

Pronotum 1.05 times as long as wide; sides almost straight and subparallel on basal half, weakly constricted one-third from broadly rounded anterior margin; asperities confused, summit at middle, transverse impression behind summit rather well developed; anterior margin armed by a row of about ten low teeth (somewhat irregular in size); posterior areas subshining, reticulate, punctures deep, close, rather coarse. Vestiture confined to marginal areas.

Elytra 1.7 times as long as wide; sides straight and subparallel on basal two-thirds, then converging very slightly to declivital margin, very broadly rounded behind (median portion almost straight); strial and interstrial punctures confused, punctures moderately large and deep; surface subshining, indistinctly reticulate. Declivity oblique, excavated; an acutely, very strongly elevated subserrulate margin extending above from interstriae 2 to apex, area encompassed approximately obovate; broad excavated area with strial punctures indistinct but evident, in rows, sutural interstriae moderately elevated and bearing a row of close, rounded granules. Vestiture on sides and particularly on declivital margin moderately long and abundant; minute in declivital excavation.

Male. - Similar to female except frons slightly more strongly convex, more coarsely punctured, subglabrous.

Distribution.-Arizona to Michoacán and Veracruz.

USA: Arizona: Chiricahua Mountains, Huachuca Mountains, Santa Rita Mountains. MEXICO: Durango: 37 km W Durango, El Palmito, El Salto. Hidalgo: Tulancingo, Zacatlán. Michoacán: Carapan, 25 km E Morelia, Quiroga. Oaxaca: Oaxaca. Veracruz: Las Vigas, Orizaba, Perote.

Hosts.- Pinus spp.
Biology.- Specimens were taken from broken branches in living trees.

Notes.- The above treatment was based on the type series of 14 specimens and on 45 other specimens.

## 82. Pityophthorus carinulatus Swaine

Pityophthorus carinulatus Swaine, 1925, Canadian Ent. 57:193 (Holotype, male; Tres Ritos, New Mexico; Canadian Nat. Coll., 1369)
Pityophthorus opimus Blackman, 1928, New York St. Coll. For., Syracuse, Tech. Pub. 25:80 (Holotype, female; Capitan Mts., New Mexico; U.S. Nat. Mus., 41294); Bright, 1977, Canadian Ent. 109:514. Synonymy
Diagnosis.- This species is probably allied to the nitidus complex, but it is distinguished by the absence of granules on the margins of the punctures on the pronotal disc, by the absence of punctures on declivital striae 1 and 2 , and by other characters. It is more likely to be confused with aquilus Blackman, but it is distinguished by the larger size, by the strongly reticulate male head, and by other characters.

Female.- Length 2.1-2.4 mm, 2.4 times as long as wide; color almost black.

Frons plano-convex, a low, distinct, obtuse, subcarinate summit on lower fourth to epistomal margin; margins rounded; surface smooth, shining, punctures moderately coarse, close, deep, except less abundant in central area; concealed above upper level of eyes; vestiture of fine hair, rather short in central area, about twice as long at margins, longest setae equal to about one-third distance between eyes.

Pronotum 1.0 times as long as wide; sides almost straight and subparallel on basal third, constriction not evident, rather broadly rounded in front; anterior margin armed by about 10 low serrations; posterior areas finely reticulate, punctures moderately coarse, spaced by one to two diameters of a puncture. Vetiture of fine, short hair.

Elytra 1.6 times as long as wide, 1.7 times as long as pronotum; outline as in borealis; striae not impressed except 1 on posterior half, punctures rather small, mostly in rows; interstriae subshining, obscurely subreticulate at least on basal half, at least twice as wide as striae, punctures absent on 2 and 4 , fine and rather sparse on odd-numbered interstriae, a
few transverse lines on basal half. Declivity rather steep, moderately sulcate; striae 1 and 2 obsolete; interstriae 1 distinctly elevated, sparse granules very fine, poorly formed, 2 almost three times as wide as 1 , smooth with very minute, shallow points, 3 as high as 1 , armed by a row of about six small tubercles. Vestiture of minute, very short strial hair; interstrial hair on declivity short, equal in length to about half width of interstriae.

Male. Similar to female except frons most strongly convex, more coarsely punctured, carina acutely, strongly elevated on lower half, almost subdentate, vestiture sparse, inconspicuous; declivital tubercles smaller.

Distribution.-Alaska to Arizona and New Mexico.

ALASKA: Juneau, 26-V-59, Pinus contorta, D. E. Bright. USA: Arizona: San Francisco Mts., 18-VIll-68, Picea engelmannii, D. E. Bright. Colorado: Clyde, 14-VII-06, Hopk. 6116, and 6117-b (bred 13-IV-06), Picea engelmamii, A. D. Hopkins, Newcastle, Hopk. 31408-J20, P. cngelmannii, C. L. Massey. New Mexico: Capitan Mts., Hopk. 5489, P. engelmannii, J. L. Webb.; Tres Ritos. Utah: Huntington Canyon, I-IX-76, Picea pungens, S. L. Wood.

Host.- Picea engelmannii, P. pungens, two Alaskan males from Pinus contorta.

Biology.- Specimens were reared from shaded out branches $2-7 \mathrm{~cm}$ in diameter.

Notes.- The above treatment was based on the holotypes of carinulatus and opimus and on 24 other specimens.

## 83. Pityophthorus blandulus Schedl

Pityophthorus blandulus Schedl, I955, Zeitschr. angew. Ent. 38:19 (Syntypes, female; Las Trojades, Guatemala; Schedl Coll.)
Diagnosis.- This species is distinguished from ciliatus Blackman by characters of the frons and declivity as described below.

Female.- Length 1.9-2.2 mm, 2.6 times as long as wide; color dark brown.

Frons essentially as in ciliatus except punctures at margins not enlarged, vestiture not longer at sides, only slightly longer above.

Pronotum as in ciliatus except declivity slightly more deeply impressed, much narrower, ascending from striae 1 , declivital setae apparently finer, shorter.

Male.-Similar to female except frons more strongly convex than in ciliatus, a feeble median carina present or absent; declivital sulcus much stronger, lateral convexities higher, their lateral slope much more broadly rounded than in ciliatus male.

Distribution.- Chiapas to Guatemala.
MEXICO: Chiapas: 1.3 km E San Cristóbal. 6-Vi-69, Pinus ochoternai, D. E. Bright. Guatemalat: Las Trojades.

Notes.- The above treatment was based on Bright's homotype and on 27 other specimens.

## 84. Pityophthorus ciliatus Blackman

Fig. 2(K)
Pityophthorus ciliatus Blackman, 1942. Proc. U.S. Nat. Mus. 92:211 (Holotype, female: Jalapa, Veracruz, Mexico; U.S. Nat. Mus., 55986)
Diagnosis.- This species is distinguished from nigricans Blandford by the smaller size, by the less deeply impressed declivital sulcus, and by the greater distance between the female frontal pubescence and the eye.

Female.- Length $1.7-2.1 \mathrm{~mm}, 2.6$ times as long as wide; color very dark brown, elytra usually reddish brown.

Frons plano-convex almost from eye to eve from epistoma to vertex; surface smooth, shining, punctures very fine, close, uniformly distributed; vestiture of abundant yellow hair, moderately long in central area, very long on lateral and particularly dorsal margins, longest setae equal to half distance between eyes.

Pronotum 1.1 times as long as wide; outline as in brevis Blackman, anterior margin armed by about 12 serrations; posterior areas smooth, shining, with numerous impressed points, almost subreticulate in some places, punctures rather small, widely spaced on disc. Glabrous except at margins.

Elytra 1.7 times as long as wide, 1.6 times as long as pronotum; outline as in brevis; striae not impressed, punctures rather fine, in rows, sometimes slightly confused; interstriae smooth, shining, with numerous impressed points, about twice as wide as striae, evennumbered interstriae usually impunctate,
odd-numbered interstriae varying from almost impunctate to regularly punctured. Declivity steep, moderately to rather strongly sulcate; as in brevis except disc glabrous.

Male. - Similar to female except frons broadly convex, rather coarsely, closely punctured, a feeble median carina sometimes present, usually absent, vestiture short, sparse, inconspicuous; declivity of some specimens more deeply impressed.

Distribution.- Veracruz.
MEAICO: Veracruz: Jalapa, 9-II-36, Pimus patula D. DeLeon; Las Vigas, 5-Vil-67. No. 157. Pinus, S. L. Wood.

Host. - Pinus patula.
Biology. - Specimens were taken from branches.

Notes. - The above treatment was based on the holotype and on 53 other specimens.

## 85. Pityophthorus californicus Bright

Pityophthorus deleoni Bright, 1966 (nec Blackman, 1942) Pan Pacific Ent. 42:302 (Holotype, female; Bonnie Doone in Santa Cruz Co., California; U.S. Nat. Mus.)
Pityophthorus californicus Bright, 1976, Great Basin Nat. $36: 42 \%$. Replacement name for deleoni Bright
Diagnosis.- This species is distinguished from nigricans Blandford by the smaller size, by the more narrowly rounded anterior margin of the pronotum, and by the less strongly sculptured declivity.

Female.- Length $1.7 \mathrm{~mm}, 2.7$ times as long as wide; color dark brown.

Frons somewhat plano-convex to well above upper level of eyes, a slight transverse impression evident near middle, epistoma weakly elevated on median half; surface smooth, shining, punctures rather fine, moderately close in upper median area, rather sparse on lower fourth; vestiture of fine, long hair on margins and punctured area, conspicuously longer on margins, length of longest exceeds half distance between eyes.

Pronotum 1.14 times as long as wide; outline about as in nigricans except anterior margin more narrowly rounded, armed by about eight irregularly spaced serrations, posterior area strongly reticulate (obscurely reticulate in allotype), punctures rather coarse, moderately close. Inconspicuous vestiture confined to margins and asperate area.

Elytra 1.8 times as long as wide, 1.6 times as long as pronotum; outline and disc about as in nigricans; declivity similar to nigricans except less strongly impressed, lateral convexities not as high and armed by much finer tubercles, punctures at base on interstriae 2 feebly granulate (not granulate in allotype). Vestiture confined to declivity, similar to nigricans.

Male. - Similar to female except frons more distinctly convex, rather coarsely, more uniformly punctured, with a low, fine, uniform carina extending from epistoma to upper level of eyes; declivity with lateral margins much more strongly elevated (but less so than male nigricans), summit armed by 4-5 fine tubercles, interstrial punctures on 2 at base not tuberculate.

Distribution.- California.
USA: California: Bonnie Doone in Santa Cruz Co., 21-V-41, Pinus attenuata, Hopk. 33689, D. DeLeon.

Notes. - The above treatment was based on the holotype, allotype, and two female paratypes.

## 86. Pityophthorus apachae Bright

Pityophthorus apachae Bright, 1977, Canadian Ent. 109:520 (Holotype, female; Rustler's Camp, Chiricahua Mts., Arizona; Wood Coll.)
Diagnosis.- This species is distinguished from nigricans Blandford by the slightly different frons and declivity as described below.

Female.- Length $2.0-2.4 \mathrm{~mm}, 2.8$ times as long as wide; color very dark brown.

Frons as in nigricans except punctures minute, separated by two to five or more diameters of a puncture.

Pronotum as in nigricans.
Elytra as in nigricans except declivity steeper, more evenly, more strongly arched.

Male.-Similar to female except frons slightly more strongly convex, punctures fine, rather sparse, a distinct median callus at upper level of eyes.

Distribution.- Arizona.
USA: Arizona: Rustler's Camp, Chiricahua Mts., 7 -Vl$69,2600 \mathrm{~m}, \mathrm{No} .79$, Abies concolor, S. L. Wood; Miller Canyon in Huachuca Mts., 23-V1-68, A. concolor, D. E. Bright.

Notes. - The above treatment was based on the type series of 28 specimens and on 29 other specimens.

## 87. Pityophthorus blackmani Bright

Pityophthorus blackmani Bright, 1977, Canadian Ent. 109:521 (Holotype, female; Amecameca, Mexico, Mexico; U.S. Nat. Mus.)
Diagnosis.- Except for the male frons, this species strongly resembles nitidulus (Mannerheim). It is distinguished from the more closely related apachae Bright by the smooth, shining pronotum, by the flatter female frons, with different vestiture, by the more strongly sulcate male declivity, and by the more distinct male frontal carina.

Female.- Length 2.0-2.5 mm, 2.6 times as long as wide; color dark brown.

Frons as in apachae except more distinctly, transversely impressed, vestiture on margins more abundant and much longer, tips of longest setae on vertex exceeding epistomal margin.

Pronotum as in apachae except posterior areas smooth, shining, puntures slightly larger, not distorted.

Elytra as in apachae except disc smoother, shining, strial punctures slightly larger, declivity slightly steeper, slightly narrower.

Male.-Similar to female except frons broadly convex, rather coarsely punctured, smooth, shining, a low, obtuse carina from epistoma to upper level of eyes, elytral declivity more narrowly, much more strongly sulcate, a double or staggered row of tubercles at summit; lateral convexity rising abruptly from position of striae 1 .

Distribution.- Mexico.
MEXICO: Mexico: Amecameca, 28-1-36, 670, Abies religiosa, D. DeLeon.

Notes.- The above treatment was based on the type series of five specimens. All these specimens were treated by Blackman as paratypes of rudis Blackman.

## 88. Pityophthorus micans Bright

Pityophthorus micans Bright, 1981, Ent. Soc. Canada Mem. 118:188 (Holotype, female; Chiltepec, Oaxaca, Mexico; Canadian Nat. Coll.)
Diagnosis.- Allied to nigricans Blandford except differing as described below.

Female.- Length 2.2-2.4 mm, 3.0 times as long as wide; color very dark reddish brown.

Frons largely concealed by pronotum on type, but apparently similar to nigricans.

Pronotum about as in nigricans.

Elytral disc similar to nigricans except strial punctures slightly larger, with sparse punctures on interstriae more numerous (equal in size to those of striae). Declivity similar to nigricans but interstriae 2 slightly wider, much more broadly impressed, ascending rapidly on its lateral third, crest of 3 more abrupt, armed by eight similar denticles, setae almost absent on 2, distinctly longer on 3 .

Male.-Similar to male nigricans except frons more finely punctured, obscure median elevation on lower third only, without callus above; discal punctures on elytra slightly larger, more confused; declivital sulcus more strongly impressed on interstriae 2, particularly on its anterior third (superficially resembling male nitidulus Mannerheim), crest of 3 armed by 10 tubercles, vestiture almost obsolete on 1 , long and conspicuous on 3 .

Distribution.- Oaxaca.
MEXICO: Oaxaca: Chiltepec, I-7i, Pinus montezumae.

Notes.- The above treatment was based on the holotype and allotype.

## 89. Pityophthorus nigricans Blandford

Pityophthorus nigricans Blandford, 1904, Biol. Centr. Amer., Coleopt. 4(6):236 (Lectotype, male; Quiché Mountains, Guatemala; British Mus. Nat. Hist., designated by Bright, I976, Coleopt. Bull. 30:184)
Pityophthorus chiapensis Bright, 1977, Canadian Ent. 109:522 (Holotype, female; I3 km or 8 mi E San Cristóbal, Chiapas, Mexico: Canadian Nat. Coll.); Bright, 1978, Great Basin Nat. 38:72. Synonymy
Diagnosis.- This species is distinguished from nigricans Blandford by the larger size, by the much more deeply impressed declivital sulcus, and by the narrower distance between the female frontal pubescent area and the eye.

Female.- Length 2.2-2.4 mm, 2.8 times as long as wide; color very dark brown, elytra usually reddish brown.

Frons as in ciliatus except lateral margin of impressed area in contact with margin of eye or separated by a distance equal to less than diameter of a facet.

Pronotum and elytral disc as in ciliatus. Elytral declivity as in ciliatus except sulcus deeper, lateral convexities slightly to much higher, summit sometimes almost
subacuminate, tubercles on summit usually larger.

Male.- Similar to female except frons as in male ciliatus except with a distinct, transverse impression near middle, median carina more strongly elevated; declivital sulcus usually deeper, lateral convexities higher.

Distribution.- Durango to Guatemala and El Salvador.

MEXICO: Chiapas: 13 km E San Cristóbal, 8-VII-69, Pinus ayacatite, D. E. Bright. Durango: 5 km W El Salto, 7 -VI-65, 2500 m , No. 40, Pinus, S. L. Wood. GUATEMALA: Quiché Mountains: San Cristobal in Huehuetenango, 28-V-64, 2300 m , Nos. 633, 635, Pinus pseudostrobus, S. L. Wood; Schedl (1955:22) listed Cuchumatanes, Las Trojadas; Quezaltenango, Sierra María Tecum, Totonicapan. EL SALVADOR; Las Pilas, 1976, P. ayacauite.
Biology.- Specimens were taken in branches $2-8 \mathrm{~cm}$ in diameter.

Notes.- The above treatment was based on Blandford's 3 syntypes of nigricans, on the holotype of chiapensis, and on 103 other specimens.

## 90. Pityophthorus lepidus Bright

Pityophthorus lepidus Bright, 1977, Canadian Ent. $109: 526$ (Holotype, female: 5.6 km or 3.5 mi S Suchixtepec on Highway 175, Oaxaca, Mexico: Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from nigricans Blandford by the different frons and declivity as described below.

Female.- Length $1.6-2.5 \mathrm{~mm}, 2.7$ times as long as wide; color dark reddish brown.

Frons as in nigricans except setae slightly less numerous, slightly shorter, longest setae equal in length to almost one-third distance between eyes.

Pronotum and elytra as in nigricans except elytral declivity slightly steeper, more evenly arched, sulcus slightly wider, not quite as deep.

Male. Similar to female except frons more strongly convex, rather coarsely, closely punctured, a distinct, low, median carina from epistomal margin to upper level of eyes.

## Distribution.- Veracruz to Oaxaca.

MEXICO: Oaxaca: 184 km S Oaxaca on Highway I31, $27-30-\mathrm{X}-71,2000 \mathrm{~m}$, Pinus lawsonii, D. E. Bright; 20 km N Oaxaca, 31-V-7I, 3000 m , Pinus, D. E. Bright; 5.6 km S Suchixtepec, 2-VI-71, 2600 m , Pinus, D. E. Bright. Veracruz: Las Vigas, 5-VII-67, No. 157, Pinus, S. L. Wood.

Notes.- The above treatment was based on the type series of 73 specimens.

## 91. Pityophthorus elatinus Wood

Pityophthorus elatinus Wood, 1964, Great Basin Nat. 24:66 (Holotype, female; 5 miles W Ciudad Hidalgo, Michoacán, Mexico; Wood Coll.)
Diagnosis.- This species is distinguished by the unique elytral declivity and by the plano-concave female frons that is ornamented by unusually long reddish brown hair.

Female.- Length 1.8-2.5 mm, 2.9 times as long as wide; color dark brown, elytra usually yellowish brown.

Frons plano-concavely flattened from eye to eye from epistoma to well above eyes; surface smooth with sparse, very fine punctures; vestiture rather short and sparse in central area, long and abundant at margins, longest setae slightly longer than distance between eyes.

Pronotum 1.03 times as long as wide; sides almost parallel on basal half, moderately constricted on anterior half, broadly rounded in front; anterior margin armed by about 12 low serrations; posterior areas irregular, evidently subreticulate with numerous points intermixed, most punctures replaced by small, rounded, isolated granules behind summit, finely and irregularly punctured in lateral areas. Vestiture of fine, short, inconspicuous hair except longer at margins.

Elytra 1.8 times as long as wide, 1.6 times as long as pronotum; outline about as in brevis Blackman; striae not impressed except l weakly, punctures small, close, shallow, in definite rows; interstriae about twice as wide as striae, smooth, impunctate except at margin of declivity. Declivity steep, narrowly sulcate; striae 1 and 2 obsolete; interstriae 1 abruptly, moderately elevated, more strongly below, armed by about 10 minute granules (some may take form of punctures), 2 strongly impressed, smooth, at least twice as wide as 1,3 strongly elevated on upper half, higher than 1 , forming a small hump near middle of declivity causing sulcus to narrow above; wider below, some punctures on elevated portion minutely, indefinitely granulate. Glabrous except at sides.

Male.- Similar to female except frons convex, rather finely punctured, with a fine, low, acute median carina on lower half; declivital convexities much more strongly elevated, unarmed, interstriae 1 bearing a row
of moderately long, stout, semirecumbent setae directed laterad, 3 with a row of short, stout setae on upper third of declivity.

Distribution.- Michoacán to Tlaxcala.
MEXICO: Mexico: Salazor, 16-V11-69, D. E. Bright; Iztaccihuatl-Popocatepetl N.P., 7-V-71, D. E. Bright. Michoacán: 40 km W Ciudad Hidaldo, 16-VII-53, 2800 $\mathrm{m}, 51 \mathrm{~km}$ E Morelia, 14-VI-65, 2900 m , No. 48. Tlaxcala: 17 km N Tlaxco, 9 -VII-67, 2800 m . All were taken from Abies religiosa by me, except as noted.

Host.- Abies religiosa.
Biology.- Specimens were taken from limbs and tops $4-25 \mathrm{~cm}$ in diameter.

Notes.- The above treatment was based on the type series of 7 specimens and on 114 other specimens.

## 92. Pityophthorus speculum Bright

Pityophthorus speculum Bright, 1976, Great Basin Nat. 36:440 (Holotype, female; Cerro Potosí, Nuevo León, Mexico; Canadian Nat. Coll.)
Diagnosis.- This species is distinguished from elatinus Wood by the larger size, by the darker color, and by the elytral declivity as described below.

Female.- Length $1.9-2.7 \mathrm{~mm}, 2.6$ times as long as wide; color very dark brown.

Frons and pronotum as in elatinus except dise without granules.

Elytra as in elatinus except declivity much less strongly impressed, declivital interstriae 1 and 3 each armed by a row of small tubercles, each interstriae on posterior half with a row of rather long, erect setae, most of them twice as long as distance between rows.

Male.- Similar to female except frons as in male elatinus; declivity similar to but more deeply impressed than in female.

Distribution.- Nuevo León.
MESICO: Nuevo León: Cerro Potosí, 3-V-71, 3600 m , Abies, Pseudotsuga menziesii, D. E. Bright.

Notes.- The above treatment was based on the type series of 41 specimens.

## 93. Pityophthorus dentifrons Blackman Fig. 206

Pityophthorus dentifrons Blackman, 1922, New York St. Coll. For., Syracuse, Tech. Pub. 16:125 (Holotype, female; Orono, Maine; U.S. Nat. Mus.)
Diagnosis.- This species superficially resembles ciliatus Blackman but is distinguished by the very different frons in both sexes, by the finer elytral punctures, and by the declivity.

Female.- Length $1.9-2.2 \mathrm{~mm}, 2.5$ times as long as wide; color dark brown.
